It has usually been considered that in lichens there is a mutual effect and that this is more marked in the case of the fungus than in that of the alga, for the fungus can seldom if ever be ascribed to the same species as any free-living form, whilst in many cases the alga has been identified as belonging to some common species. According to some of the earlier workers such as Schwendener the specificity of the lichen was regarded as due to the fungus constituent, the algal gonidia in such different lichens as *Cladonia* spp., *Xanthoria parietina*, and *Parmelia* spp. all belonging to the one species *Cystococcus humicola*.

The recent work of Chodat and his co-workers and of Waren has shown that the algal gonidia cannot be ascribed so readily to free-living species as was previously thought. The conception has been shown clearly by pure culture work, from which it emerges that although the gonidia of various lichens may be of the same general type, for example *Cystococcus*, those isolated from different species of a lichen genus, for example *Cladonia*, are not identical with one another or with the free-living forms and often behave so differently in culture as to be recognisable by the macroscopic form of the colony. It has further been shown by Jaag that similar differences can be recognised between the gonidia isolated from different species of *Parmelia*, and it is especially interesting to find that the different types of *Cystococcus* isolated from *Parmelia* are more like one another than they are to the types of *Cystococcus* isolated from *Cladonia* species.

These facts are a little difficult to interpret and Chodat probably deals with the problem in the simplest way by regarding such different types of gonidial algæ as elementary species. Their identification suggests that the building up of a lichen is by no means haphazard but that it involves the coming together of a definite species of a fungus with a particular type or elementary species of alga and only with this one combination will a lichen of a particular species be synthesised.

Fatigue of Spring Steels

CONSIDERABLE trouble has been experienced by the failure in service of aero engine valve springs. A paper by Swan, Sutton, and Douglas, read before the Institution of Mechanical Engineers on Feb. 20, records an excellent piece of work on the factors which are involved.

The fractures, which were typical of fatigue failure, are ascribed to the stresses set up by 'surging' superposed on the already highly stressed wire, and were in many cases initiated as a result of some slight surface defect. Most of the wires showed surface decarburisation, and the removal of this layer resulted in an appreciable increase in the safe range of stress. Further, the temperature of quenching exerted a marked influence, and where this was high, longitudinal cracks were formed which resulted in premature failure.

Even in those cases where the surface layer had already been removed before heat treatment, the safe limits of stress in fluctuating torsion were still further increased by a further removal of the surface layer after that treatment. The probable causes of this phenomenon appear to be the detrimental effects due to further decarburisation, or the production of minute cracks or both. In steels containing elongated slag inclusions, heat treatment probably results in the formation of cracks at discontinuities and inclusions at the surface.

Another paper was read at the same time by Bateson and Bradley on the fatigue of laminated springs. Tests carried out on complete springs of this type have already shown safe ranges of stress of only 22–40 per cent of those which the materials would withstand in the form of turned and polished specimens. This weakness is clearly due to the surface layers of the plates of which the springs were built up. The thickness of this deleterious layer has now been shown to be quite small. It is practically completely removed by machining 1/16 in. from the surface, and in most cases it is probable that a much thinner layer of 0·01–0·015 in. would be sufficient. This surface effect has been found to be due to the hardening and tempering operations. Only a slight improvement, if any, results from heat treating the springs after the thin layer of steel has been removed from the surface of the rolled plate.

University and Educational Intelligence.

LONDON.—A course of five weekly lectures, which began on April 21, is being given by Sir John A. R. Marriott, on "The English in India, being the Essentials of the Indian Problem". The lectures are taking place in the University of London, Imperial Institute Road, South Kensington, S.W., and have been arranged by the University Extension Committee of the University. The first lecture was entitled "The Indian Background", this will be followed in succeeding weeks by lectures on "The English in India", "Constitutional Evolution under the Company", "Constitutional Evolution under the Crown", and "The Problem of India".

THE Quinquennial Congress of Universities of the Empire will be held next July. The main proceedings will take place in Edinburgh, but before this, several days will be spent in London by the delegates, where they will be received by the Prince of Wales at Guildhall on July 3. The London programme will include receptions by the League of Nations Union, the Victoria League, the English Speaking Union, and the University of London. Visits will also be made outside London, including the Universities of Oxford and Reading. The Congress will begin in Edinburgh on July 7. Addresses will be given by the Lord Provost of Edinburgh, Sir Donald Macalister, chancellor of the University of Glasgow, Lord Meston, chancellor of the University of Aberdeen, and Lord Beauchamp, chancellor of the University of London. Several subjects of general academic interest will be discussed, including "The University Graduate in Commerce and Industry", the standard and the conditions of candidature for Ph.D. in relation to other post-graduate qualifications, conditions of admission to Universities and their effects, the provision of schemes of study leading to general honours degrees, post-graduate study in medicine and surgery in Great Britain, and facilities for overseas students in British universities.

Birthdays and Research Centres.

April 26, 1879.—Prof. O. W. RICHARDSON, F.R.S., director of research in physics at King's College and honorary professor of physics in the University of London, Yarrow research professor of the Royal Society.

The researches to which I am now devoting most energy concern:

(1) The spectrum of hydrogen (H_2). This is of fundamental importance and interest owing to the simplicity of the structure of H_2 (2 protons and 2 electrons) and the richness of the spectrum. These researches have already provided the most accurate confirmation of the application of wave mechanics to a problem involving the interaction of more than two bodies. Mr. Williams and I have recently found that various band lines have different fine structures. In addition to its intrinsic interest, this should help to clear up the unclassified part of the spectrum.

(2) Soft X-rays. My chief immediate object here is to try to account for the puzzling discrepancy between the results got by optical and photoelectric methods.

(3) Electric emission resulting from chemical action. We have made great progress lately with this phenomenon, which, I think, is destined to shed much light on the nature of chemical action generally.

April 27, 1845.—Dr. D. W. FRESHFIELD, sometime president of the Alpine Club, the Royal Geographical Society, and of Section E (Geography) of the British Association.

I am chiefly interested in geographical education at the universities, and especially at Oxford.

May 1, 1882.—Prof. R. RUGGLES GATES, professor of botany in the University of London (King's College).

The lines of work now being carried on in my laboratory are mainly concerned with cytology and genetics, although work on plant physiology and biochemistry is also being done. Two investigators are working on the structure of chromosomes, and how and when the split takes place in mitosis. Another is investigating the floral development and cytology of the Australian acacias; another, the phenomena accompanying zygospore formation in Mucors, where it has been shown that, in certain cases at any rate, the medium plays a part in determining the conjugation or non-conjugation of two strains.

We are continuing on an extended scale the cytogenetic work with *Œnothera*, especially as regards chromosome linkage and the production of haploids. Several of my staff and students are partly engaged in this work, which promises to give further insight into the relations between chromatin and heredity.

As time and opportunity permit, I am continuing my work on heredity in man, racial crossing, and blood groups from anthropological, genetical, and eugenical points of view. An immediate need is the determination of the blood groups in the Siwash and other tribes of Indians in British Columbia.

May 2, 1868.—Prof. R. W. WOOD, For.Mem.R.S., professor of experimental physics, Johns Hopkins University, Baltimore.

Investigations of the absorption spectra of salts in anhydrous liquid ammonia are in progress, and certain new filters or colour screens for spectroscopic work have been found. Rather remarkable effects have been found with neodymium ammonium nitrate, the band in the yellow shown by a water

solution breaking up into five narrow components in the case of ammonia solutions A solid solution of neodymium oxide in fused quartz gives a most remarkable temperature emission spectrum, a fibre held in a Bunsen flame and viewed with a direct vision prism shows four bright bands (two red, an orange, and a green), separated by almost perfectly black intervals Eight bands have been photographed between wave-lengths 4000 A and 11,000 A

Work is going on also with the Raman effect The best filter for removing the line Hg 4046 is a solution of quinine in very dilute sulphuric acid It can be prevented from turning yellow (its chief objection) by a thin sheet of Corning noviol glass specified to absorb λ3650 and transmit λ4358 For removing the 4358 line a solution of iodine in carbon tetrachloride of proper concentration is used I now work with a horizontal quartz arc in a metal box, with the filter solution in a glass tube 6 cm in diameter and 25 cm long mounted horizontally between the arc and the tube containing the solution under investigation An electric fan blows the hot air column from the burner to one side

Societies and Academies

LONDON

Physical Society, Mar 6 —**G M B Dobson** A photoelectric spectrophotometer for measuring the amount of atmospheric ozone The instrument follows the usual practice of measuring the absorption by the ozone of solar ultra violet energy, from this measurement the amount of ozone can be deduced A double quartz monochromator isolates certain pairs of wave lengths, and the relative energy in the two wave lengths of a pair is measured by allowing them to fall alternately on to a photoelectric cell, the current from which is amplified by thermionic valves This allows great sensitivity to be obtained, so that very small amounts of light can be accurately measured For measuring the amount of ozone, a pair of wave lengths, one of which is strongly absorbed by ozone while the other is not, is selected It is shown how the amount of ozone can still be measured when the sky is cloudy if a second pair of wave-lengths, both unabsorbed by ozone, be also measured

EDINBURGH

Royal Society, Mar 2 —**B Prashad** Some noteworthy examples of parallel evolution in the molluscan faunas of south eastern Asia and South America The three families specially studied in this connexion are the Pilidæ (Ampullaridæ), Unionidæ, and Ætheriidæ In all three families there are species, externally almost identical, found in the two areas mentioned living under similar ecological conditions These almost identical types are believed to be the result of the action of the environment alone, and are regarded as examples of parallel evolution —**Henry Briggs**. The classification and development of the Carbonaceous minerals of organic origin A classification, based on the ultimate analysis, is applied to coals, cannels, paraffin shales, and torbanites All analyses are reduced to the basis C + H + O = 100 per cent A graphical method of presenting the analyses is adopted, it shows the above minerals to be distinct species, each following a 'development line' which expresses the evolution of the mineral from a rank equivalent to lignite to a rank equivalent to semi-bituminous coal With the exception of that of ordinary coals, the 'development lines' are straight, and each is oriented to a deoxygenated end-product of simple composition —**H V Lowry** Properties of the function $Ei_n(x)$ the function $\int_1^\infty \exp(-xt)t^{-n}dt$ which Milne called $Ei_n(x)$ in his book "Thermodynamics of the Stars", has also been used by Gold and Roberts in the discussion of some radiation problems In this paper some of the main properties of the function are discussed, including recurrence properties, expansions of the function in series, an approximation for large values of n, and a method of using least squares to find a function of the form $a\exp(-bx)$ which shall be close to $Ei_n(x)$ for all positive values of x —**A C Aitken** and **A Oppenheim** On Charlier's new form of the frequency function The probability, or relative statistical frequency, of a wide class of variables has been represented by the 'series of type A' The series is known, however, to have the practical defect that its terms do not decrease in regular succession, and C V L Charlier has recently advanced a modified form, type C, which he proves to be free from the defect in question, for the first several terms at least The authors demonstrate the truth of Charlier's conjecture that all the terms decrease in order Indirectly some abstruse theorems in combinatory algebra are brought to light

PARIS

Academy of Sciences, Mar 9 —**Mesnager** The bending of a beam does not depend on the shearing stress —**V Grignard** and **J Savard** The magnesium derivatives of dichlorotriphenylphosphine and on the pentaphosphines The chloride $C_6H_5\ PCl_2$ treated with the magnesium compound RMgX gives $C_6H_5PR_2$ The preparation and properties of $(C_6H_5)_3PCl_2$ are described, and also a new class of phosphorus compounds, the pentaphosphines, of the type $(C_6H_5)_3PR_2$, where R is an alkyl group —Elie Cartan was elected a member of the Section of Geometry in succession to the late P Appell —**Francesco Severi** A fundamental property of analytical functions of several variables —**Radu Badesco** Solution of a functional equation and generalised iterative functions —**Soula** Functions which possess an infinity of derivatives —**Basile Demtchenko** The inverse mixed problem and surfaces of sliding in doubly connected space —**O Yadoff** A new method of establishing the normal working diagram of turbines —**V G Siadbey** The apparent radiants of large meteors —**T Boggio** A physical interpretation of Riemann's tensor and of the principal curvatures of a variety V_3 —**P Vernotte** and **A Jeufroy** A simple method of measuring the specific heat of a solid at the ordinary temperature Application to beryllium The substance, at room temperature, is dropped into water at 1°–2° C contained in a Dewar vessel The calorimeter is standardised with a mixture of water and mercury of the same volume and heat capacity as the body under examination —**V Lalan** The hypothesis of the curve of pursuit and the laws of reflection in optical systems in motion —**R Jouaust** The problem of heterochrome photometry —**R Ricard** The various spark spectra of mercury —**G A Boutry** Modifications of the characteristic surface of a photoelectric cell with a gaseous atmosphere when the resistance in series is changed —**Guichard, Clausmann, Billon, and Lanthony** The independence of the hardness and proportion of hydrogen in electrolytic metals From the experiments described, the authors conclude that electrolytic metals do not owe their hardness, even partially, to the presence of a hypothetical hydride, their hardness is due to their very fine structure —**Néda Marinesco** Specific inductive power and molecular weight It is possible to deduce the molecular weight of a

dissolved colloid by a study of the dielectric dispersion of the system as a function of the wave-length Applied to a dilute solution of gelatine, the value for the molecular weight found was 11,300 —L Joleaud The recent progress of our knowledge on the history of the Pacific in the Tertiary period and Wegener's theory —D Schnéegans Observations on the western limit of the Briançonnais sheet to the south of the Maurienne —Mihailovitch Jélenko Two earthquake catastrophes, in November 1930 and January 1931, in Albania —Emile F Terroine and Miles Germaine Boy, Marguerite Champagne, and Gilberte Mouret The distribution of urinary nitrogen in the endogenous nitrogen metabolism specific during growth —Louis Baudin The respiratory quotient of fish as a function of temperature —Marcel Abeloos and Maurice Lecamp The production of abnormal and multiple formations in the limbs of Triton by the transplantation of regenerates —F Vlès and A de Coulon The final end of grafts of arrested epithelial tumours

SYDNEY

Royal Society of New South Wales, Dec 3 —**A R Penfold** The essential oils of three species of *Geijera* and the occurrence of a new hydrocarbon The essential oils from *Geijera parviflora*, *G Muelleri* and *G salicifolia* were examined Apparently two physiological forms exist in the species *parviflora* A new hydrocarbon of tentative formula $C_{11}H_{18}$ was isolated and several of its characteristics were examined —**J G Churchward** Studies in the inheritance of resistance to bunt in a cross between Florence and Hard Federation wheats Resistance to bunt is inherited as a simple Mendelian recessive A study of the occurrence of grass tufts in the progeny of the cross indicates the presence of an inhibiting factor A single dominant factor determines the inheritance of tip beardedness In the cross, Florence × Hard Federation, the inheritance of resistance to bunt, grass tufts, and tip beardedness is controlled by single, independent, Mendelian factors —**M B Welch** (1) Experiments on moisture in timber Experiments on the moisture content at different times of the year of certain flooring timbers at Sydney, show that a variation of approximately 2 0 per cent occurs between the maximum and minimum results The mean moisture content of twenty-six samples was 12 7 per cent, although individual samples varied from 14 8 to 10 1 per cent at different periods The mean moisture content of the softwoods is in general lower than that of hardwoods, which seldom give a mean figure below 12 5 per cent —(2) The occurrence of intercellular canals in the wood of some species of *Flindersia* Longitudinal intercellular canals of a gummosis type occur in the secondary wood of some species of *Flindersia*, notably *F Brayleyana* They are found in metatracheal parenchymatous bands, and form a more or less anastomising network extending in a tangential direction but not radially The contents appear to be similar to wound gum, the canals being formed by the breaking down of the cell walls Their origin is usually schizo lysigenous

VIENNA

Academy of Sciences, Jan 15 —**G Aigner** A graptolite fauna from the graywacke zone of Fieberbrunn in Tyrol, with remarks on the graywacke zone of Dienten Of 1200 specimens, some three per cent could be determined, thus ranking the shales with zones 18 22 of the English Silurian according to Elles and Wood —**B Kubart** Investigations on the flora of the coal basin of Ostrau-Karwin A *Lyginodendron* with marked medullary structure and zones of increase —**O Schindler** A new *Hemirhamphus* from the Pacific Ocean —**O Koller** The mammalian fauna of the Pithyusæ Islands —**A Steuer** Variation of size and form in the plankton copepods —**A Tamerl'** The osculating cylinder of rotation to a given three-dimensional curve —**J Hoffmann** The causes of different radiation colourings in glasses and of silic[illegible] and amethyst colourings —**W Abel** Investigations on the separate inheritance of the size of jaw and size of teeth in half-breeds from Bushmen, Hottentots, and Negroes The canines are sometimes crowded This is supposed to be due to the crossing of a large-toothed race with a small-jawed race The jaw is mesodermal, the teeth are ecto-dermal in plan —**K Menger** The concept of constructivity (2) The construction of series of arithmetical numbers

Jan 22 —**K Spitzer** Specific dopa-oxydases extracted from fruit In apple, pear, and banana there is a di-oxy-phenyl derivative which is most probably identical with 'dopa' (=di oxy-phenyl-alanin) —**E Schmid** The radium emanation content of open air and its vertical distribution near the ground (from observations in St Peter, near Graz, in 1930) The average content was less at a height of 50 metres than at 13 metres or 2 metres Also, the radium emanation concentration varied with meteorological conditions —**J Pia** Preliminary report on fossil Algæ, the results of a journey to England with the support of the Academy of Sciences The carboniferous limestone was studied in the field, in Gloucestershire, Yorkshire, and Westmorland, also in the museums of Bristol, Leeds, and London —**W Laves** Physico chemical studies of colour after experimental injury to the liver (1) The alteration of the electrostatic characters of nucleus chromatin and plasma of liver cells from injuries of the circulation and from direct action of high and low temperatures on the liver —**V Lebzelter** The anthropology of the Kung Bushmen Two main types and an intermediate were found

WASHINGTON, D C

National Academy of Sciences (*Proc*, Vol 16, No 12, Dec 15) —Biotic cementation in coral reefs A distinction should be drawn between calcareous reefs and reefs actually built up by the co-operative growth of coral colonies, the skeletons of which become their chief component The Darwinian theory of coral reef growth refers to the second type of reef The solidarity of these reefs depends on organic cementation and the organisms concerned are nullipores —**W E Castle** The quantitative theory of sex and the genetic character of haploid males Certain hymenoptera, scale insects, and rotifers produce males which arise from unfertilised reduced eggs and transmit in their sperm only the female sex tendency It is concluded that they are genetically females though functionally they are sperm producers and are called males on the basis of their somatic character.—**Barbara McClintock** A cytological demonstration of the location of an interchange between two non-homologous chromosomes of *Zea mays* —**Sterling Emerson** The inheritance of *rubricalyx* bud colour in crosses with *Œnothera Lamarckiana* —**Harold H. Plough** Complete elimination of self-sterility in the ascidian *Styela* by fertilising in alkaline solutions. The block to self-fertilisation appeared to reside in the egg cortex itself —**G I Lavin** and **J R Bates**. The ammonia discharge tube An active gas is produced which is reducing in character, heats small solid particles in its path to incandescence, and causes an intense green glow in the ammonia collected in the liquid air trap Different metal and oxide surfaces show different effects in extinguishing the glow. The active gas seems to be a mixture of atomic hydrogen and a hydride of nitrogen (NH or NH_2).—**R. M.**

Badger and J W. Urmston: The separation of the two types of iodine molecule and the photochemical reaction of gaseous iodine with hexene Iodine and hexene were exposed to intense radiation from a mercury arc Compared with another tube containing fresh iodine and hexene, the experimental tube showed much weaker fluorescence with a mercury arc, suggesting that the type of iodine molecule responsible for this fluorescence had largely combined with the hexene —**George Scatchard** Note on the equation of state explicit in the volume —**Y H Woo** On the intensity of total scattering of X-rays by monatomic gases (see NATURE, Oct 4, 1930, p 501) —**H Bateman** Irrotational motion of a compressible inviscid fluid The discussion is applied to the case when the velocity is greater than the local velocity of sound and to the circulation round an aerofoil —**W J Trjitzinsky** A study of indefinitely differentiable and quasi analytic functions —**Tracy Yerkes Thomas** On the unified field theory (2) Another set of field equations is derived which indicates that Maxwell's equations hold approximately in the local co ordinate system in the presence of weak electro magnetic fields

Diary of Societies.

FRIDAY, APRIL 24

ROYAL SOCIETY OF ARTS (Indian Meeting) at 4 30 —Sir William Foster John Zoffany in India.

ROYAL SOCIETY OF MEDICINE (Disease in Children Section) (at Westminster Hospital), at 4 30

INSTITUTE OF MARINE ENGINEERS, at 6 —Annual General Meeting

INSTITUTION OF ELECTRICAL ENGINEERS (London Students Section), at 6.15 —E J Mathieson The Generation and Uses of Electrical Power in a Modern Colliery

SOCIETY OF CHEMICAL INDUSTRY (Chemical Engineering Group) (Annual General Meeting) (at Waldorf Hotel, Aldwych) at 6 45 —At 7 30 —Sir Richard Gregory Bart Science in Industry

BRITISH ASSOCIATION OF CHEMISTS (Scottish Section) (at Central Halls Glasgow), at 7 30 —Annual General Meeting

ROYAL SOCIETY OF MEDICINE (Epidemiology and State Medicine Section), at 8 —Col L W Harrison Epidemiology of Venereal Diseases

ROYAL INSTITUTION OF GREAT BRITAIN at 9 —Sir Philip Hartog Joseph Priestley and his Place in the History of Science

SATURDAY APRIL 25

NORTH OF ENGLAND INSTITUTE OF MINING AND MECHANICAL ENGINEERS (at Newcastle upon Tyne), at 2 30 —T C Futers Notes on a Recent Visit to South Africa with the Empire Mining and Metallurgical Congress Witwatersrand Gold Mines Coal, Asbestos, and other Mines Diamond Mines (Lecture).—Paper open for further discussion —Old Mining Records and Plans T V Simpson

INSTITUTE OF BRITISH FOUNDRYMEN (Lancashire Branch) (at College of Technology, Manchester), at 4 —E Ronceray Sand, and Sand Preparation

MONDAY, APRIL 27

INSTITUTE OF ACTUARIES at 5 —K J Britt Amalgamations of Life Assurance Companies.

ROYAL INSTITUTE OF BRITISH ARCHITECTS at 8 —M Ayrton Modern Bridges.

ROYAL SOCIETY OF ARTS at 8 —Dr N A V Piercy The Present Position in Aeronautics (Howard Lectures) (3).

ROYAL SOCIETY OF MEDICINE (Odontology Section), at 8 —W Charles Full Denture Prosthesis

TUESDAY, APRIL 28

EUGENICS SOCIETY (at Linnean Society) at 5 30 —Dr A J Lewis Genetic Problems in Psychiatry

ZOOLOGICAL SOCIETY OF LONDON, at 5 30 —Dr W E Le Gros Clark The Brain of *Microcebus murinus*.—C Elton, E B Ford, J R. Baker, and A D Gardner The Health and Parasites of a Wild Mouse Population —Dr C J van der Klaauw On the Tympanic Region of the Skull in the Mylodontinæ —R Anthony Vestiges de deux remplacements successifs de la 3ème molaire de lait chez l Eléphant d Asie (*Elephas indicus* Cuv).—D Aubertin Revision of the Genus *Hemypyrellia* Tns (Diptera Calliphoridæ).

INSTITUTION OF CIVIL ENGINEERS, at 6.

INSTITUTE OF INDUSTRIAL ADMINISTRATION (at 28 Portland Place, W 1), at 6 30 —H Lesser and others Discussion on Personnel Policy and Administration

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN at 7 —Symposium on Sensitometry —Dr W Clark General Considerations of Sensitometry as Applied to Sound Recording —C R. Keith Sensitometry in the Modern Film Laboratory —G S. Moore Precautions in Practical Sensitometry —Miss G Geoghegan Demonstration of the Tallent Reflection Density Comparator

QUEKETT MICROSCOPICAL CLUB (at 11 Chandos Street, W 1), at 7 30.—Gossip Meeting

ROYAL ANTHROPOLOGICAL INSTITUTE, at 8.30 —A L. Armstrong Recent Excavations in the Pin hole Cave, Cresswell Crags

ROYAL AERONAUTICAL SOCIETY (Students Section).—E Wieser Airships (Lecture).

WEDNESDAY, APRIL 29

BRITISH ASTRONOMICAL ASSOCIATION (at Sion College), at 5

GILBERT WHITE FELLOWSHIP (at 6 Queen Square, W C 1), at 6 —Miss Evelyn Cheesman In the Savage South Seas (Lecture).

ROYAL SOCIETY OF ARTS, at 8 —Sir Harold Carpenter Stainless Metals

THURSDAY, APRIL 30

ROYAL SOCIETY, at 4.30 —Dr A. E H Tutton Determination of the Yard in Wave Lengths of Light.—U R. Evans, L. C Bannister, and S C Britton The Velocity of Corrosion from the Electrochemical Standpoint.—T L. Eckersley On the Connexion between the Ray Theory of Electric Waves and Dynamics.

LINNEAN SOCIETY OF LONDON, at 5 —Dr G S Carter Aerial and Aquatic Respiration —Dr E S Semmens Hydrolysis in Living Plants by Polarised Light Effect of Blue Skylight on Plant Metabolism —Dr J M Dalziel Hairs Lining the Loculi of Fruits of Species of *Parinarium*

INSTITUTION OF ELECTRICAL ENGINEERS at 6 —Presentation of the Faraday Medal to C H. Merz —Prof W L Bragg The Architecture of Solids (Kelvin Lecture).

INSTITUTION OF LOCOMOTIVE ENGINEERS (at Institution of Mechanical Engineers), at 6 —Miss V W Holmes A New and Infinitely Variable Poppet Valve Gear

ROYAL AERONAUTICAL SOCIETY (at Royal Society of Arts), at 6.30 —Dr M Curry Aerodynamics of Sails (Lecture)

FRIDAY, MAY 1

CERAMIC SOCIETY (Building Materials Section) (at Imperial College of Science and Technology), at 10 30 A M —M Barrett Night Architecture —W A McIntyre Durability of Terra Cotta with Particular Reference to the Filling of Blocks —M Barrett Stock Terra Cotta —M Barrett Metallised Terra Cotta —At 2 30 —E R F Cole Kiln Products in Architecture —G Haworth Informal Talk on Modern Machinery Used in Three Processes of Brick making, i e Semi plastic, Stiff plastic, and Plastic Wire Cut.—W Emery Notes on the Firing of a Blue Brick Oven

ROYAL SOCIETY OF MEDICINE (Otology Section) (Annual General Meeting) at 10 30 A M —Dr Schmaltz The Physical Phenomena Occurring in the Semi circular Canals during Rotatory and Thermic Stimulation —Dr H W Barber Eruptions Involving the External Auditory Meatus —Discussion Non malignant Diseases of the External Ear and Auditory Meatus

ROYAL ASTRONOMICAL SOCIETY (Geophysical Discussion), at 4 30 —Dr G M B Dobson Variations and Distribution of Atmospheric Ozone

PHYSICAL SOCIETY (at Imperial College of Science), at 5 —Prof J E Lennard Jones Cohesion (Lecture).

ROYAL INSTITUTION OF GREAT BRITAIN at 5 —Annual Meeting

ROYAL SOCIETY OF MEDICINE (Laryngology Section) (Annual General Meeting), at 5 - Prof G Portmann A Big Tumour of the Deep Regions of the Face Removed by Operation, with Cure —Dr A Brown Kelly, Dr D R Paterson, and others Discussion on Obstruction at the Upper End of the Œsophagus (Excluding Pharyngeal Diverticula)

ROYAL SANITARY INSTITUTE (at Town Hall Batley), at 5 —Councillor H Crothers and Councillor H S Houldsworth Housing, with Special Reference to the Housing Act, 1930, from the Aspect of a Town Councillor —Dr T Gibson and H Hornby Housing, with Special Reference to the Housing Act, 1930 from the Administrative Standpoint

NATIONAL INSTITUTE OF INDUSTRIAL PSYCHOLOGY (at Royal Society of Arts) at 6.—Miss S. Bevington The Causes of Juvenile Drifting —A. H Seymour Personnel Work in Modern Industry

INSTITUTION OF ELECTRICAL ENGINEERS (Meter and Instrument Section) at 7 —Prof W M Thornton High Voltage Precision Measurements (Lecture).

INSTITUTION OF MECHANICAL ENGINEERS (Informal Meeting), at 7 —H Crowe and others Discussion on Hydraulic Valves

GEOLOGISTS' ASSOCIATION (at University College), at 7 30 —Prof P G H Boswell The Glacial Deposit of East Anglia, with Especial Reference to the Industries of Early Man

ROYAL SOCIETY OF MEDICINE (Anæsthetics Section), at 8 30 —Annual General Meeting

ROYAL INSTITUTION OF GREAT BRITAIN, at 9 —Prof D Arcy W Thompson Charlotte Brontë in Brussels.

SATURDAY, MAY 2

ROYAL SANITARY INSTITUTE (at Town Hall, Batley), at 10 A M —Major D S Rabagliati and others Discussion on The Practical Value of Meat Inspection

INSTITUTION OF ELECTRICAL ENGINEERS (Meter and Instrument Section) (at Cambridge).

PUBLIC LECTURES

TUESDAY, APRIL 28

LONDON SCHOOL OF ECONOMICS, at 5 —Prof L. Hogben Some Aspects of Human Inheritance (1) The Biology of Twinning

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE (Public Health Division), at 5 —Prof F A E Crew Laws of Inheritance (Succeeding Lectures on April 29, 30, and May 1)

WEDNESDAY, APRIL 29

UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL, at 5 30 —Prof O Förster Neurology (Succeeding Lectures on April 30 and May 1)

THURSDAY, APRIL 30.

UNIVERSITY COLLEGE, LONDON, at 5 30 —M Aubert Les origines de la Voûte sur Croisée d Ogives. (Succeeding Lecture on May 1)

FRIDAY, MAY 1

UNIVERSITY COLLEGE, LONDON, at 5.—Prof B Ashmole History of Ancient Sculpture

SATURDAY, MAY 2, 1931

Medicine and Science.

THE advancement of medicine is an object which can scarcely fail to be universally desired, and the discussion of the principles that govern it is therefore a matter of perennial interest It is in itself an evidence of healthy life that such discussion should have been active of late and should have been contributed to influentially from several different aspects *

The fundamental process at work in progressive medicine to day is the gradual acquisition by it of the qualities of an applied science Although this development must be regarded as the inevitable course of sound advance, it is beset by certain difficulties inherent in the very nature of the case which give to the situation of medicine a special interest from the point of view of method One of these difficulties is the result of what we may call the historical setting in which science applied to medicine finds itself

When science is given a wholly new contact with practical affairs, the applied science that thereupon grows up develops, as it were, in virgin soil, with nothing to hope from the co operation or to fear from the conservatism of any antecedent practical art in the same field In these circumstances, the new activity may develop uneventfully as a straightforward applied science, such, for example, has been, from this point of view, the situation of electrical engineering When science is applied to a field already occupied by a vigorous practical art, however, the contact of the two different disciplines may result in a certain wasteful discrepancy of ideals and effort In some degree this has been the situation of scientific agriculture in its relation with the ancient practical art of farming, it is still more clearly the situation of applied science in medicine Here science finds the ground already occupied by one of the most ancient, vigorous, and learned of the practical arts It must be recognised that the two disciplines, although in favourable circumstances capable of most fruitful co-operation, do not possess any strong natural affinity for one another One of the aspects of this relative incompatibility is shown in the inveterate endeavour of science to bring every individual problem within the range of principles of general validity, while the strength of the practical art is its regard for the uniqueness of the individual case

* The following contributions may be mentioned both for their importance and their representative variety of outlook Observations on Research in Medicine , by Sir Thomas Lewis, *Brit Med Jour*, Mar 15, 1930, "A Discussion on Research in Clinical Medicine" by Dr J Ryle and others, *Proc Roy Soc Med*, Oct 28, 1930, "The Science of Medicine", by Lord Moynihan, the *Lancet*, Oct. 11, 1930

A second obstacle that applied science in medicine has to overcome is inherent in the biological situation of man. It is the consequence of the wide gap in structure, and still more in function, that separates man from any other animal. The extent of this separation has perhaps not always been fully recognised; it is, however, undoubtedly of importance, not only in complicating the application to man of the results of animal experiment, but also because of the doubt it raises whether certain activities of man on which knowledge is urgently needed by medicine can even be illustrated, much less elucidated, by experiments on animals. The recognition of this difficulty has caused greater and greater attention to be given to the use of direct experimentation in man himself—the only means of acquiring knowledge about him that from the point of view of method is wholly unexceptionable. It is, however, of necessarily limited range, so that for the general progress of knowledge in scientific medicine we must continue to depend chiefly on animal experiment and on our ability to apply its results to man.

Although man's place in Nature has been and still is a favourite theme of the post-Darwinian biologist, it has, for reasons historically obvious, very naturally been defined chiefly with an eye to structure and to unities and resemblances with the rest of the living world. The time has now come when in the interests of medicine a more exact and critical orientation is necessary, which must concern itself essentially with function and not less with dissimilarities than with likenesses. On the elaboration of such a science of comparative function in health and in disease the progress of medicine is likely to come more and more to depend. Much of the material for such a study exists already in the immense accumulation of the facts of human behaviour made by clinical medicine from time immemorial.

In this connexion, some comment on the general value of the clinical method as an implement of research should perhaps be made. There can be no doubt that, as a method of fundamental inquiry, that characteristic of the clinical physician has been far outdistanced by that of strict scientific experiment. This fact has led to the suggestion that the time honoured method of the clinician, the method of Addison and Bright, of Paget and Hughlings Jackson, has little or nothing to offer for the future of medicine. Since the acceptance of this doctrine could scarcely fail to have important practical consequences, some examination of it is desirable. The great strokes of the clinical method have usually been made by the use of observation acute and patient rather than systematic, with a certain amount of not very strict experiment, both guided by a penetrating intuition and a profound familiarity with the subject of inquiry. These successes have therefore been won by men whose mental powers enabled them to use an imperfect instrument with a certain large indifference to its defects. Lacking the intuition of his great predecessors, the clinical worker must pay more attention to perfecting the instrument if he is to get substantial results. Every opportunity to introduce standards of scientific severity must be taken, observation must be systematic and exact, and the most must be made of any occasional chance to submit an issue to experiment. Purely clinical inquiry never has been and never can be the equal of experiment in the attack on a problem stage by stage until a final solution is reached, but if every opportunity is taken to naturalise in it standards of scientific severity, it has within its range innumerable important problems that it should be thoroughly able to solve.

Whatever successes may await a clinical medicine thus oriented more definitely towards the standards of science, there can be no doubt that it is the experimental method, in all its severity and in the hands of the appropriately educated expert, on which the substantial progress of medicine essentially depends. How best this great instrument can be directed upon the work before it is a matter on which very naturally there is difference of opinion. Perhaps the most important practical problem yet in discussion is to decide the relative claims of what have been called 'free' research and 'directed' research: that is to say, inquiry which follows the natural evolution of its subject, and inquiry in which specific problems are allotted to the worker for solution. There can be no question that in the sciences on which medicine depends, as in all other sciences, complete freedom of research is indispensable; however academic, however remote from any kind of usefulness inquiry following its own course may seem to become, any restraint, in the supposed interests of practical ends, is wholly inadmissible. There is, however, another aspect of the case which must be considered. The practical clinician finds himself surrounded by problems which seem soluble by skilled experiment and of which solutions are urgently necessary in the interests of his art. He sees that the great bulk of research in physiology and even pathology has little or no direct bearing on his immediate difficulties. Aware as he is that one of the most effective

instruments used by these sciences—operative surgery—was given to them by his own art, he cannot but feel that the debt might be repaid in some more tangible form than has yet been the case

The demand by the clinical worker that in his special problems he should have at his disposal the full advantage of skilled experimental research, just as it doubtless is, can obviously not be met by deflecting resources now devoted to 'free' research It seems to call for establishments specially directed to the purpose and staffed in part by those whose ultimate interests are likely to be in some branch of the practical art, but who by serving an apprenticeship in experimental science would contribute to the advancement of practical medicine directly by working on its problems and indirectly by infiltrating its ranks with the scientifically trained In a remote way, the same interests, as well as those of the whole of human biology, are being served by that re discovery of man which is now so happily at work in the physiological and pathological fields It is earnestly to be hoped that this process will continue, for by bringing clinical and scientific workers together it will help the experimental sciences in their not always successful struggle against orthodox rigidity, and will help the ancient practical art of medicine in its difficult transformation into an applied science

The Anthropology of Africa

Descriptive Sociology or Groups of Sociological Facts classified and arranged by Herbert Spencer Division 1, No 4, Part 2 A *African Races (Pygmies, Bantu, Equatorial Hybrid Tribes, Sudanic Peoples, Nilotics, Nilo-Hamitics, Fulani, Khoisan)* Compiled and abstracted upon the Plan organized by Herbert Spencer by E Torday A re issue of the Volume originally compiled by Dr David Duncan, entirely re written Issued by Mr Spencer's Trustees (T W Hill, Editor) Pp vii + 385 (London Williams and Norgate, Ltd, 1930) 105*s* net

ONE of the most telling symptoms of vitality in science is the fruitfulness of its practical applications Anthropology, the science of man, has so far kept almost completely aloof from any direct concern in human affairs, as sublime an example of sterility beautiful as the theory of numbers But this is an anomalous condition, and at present public interest as well as political conscience are moving towards a better understanding of the governed races so that they might be better governed

The centre of colonial studies at Oxford, Rhodes House, the International Institute for the Study of African Languages and Cultures, with its principal seat in London, developments at various universities in Great Britain, and such valuable literary contributions as Buell's "Native Problem in Africa", are all signs of this gathering interest

It is only fair that an anthropologist, specially keen about the practical applications of his science, should pay tribute to NATURE for the part it has taken in the movement of humanising anthropology and making it more efficient If anthropology ever becomes an acknowledged force in colonial affairs and receives the full academic recognition which is its due, this will be, to a considerable extent, thanks to the good offices of NATURE At present it is well to put on record that there is but one full time chair of anthropology in the British Isles, the teaching of colonial cadets is not carried out at all in the University of London, where this chair exists, and in those universities where the colonial probationers are trained, anthropology is an optional subject and is confined to what must be a ridiculously inadequate smattering of twenty hours in all This, of course, is negligible, especially if we remember that in other countries, with a colonial tradition as long as that of Holland or France or as short as that of Belgium, from three to five years are required for the special training of future administrators This does not mean to say that an anthropologically trained Belgian administrator has shown himself so far to be better than an untrained Britisher, but that the educated British official would probably be the best of all

The present volume, Mr E Torday's "African Races", brings these reflections to the reader's mind The book deals with Africa, which is by far the most important continent as regards colonial problems, and it is written by a scholar of international reputation Mr Emil Torday is at once a pioneer field-worker, a man of full academic qualifications, though without formal academic claims, and one of the supporters of what is now known as the 'functional school of anthropology', a school which has been foremost in the application of anthropological theory to practical affairs

The functional school explains institutions, customs, and beliefs, not by their antecedents but by the part which they play as living forces within a living culture Functional anthropology consists in new methods and a body of principles which have arisen out of field-work, and which,

on the other hand, are largely inspired by the need for practical applications Modern field-work, done by trained specialists with a good knowledge of native languages and over periods of prolonged residence, has forced us to recognise that whereas it is easy to collect a body of formulæ as to what natives are supposed to do, it is difficult to describe how ideas, customs, and institutions actually work in tribal life The dynamic study of a primitive society reveals that human culture is a very complex type of reality, subject to scientific laws of its own The discovery of the laws of cultural process and of the functional relation between its various aspects and elements is the main field of functional theory

A theory giving clear insight into the nature of culture is indispensable for anyone who sets out to make observations on a hitherto unrecorded type of human society No student of exact science or of biology would dream of sending a plumber or a bookmaker or a lady typist into the laboratory and of relying upon his or her amateur observations Experiments done without theoretical preparation or knowledge of the problems would, as a matter of course, be regarded as worthless in physics, chemistry, or biology Yet in anthropology we have so far been forced to rely on amateur observations, often given without any description of the method and the apparatus by means of which they were made

Worse than that when trained specialists recently started to collect their own material in Africa, Oceania, or the South American jungle, they had no empirical theory as to the nature of primitive culture, that is, of the reality which they were setting out to observe What they were given were hypothetical speculations of the retrospective schools, the evolutionists and the diffusionists But the theories of origin or of historical migrations transplant us in their explanatory setting into a dim past—from six to sixty thousand years back The observer, as often as not a partisan of one theory or another, had his mind turned backwards, riveted on hypotheses and conjectures which made him see the present through the haze of the past, which made him focus on details and elements significant not in their actual context and in their mutual relations, but as relics of something which was no more and, except in speculation, had perhaps never existed

Functional anthropology aims at the reproduction of the native point of view and the native perspective combined with sociological knowledge of what is essential and vital in human institutions. The details of daily life, for example, the organisation of the household and the family, the type of economic activities, the sanctions of law and custom, which so far have received but little attention, have come to be, in functional research, of primary importance All that really matters to the native, all that really serves to maintain order and integrity in a primitive culture and primitive society, is selected as the main object for anthropological study It is clear that such a reorientation of field work and theory al[illegible] by the criteria of dynamic relevancy brings functional anthropology immediately into touch with practical concerns

Mr Emil Torday is one of the pioneer minds in this new school His field-work, carried out under ideal conditions, that is, during prolonged residence and through the medium of the vernacular, gives us a full picture of tribal life and is never confined to curious and sensational details

In the present computation of facts, Mr Torday proceeds throughout according to the rules of the functional method, that is, by the criteria of relevancy, function, and social value As is the case in all scientific work, it is the selection which really matters, the emphasis on the relevant, the subordination of the accidental In doing this, Mr Torday had an ardous task, for he was severely handicapped by the exacting conditions of the Herbert Spencer Trust, which lays down the subject matter, the headings, the order, as well as the relation between the geographical and the systematic divisions of the material By the introduction of a concise but extremely helpful table of contents, by adding illuminating subheadings and cross-references, Mr Torday was able to palliate some of the inadequacies of the original Herbert Spencer plan By adding copious critical notes to the quotations, Mr Torday places the data in the right perspective, correlates the observations of the various authors, and establishes the functional aspect of the material at his disposal But it seems necessary once more to urge the Trustees, who, I know, are fully aware of the inadequacies of the present plan, that energetic steps should be taken to a complete revision of the bequest

As it stands, the book is a most tantalising production The field-worker, the administrator, the missionary, and even the traveller could use [illegible] with the greatest profit on the spot in Africa But how is he to carry a volume 1½ ft by 1 ft and some twelve pounds in weight unless a special means of

transport and a scaffolding or lectern be provided to read it? It would be necessary in the wilds of Africa to charter an elephant, a camel, or at least an ass or a Ford lorry in order to make it the 'handy guide-book of Africa', to which title it has full claim Had it been published in a portable size, and had it been allowed to Mr Torday to divide the material geographically, this book might have consisted of several volumes, each relevant to one particular area, each portable, and the whole of the greatest practical utility Again, it is a thousand pities that a writer of Mr Torday's eminence should be compelled to make a mere compilation with comments and cross-references only, and limit his original contribution to an all too short preface This, written with the weight, attractiveness, and convincing clarity for which Mr Torday is well known, among others through his "Causeries Congolaises", contains a brief exposition of the functional point of view, illuminating sidelines on the nature of African races, especially of the Hamites, Pygmies, and the Bantu, and it gives us also a summary of the enormous advances attained by African studies since 1875, when the first version of "African Races" had been contributed as a volume of Herbert Spencer's "Descriptive Sociology"

The excellent map contributed by Miss Ursula Torday will be a boon, not only in the use of this volume, but also for African anthropology in general B MALINOWSKI

Conduction in Electrolytes

(1) *Electrolytic Conduction* By Prof F H Newman Pp xii+441 (London Chapman and Hall, Ltd, 1930) 25s net

(2) *The Electrochemistry of Solutions* By Dr S Glasstone Pp x+476 (London Methuen and Co, Ltd, 1930) 21s net

THE study of physical science is extraordinarily fascinating nowadays We see much farther, even if we see a little less clearly than our grandparents saw—or thought that they saw Our most innocent experiments and observations are weighted with philosophical and theological implications of cosmic importance We make measurements that are each year more and more exact, and find ourselves committed to a principle of indeterminacy We read of a quantum mechanics which, in a praiseworthy endeavour to escape from those mechanical pictures which are based on an extrapolation of our large-scale experiences, employs a symbolism in which the exact nature of the symbols employed remains unspecified *Naturam expellas furca* , and the heroic exponents of these latest symbolic methods—latest, though not novel, for are they not closely related to the ideals of Kirchhoff?—find themselves compelled, willy-nilly, to use terms and concepts based on those of our everyday experience

It is all very interesting, but it is none the less pleasant to find that there are corners in the realm of science where a consistent scheme can be built up on a basis of 'ordinary' space-time perceptions, where the principle of indeterminacy is not, where the motion of ions through a viscous fluid is determined (perhaps a little doubtfully) by Stokes's law, and where a modern theory of strong electrolytes may be based on nothing more unusual than Boltzmann's principle and Poisson's equation The theory of electrolytic conduction and the technique of the measurements associated therewith are in a state sufficiently stable to make it worth while to attempt an assessment of the condition of this important branch of physical science, and the two volumes here reviewed cover the topics of greatest importance in a very comprehensive and systematic manner

(1) Prof Newman's book is written by a teacher who has a lively and sympathetic appreciation of the difficulties which confront an intelligent and conscientious reader The work, which will provide stimulating reading for a university student of honours grade, builds up the subject from the very elements In a laudable desire to give the reader all that he needs between the covers of a single volume, the author leads off with a condensed but very clear sketch of thermodynamic principles, which includes a discussion of the usual relations between osmotic pressure and boiling or freezing points, of thermodynamic potential and free energy, of the Nernst heat theorem, the phase rule, and the Gibbs adsorption equation Condensation has its dangers, however, and, admirable though the summary is, we confess to a dislike of the dictum that $\Sigma\,(dQ/T) < 0$ for an irreversible cycle, while the unadorned statement that, if δQ is the amount of heat passing (by conduction) from a body at a temperature T_1 to a body at a temperature T_2, then the net gain of entropy is $(\delta Q/T_2) - (\delta Q/T_1)$, raises more doubts than it resolves

The main body of the book covers a wide field Starting from the fundamental Arrhenius concept of spontaneous dissociation, the author develops a general view of the problem of electrolytic conductance, and then proceeds to treat in detail of ionic migration, ionic equilibria, cells and electro-

motive force, electro capillarity, polarisation, the measurement of electrolytic resistance, theories of electrolytic solution, and technical applications A reasonably full bibliography accompanies each chapter, and a reader who has used the book intelligently will find its perusal a very useful preparation for an attack on research problems in electrolysis

It has been the reviewer's experience that one branch of experimental work, and that branch one of fundamental importance, has been shrouded in a quite unnecessary mystery We refer to the measurement of electrolytic resistance, where it is not uncommon to find an experimenter capable of, and actually making, very precise determinations with but a cloudy idea of the exact conditions under which inductance and capacity effects are balanced out, and of the relation between impedance and resistance Prof Newman's chapter on electrolytic resistance measurement, wherein he discusses very clearly and straightforwardly the application of the ordinary alternating current equations to the bridge system involved, should do useful service in dispelling this mystery His descriptions and diagrams of the experimental methods used, including that of a valve oscillator as a source of alternating current, are clear and up to date But we note that he begins the chapter with the remark that "as shown by Kohlrausch

$$E_0 \sin pt = Ri + P\int i dt",$$

developing the theory from this equation Prof Newman has been so thorough, within the limits of his four hundred and forty pages, in his treatment of fundamentals that it seems a pity that he should pass over this important expression without more detailed discussion, and we trust that in a later edition of his work he will remedy this omission

The chapter on theories of electrolysis gives a very useful resumé of the various theories of strong and of weak electrolytes, and the exposition of the Debye Hückel theory and of the subsequent developments by Onsager is very clearly put

(2) The bias of Dr Glasstone's treatise is indicated by its title being, as compared with Prof Newman's book, considerably fuller in its discussion of those topics which are usually associated with an advanced course of physical chemistry He, again, starts from the fundamentals, and while his discussion of the methods and theory of resistance measurements is a little more restricted than that of Prof Newman, he gives us a more detailed treatment of topics such as overvoltage, depolarisation, the theory of amphoteric electrolytes, and the theory of reversible cells, which last topic is treated in very considerable detail

In discussing the elementary theory of ionic migration and concentration changes, Dr Glasstone makes use of the usual picture of chains of oppositely moving positive and negative ions, it would add much to the interest of his treatment were he to give some reference to the critical paper dealing with this method of illustrating the process which was read by Prof S W J Smith some years ago before the Physical Society (*Proceedings of the Physical Society*, **28**, 148, 1916) Neither book contains a reference to the simple and elegant algebraic treatment of this problem which was advanced by Larmor in his Adams prize essay on "Æther and Matter" (p 289, Appendix C, on Electrolysis)

The choice of topics lies entirely within the author's province, but the reviewer feels that it would add considerably to the value of an interesting treatise were Dr Glasstone to consider in some little detail Smith's very interesting experiments on the potential difference developed at the interface between two electrolytic solutions, and on the related problems of the asymmetric nature of the surface tension potential curve for a capillary electrometer

The two books are in some measure complementary and, taken together, give a conspectus of results and theories in this department of physical science which will be invaluable to physicists and to physical chemists, and will provide the research student with a mine of indispensable information

ALLAN FERGUSON

The Passing of Woad

The Woad Plant and its Dye By the late Dr Jamieson B Hurry Pp xxviii + 328 + 17 plates (London Oxford University Press, 1930) 21s net

BRITAIN has always been fortunate in its amateur scientific workers men, by no means real amateurs in science, who find delight in the intervals of a busy life in following seriously some definite line of investigation Of this category was the late Dr Hurry, who, in the midst of a very crowded career as a medical practitioner in Reading, was yet able to study systematically and as a most careful monographer to render signal service to knowledge Quite why he chose to tell the story of the woad plant is not revealed, but he had a lifelong interest in economic botany and at his home he established an educational garden and

museum The woad plant and its famous blue dye are studied from an international point of view, and the book aims both at giving a comprehensive account of the industry in several countries and emphasising so many other points of view that it becomes a contribution to our knowledge of the social and industrial life of the Middle Ages

Successive chapters deal with the cultivation and manufacture of woad, its use in the fermentation vat, the extraction of the glucoside, indican, succeeded by an historical account of the industry in Britain, France, Germany, and Italy Economic questions have next place, followed by a full account of the old world lore relating to the place of woad in herbals and in therapeutics Final sections are devoted to the protection by legislation and the death of the woad industry

Dr Hurry's name is a sufficient guarantee of the thoroughness and careful attention to detail which characterise the book, withal it is attractive reading for those who appreciate broad and liberal treatment of what might appear to be a specialist subject There have been two crises in the woad industry The first was when in the seventeenth century trade routes were opened up to India and the dye, extracted from material made in Europe, was threatened by imports from that country The Dutch East India Company, formed in 1631, in course of time imported sufficient indigo into Holland to supply the needs of the whole world At much the same time, logwood and Brazil wood also appeared on the scene, so there is little wonder a strenuous campaign took place to secure protective legislation in favour of the indigenous dye, the woad merchants were so successful as to induce various governments to prohibit entirely the use of exotic indigo Even the death penalty threatened those who infringed the protective laws then passed As is well known, protection failed, the superiority and the cheapness of exotic indigo could not be gainsaid In Germany, too, the Thirty Years' War destroyed the woad fields and the villages of Thuringia

The second crisis was due to the advance of synthetical organic chemistry Synthetic indigo was first made in the laboratory, starting out from aniline, and then after some years of persistent effort, at the time regarded as a model piece of industrial research, and the expenditure of very large sums of money its economical industrial production was achieved shortly before 1900 A fierce struggle between the natural and the artificial product ensued, fought with the utmost energy and often bitterness on both sides Indigo planting in India became no longer profitable, and though scientific methods were introduced, yields increased, costs reduced, the natural indigo could scarcely hold its own With the advent of the World War, first England and then the United States became makers of synthetic indigo, and at its conclusion joined battle with Germany primarily to secure the Chinese market Costs were drastically and suddenly reduced so that the natural product received its death blow overnight To day indigo is cheap enough, but it is doubtful if the makers profit the gain goes to the Chinese

The economic history of woad is matched in interest by its botanical and by its chemical significance and by the legends which surround it The chemist has synthesised in his laboratory both indigo the dye, indican the glucoside, and also bromoindigo and its glucoside "the purple of the ancients", the Tyrian purple of the Roman emperors, who obtained it from the tongue of a deep water mollusc Indigo was first brought to Rome about A D 50, so that the purple is of older date than the blue

The carpets at the Persian Exhibition in London have taught us anew of the wonderful and permanent colours obtained from plants—woad, madder, Persian berries, and many others should be grown at Kew and elsewhere suitably labelled to remind us of the contents of Nature's paint-box

Our Bookshelf

Das Tierreich eine Zusammenstellung und Kennzeichnung der rezenten Tierformen Gegründet von der Deutschen Zoologischen Gesellschaft Im Auftrage der Preussischen Akademie der Wissenschaften zu Berlin Lief 52 *Myriapoda* 1 *Geophilomorpha* Bearbeitet von Dr Graf Attems Pp xxiii + 388 60 gold marks Lief 53 *Crustacea Copepoda* 2 *Cyclopoida Gnathostoma* Bearbeitet von F Kiefer Pp xvi + 102 n p (Berlin und Leipzig Walter de Gruyter und Co, 1929)

Two further parts of this great work have recently appeared, in each of which the literature of the respective subjects up to the beginning of 1929 has been considered

(1) Dr Graf Attems prefaces the systematic part of his volume by an account of the external features of the Chilopoda and of the epidermis and its glands, including the unicellular ventral glands of the Geophilids, each cell of which is enveloped by a network of striated muscle fibrils There is a brief reference to the sense organs The characters of the order Geophilomorpha are stated, the features of systematic importance are described, and a table is given for the separation of the ten families The

subsequent treatment follows the usual lines, with which those who have used the previous parts are familiar—a definition of each family, a key to its genera, a definition of each genus, and keys for the constituent species and subspecies 128 recognised genera and 452 species are described, but there remain 17 genera and 190 species the position of which is uncertain, owing to insufficient diagnosis by their respective authors An appendix is devoted to an account of about a score of species, for the most part described after the preparation of the body of the work

(2) The first suborder of the Copepoda—the Calanoida—formed the subject of the sixth volume (1898) of this work The present author briefly states the characters of the second suborder, the Cyclopoida, and its three sections, the Gnathostoma, Siphonostoma, and Pœcilostoma The first of these sections forms the subject of this part Three families with 18 genera and 192 definite species are considered About 50 additional species are of uncertain position The author appears to have overlooked two new species of *Cyclops* described by G S Brady in 1910 This part will be of use not only to marine and freshwater zoologists, but also to helminthologists who desire to determine the species of *Cyclops* which they find acting as intermediate hosts—for example, for the broad tape worm of man and for the guinea-worm

Each part has a systematic index and *nomenclator generum et subgenerum*

A Newton among Poets Shelley's Use of Science in Prometheus Unbound By Prof Carl Garbo Pp xiv + 208 (Chapel Hill, N C University of North Carolina Press, London Oxford University Press, 1930) 13s 6d net

THIS valuable and interesting book is another proof of the breadth of mind with which American professors so often pursue their studies The bulk of the book is taken up by a summary of the scientific theories of Shelley's time, and especially of the work of Humphry Davy and the poems of Erasmus Darwin which had appeared just before Shelley wrote his "Queen Mab" and "Prometheus Unbound" The result of applying these to the elucidation of the poems, and especially of the "Prometheus", is highly curious and instructive It was well known before that Shelley was passionately interested in science and fond of experiments in chemistry and electricity His father is reported to have once returned a book on chemistry which Percy had borrowed, because it was "a forbidden thing at Eton", and Prof Whitehead, in "Science and the Modern World", quotes a notable example of Shelley's power of visualising an astronomical relation But no one before Prof Garbo has gone through the "Prometheus" thoroughly with this thought in mind, and his conclusions generally command assent It is obvious that Shelley's mind was steeped with the science of the time, and many of the most beautiful and transcendent passages are chemical or electrical experiments transfigured by poetic genius One might almost think that Shelley was consciously trying to carry out the ideal of the poet of the future which Wordsworth sketches in the famous preface to the second edition of the "Lyrical Ballads" (1800) "The remotest discoveries of the Chemist, the Botanist or Mineralogist will be as proper objects of the poet's art as any upon which it can be employed And what is now called science, thus familiarised to men, shall put on, as it were, a form of flesh and blood, the Poet lending his divine spirit to aid the transformation" We commend a consideration of this further connexion to Prof Garbo for his second edition F S M

Life and Evolution an Introduction to General Biology By Prof S J Holmes Pp v + 449 (London A and C Black, Ltd, 1931) 12s 6d net

AN elementary text book of biology, written by the professor of zoology in the University of California, and designed, not so much to prepare students for further specialisation in a branch of biology, as to give a general view of biological problems to those whose main energies are going to be directed in other fields The book is comprehensive in scope, ranging from protoplasm and the cell theory, through the different forms of plant and animal life, to heredity, evolution, and eugenics

Prof Holmes's book was originally published in the United States, and that edition was reviewed in NATURE of June 5, 1926 For the British edition, now before us, a number of minor revisions have been made in the text, and about twenty of the illustrations have been changed or improved The most important revision, however, is the anglicising of the spelling throughout and the complete remodelling of the bibliography at the end of each chapter for the benefit of British readers Otherwise the book is identical with that already published in America

Air Ministry Meteorological Office The Meteorological Glossary (M O 225II) Second edition, entirely rewritten In continuation of *The Weather Map* Published by the Authority of the Meteorological Committee Pp 233 + 12 plates (London H M Stationery Office, 1930) 4s 6d net

THIS glossary shows signs of very thorough revision and is full of information in a compact and handy form, thereby fulfiling some of the functions of a text book There are charts and numerous diagrams, and a good deal of statistical and descriptive information about the climate of Great Britain is given under several of the headings, particularly in the section on rainfall It is difficult to think of any term in any way connected with meteorology that is not given a place in the bold type headings, and the names equivalent to the English of a number of meteorological phenomena are given at the end of the volume in several languages, at the request of the International Meteorological Committee References in the articles to matters dealt with in other parts of the glossary conveniently appear in italics

Stellar Structure

ZANSTRA'S recent determination of the temperatures of the *O* stars in planetary nebulæ [1] makes it appear extremely likely that these stars are all generically in the 'white dwarf' class, with mean densities far above anything known on the earth. He has found temperatures between 30,000° and 100,000° for about twenty of these objects, and yet their luminosities are comparatively small. For a fairly typical nebular nucleus we may assume a photographic magnitude of 12.5 with a parallax of 0.002″, making the absolute magnitude +4, or about eight magnitudes fainter than typical galactic *O* stars. It is, of course, true that the luminous *efficiency* falls off with rising temperature in this range, but an increase in temperature at constant radius must always involve an increase in brightness, proportional, even in the farthest part of the Rayleigh–Jeans region, to at least the first power of the temperature. Thus these stars must be of very small radius.

Zanstra obtains his figures from the difference between the measured brightness of the star and that of the nebula, which latter is assumed to be excited by the main (Schumann region) radiation of the star, and to convert all of it to long wave-lengths. The nebula thus performs the correction from visual to bolometric magnitude for us, as it were; if it does not do so completely, the star must be still hotter than is calculated. The correction is found to vary between 2 and 7 or 7.5 magnitudes; in an average case it would be about 5 magnitudes, and the temperature would be rather more than 55,000°. Such a star would then be about 5.9 magnitudes brighter than the sun bolometrically, with ten times its surface temperature; this means a radius 1/43 of the sun's, so that even with the sun's mass its density would be more than 100,000 gm./c.c.

The masses are, however, certainly greater. In a typical planetary, the line of sight rotational velocity can be taken as 5 km./sec. at 6″ from the nucleus, and with a parallax of 0.002″ this gives a mass 80 times the sun's.[2] If the gas is partly supported by radiation pressure, or if the axis is inclined to the line of sight, the figure comes out even greater. This may be set off against the allowance for the mass of the nebular envelope. The data indicate, therefore, a mean density of 10^6 or 10^7 gm./c.c., which is greater than has even been suggested for any other bodies, and points conclusively to a degenerate state of matter.

These bodies appear to be at the upper end of a sequence of 'white' dwarfs, as may be seen from the following summary:

	M_v	Spectrum
Planetary nuclei	+4	*O*
o Ceti *B*	6	*B*8e
o^2 Eridani *B*	11	*A*0
Sirius *B*	10	*A*5
van Maanen's star	14.5	*F*
Wolf 489	13	*G*

It looks as if this sequence were roughly parallel to the main sequence, probably separated from it by a sparsely populated band, and with considerable scattering within it; at least, the general trend is evident, and the reason why no red stars of the 'collapsed' type have been discovered is of course obvious.

There are grave difficulties in the assumption that the source of energy within these white dwarfs is of the same nature as that within giants and main sequence stars, so that it seems worth while to point out that they have no very obvious need for a subatomic source at all. Just before degeneracy sets in, the internal temperatures must be of the order of at least 50 times those of a main sequence star built on the 'diffuse' model, or fully 10^9 degrees; Milne's calculation for the companion of Sirius [3] indicates a central temperature not exceeding (but apparently approaching) 3×10^9 degrees. The rate of radiation of such a star is only about 1/100 of that of the sun, or say one calorie per gram in 60 years; taking the specific heat as 3 (when the gas is still on the edge of degeneracy) we see that there is an internal store of heat sufficient for radiation at the white dwarf rate for something of the order of 10^{11} years. Of course, the very fact that the star is about to become degenerate means that not nearly all the kinetic energy of the nuclei and electrons will actually be available for radiation; much of it must remain as zero point energy permanently in the star. But against this we must set the further energy to be obtained from such contraction as is still possible; at these small radii this energy is large. On the whole, then, the life of a white dwarf comes out, without any subatomic sources, entirely comparable with that of any star that derives its energy from the transmutation of hydrogen into heavier elements.

If the available subatomic energy of a main sequence star is exhaustible, the period spent in the main sequence will be followed by one of gravitational contraction; in the early stages this will be rapid, because the radius is large, and because at least half the energy gained will go into heating the interior of the star; in the late stages, the internal temperature will actually be falling, gravitational contraction will be very effective (if degeneracy is not too marked) and the rate of radiation will have become small. The fairly late stages will therefore be passed through very much more slowly than the early ones, and there will be a marked statistical concentration of the stars at radii perhaps two or three times the minimum figures calculated by Milne for a fully degenerate star. The minimum values are roughly $M^{-1/3}/80$ times the sun's radius, for a star of mass M times that of the sun, and where the masses are known the radii are all of about the anticipated size. Particularly high densities are clearly to be expected for the *O* stars. In van Maanen's star, with a radius of 0.007 times the sun, it is tempting to suppose we have a massive star in a very late stage indeed; if Milne's formula is applicable, the mass must be at least 8 times the sun, which would mean an Einstein shift corresponding to at least 700 km./sec. This could easily be tested by observation.

It is worth remarking that in a century or less the true radial velocity of a star of such large proper motion and parallax as this could be found from the second order term in the proper motion; the relativity effect, even if much smaller than 700 km./sec., could then be fairly definitely determined.

However that may be, we have now fairly good evidence that stars of all masses can 'die'; this does not prove that transmutation rather than annihilation of matter is the source of stellar energy, but it clearly favours it. For Milne's theory leads to the conclusion that a mainly or nearly degenerate star will have a central temperature that may be much less than, but cannot be greater than $3.9 \times 10^9 M^{5/6}$, and this seems inadequate to stimulate a source of energy that was

not active in the main sequence, especially if all stars have dense hot cores, as Milne believes. Thus the very latest stages of degeneracy, where the specific heat is small and contraction difficult, must be run through rapidly, and the total duration of the white dwarf stage probably is not much greater than we have already calculated. The probable relative abundance of white dwarfs is then somewhat difficult to reconcile with a time scale of 10^{13} or 10^{14} years, but fits well with the transmutation theory time scale.

The view that the nuclei of planetary nebulæ are 'white dwarfs' has, we now find, already been propounded by Jeans in "The Universe Around Us", pp. 309-311. That we had both failed to notice this can be excused, if at all, only by the great popularity of the publication in which the theory was announced, but we sincerely regret the oversight. In the application of this result we differ from Jeans, since he tentatively placed these stars at the beginning of stellar evolution, while we place them, with the other white dwarfs, at the end.

Emission Bands in the Mercury Spectrum under Low Excitation

SOME years ago I found a long series of diffuse bands from λ2943 to λ2614 in the absorption spectrum of a long column of mercury vapour.[1] The same series was found independently and about the same time by Mohler and Moore.

Up to the present, these bands have never been obtained in emission. I now find that when mercury vapour is fluorescing under the iron arc (excitation from λ2650 to λ2537) these bands are emitted, and in much greater intensity if the vapour is superheated. The continuous emission from about λ2950 to λ3600 (maximum at λ3300) is also much increased by superheating, while the green visual fluorescence is extinguished. So far as my experiments go, the emission bands seem to be in close relation to this continuous emission at λ3300, though I am not prepared at present to say that this is invariably the case. Much longer exposures are required for the bands than for λ3300, but when such exposures are given, the bands appear as a kind of prolongation of the continuous emission. The continuous region, it is to be noted, is at the less refrangible end of the band series, where the band spacing is widest, and not beyond the convergence point, and this continuous region, unlike the bands, is not known in absorption. It will be important to examine the absorption of the superheated vapour.

The remarkable phenomena connected with the band spectra of mercury, and the long time of duration of the emission, are very complicated, and I think that speculation has rather outrun our knowledge of the facts, which is by no means adequate. It is my aim to find out as much as possible under conditions of low frequency excitation, less than the frequency of the atomic resonance line λ2537. These conditions should reduce the problem to its simplest form.

Proton and Electron

THE ratio of the mass of the proton, M_P, to that of the electron, m_e, is a pure number which is likely to be of considerable importance in physical theory. In a recent letter, Dr. W. N. Bond[1] has deduced for this ratio the value $1846 \cdot 5_7 \pm 0 \cdot 4_8$ with a probable error which should be accurate to about ten per cent. This is very close to the 'deflection' value of Birge,[2] $1846 \cdot 61 \pm 2$, but larger than the 'spectroscopic' value $1838 \cdot 26 \pm 1$.

The suggestion of A. P. Mathews that

$$\frac{M_P}{m_e} = \left(\frac{135}{\pi}\right)^2 = 1846 \cdot 58$$

gives remarkable numerical concordance with Bond's estimate, but it seems, at present, to have no theoretical significance.

As Dr. Bond has pointed out, the relation proposed by Rojansky[3] and also by Eddington,[4] which gives

$$\frac{M_P}{m_e} = \frac{(136)^2}{10} = 1849 \cdot 6,$$

is not in good agreement with recent experimental determinations.

The same objection applies to Witmer's hypothesis[5] that

$$\frac{M_P}{m_e} = (43)^2 = 1849.$$

I venture to add one more suggestion to the many already made as to the ratio of these two masses. Fürth[6] has obtained a remarkable relation involving the constant of gravitation, G, and the mass of the 'neutron' which he regards as formed by the combination of a positive and negative electron. Assuming this mass to be the same as that of the hydrogen atom, M_H, his relation may be written in the simplified form $2\hbar c/GM_H^2 = (16)^{32}$, where $\hbar = h/2\pi$. This gives good agreement with experimental results.

The power of 16 which occurs in Fürth's relation is introduced in considering the number of arrangements in a 16-dimensional continuum as in Eddington's theory, which requires 16 parameters for the complete determination of an electron. For an electron Fürth finds a total of 16^{16} possible arrangements and for a 'neutron' 16^{32} distinct possibilities. His formula suggested to me that the ratio of the masses of proton and electron might be of the form

$$\frac{M_P}{m_e} = \left(\frac{16}{10}\right)^{16} = 1844 \cdot 68.$$

Here again, the number 16 represents the number of parameters or 'degrees of freedom' which, according to Proca,[7] are characteristic of an electron. These Proca classifies as 4 co-ordinates, 4 moments, 3 components of magnetic moment, 3 components of electric moment, the mass, and the de Broglie wave-length. The presence of the integer 10 in the above relation may be explained by assuming that, of the 16 degrees of freedom associated with an electron, 6 are suppressed or 'frozen' in the case of the positive electron. It is natural to suppose that these are the three components of the electric moment and the three components of the magnetic moment, all of which are here regarded as having some real physical meaning for the negative electron. Perhaps the proton, as contrasted with the negative electron, is simply 'a hole in the ether' without electric or magnetic moment. This hypothesis reverses the rôles assigned to these two entities in 1913 by S. B. McLaren, who assumed that the positive electron was the magneton.

It is with some hesitation that I put forward this tentative suggestion, partly because the theory of

Furth seems to be based on somewhat uncertain assumptions, and also because the value suggested for the ratio of the masses is not in exact agreement with either the 'deflection' or the 'spectroscopic' values

Low Altitude Aurora

Mr Axel Corlin[1] has described an observation which has convinced him that the aurora can appear under the clouds I have also observed a similar phenomenon, but in circumstances which made it possible for me to convince myself that the whole effect was an illusion and that the aurora was above and not below the clouds

In my opinion it would be unfortunate if Mr Corlin's account should be accepted as good evidence that an aurora can appear 'only a few thousand metres above the ground' especially in view of Prof Chapman's important article[2] in which he practically accepts the evidence for low aurora

The essentials of Mr Corlin's account are as follows

"In the afternoon of Nov 16 1929 during my stay in Abisko in northern Sweden (N lat 68 21′) I observed a rather intensive auroral ray of about 10° apparent length and about ½ apparent breadth in the west south west *below a completely cloudy sky*"

"The clouds, apparently situated behind the ray, were of stratiform alto cumulus type and consisted of apparently thin and thick strata The ray began in or in front of a thin stratum, crossed over a thick (more dark) stratum *without appearing less intense here* and vanished in or in front of the next thin stratum In the east, similar clouds covered almost completely the sky and *also the full moon* which was visible only a few times between the clouds Examining carefully the facts mentioned above in italics, I could not escape the conclusion that the auroral ray must be *below the clouds*, that is at only a few thousand metres above the ground"

My experience is recorded in a paper, "Atmospheric Electricity in High Latitudes",[3] which describes observations made at Karasjok, Norway (69 17′ N, 25° 35′ E), during twelve months, October 1903–September 1904 I wrote, p 92

"It has long been a matter of controversy as to whether the aurora ever extends into the lower regions of the atmosphere Several observers positively affirm that they have seen it quite close to the ground This may be due to an optical illusion, one evening I was, for a considerable time, in doubt as to whether the aurora was really under the clouds or not All over the sky were detached clouds, the clouds and spaces between them being of about the same size and shape Right across the sky a long narrow aurora beam stretched, showing bright and dark patches owing to the clouds It looked exactly as if the aurora beam ran along under the clouds, brightly illuminating the patches of cloud which it met In reality the bright patches were the openings and not the clouds It took me a long time to make quite certain of this, and it was only by at last seeing a star in the middle of a bright patch that I could be quite certain"

It is clear that these two experiences were practically identical, and there can be little doubt that what Mr Corlin considered to be thicker parts in the cloud covering were really breaks in the cloud through which the dark sky could be seen In his case the illusion was probably enhanced by the clouds near the moon showing dark centres

Although it is now twenty seven years since I made my observations, I clearly recollect the difficulty I had in deciding what was cloud and what was clear sky The illusion was most convincing, and if I had not been able to see the stars in the patches which appeared to me to be illuminated cloud I should have come to the same conclusion as Mr Corlin

The Molecular Weights of Proteins

One of the most satisfactory features of recent advances in the X ray analysis of compounds of high molecular weight has been the degree of co ordination between the efforts of the structure analyst and those of the chemist Especially is this true in the case of investigations of the structure of cellulose and its derivatives The question of protein structure, however appears to bring in its train problems of quite another order of complexity, and it does not seem to be at all clear what is connoted by the phrase 'molecular weights of proteins' Such X ray photographs of fibrous proteins as have been obtained point to the periodic repetition of comparatively simple units with imperfect or variable side linkages In the quest for chemical data to correlate with these results the crystallographer is at once brought up against the remarkable observations of Svedberg, that there are groups of soluble proteins of 'molecular weights' which are simple multiples of 34,500 The present situation is most simply described by quotations from two recent letters[1 2] to Nature

1 "The two most striking demonstrations in recent years of such uniformity are afforded by Svedberg's brilliant application of the ultracentrifuge to determine the particle mass of soluble proteins, classes of 'molecular weight' 1, 2 3, and 6 times the common factor 34,500 being distinguished, and Gorter and Grendel's demonstration that under appropriate conditions soluble proteins exhibit the phenomenon of surface spreading on liquids and that all occupy the same surface area irrespective of particle mass (1 2, 3, or 6 times 34,500) Using Svedberg's common factor 34 500 for the basis of their calculations, the Dutch workers obtain a value for the radius of the unit particle (22 5 A) identical with that determined by Svedberg experimentally"

2 "Three determinations of the sedimentation equilibrium of insulin at a pH of 6 7–6 8 gave as a mean value for the molecular weight 35 100, which within the limits of experimental error is the same as that for egg albumin, 34,500, and for Bence Jones protein, 35,000 The sedimentation equilibrium determinations show that crystalline insulin is homogeneous with regard to molecular weight, that is, the molecules in the sample studied were all of the same weight"

If now we consider this problem from the purely crystallographic point of view—and it has been demonstrated that proteins under certain conditions can give rise to X ray crystal photographs—the numbers 1, 2, 3, and 6 immediately invite attention as being possible numbers of 'molecules' which can go to form a unit of pattern The suggestion thus

arises that, provided we can explain the occurrence of the weight 34,500, the rest may be merely another aspect of that grouping of molecules which is called crystalline But if this is so, we have to account for the non occurrence of the number 4, and the explanation of this gap must be given in terms of some outstanding characteristic of proteins in general

In order to explain the sequence of numbers observed it does not seem necessary to invoke anything more unfamiliar than the ordinary peptide chain, CO NH CHR CO NH CHR , which is built up of a succession of triads of which the CO and NH groups are unsaturated , for if we postulate that the CO and NH groups of neighbouring chains can be linked together by secondary valences, the following simple crystallographic combinations[3] are at once available (Figs 1*a*, 1*b*, 1*c*, 1*d*)

In Fig 1*b*, corresponding to the crystallographic space group C_2^1, the unit of pattern is a pair of chains pointing in opposite directions while the basis of Fig 1*c*, space group C_3^2, is a self contained threefold screw of chains all pointing in the same direction In Fig 1*d* one of the chains has been omitted to avoid confusion, but it will be seen that it is a grouping

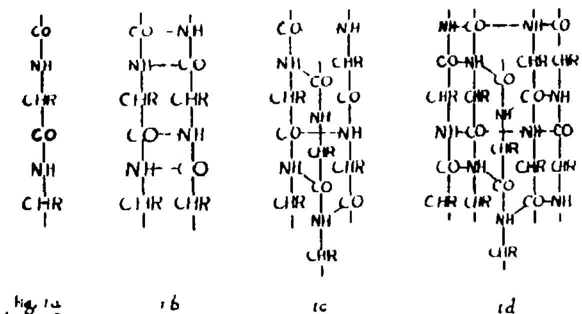

FIG 1

which is a combination of (*b*) and (*c*) based on the space groups D_3^6 and D_3^4, and is also a self contained threefold screw, but this time not of single chains, but of pairs of chains such as are shown in Fig 1*b* All these molecular associations are well defined crystallographic types -the arrangement shown in Fig 1*d*, for example corresponds to the structure of such a common crystal as quartz —which might be expected to undergo reversible dissociation into their constituent units, or sub groups That such a process actually does take place is best illustrated by the words[4] of Svedberg himself —"The protein molecules containing more than one group of weight 34,500 are, as a rule, dissociated into molecules of lower numbers of groups of 34,500 when the *p*H of the solution is raised over a certain value Thus the proteins of weight (6 × 34,500) split up into molecules of 1/2, 1/3, and 1/6 of the original molecule, but never into molecules of 1/4 or 1/5 of the original This is in line with the fact that proteins possessing these latter weights at or near their isoelectric point have not been met with At sufficiently high alkalinity all proteins have the same molecular weight, viz , 34,500 "

The problem embodied in the last sentence still remains for discussion, and we should like to suggest as the interpretation of this, the most fundamental difficulty of all, that the observed constancy of unit molecular weight is simply a case of the vibrational instability of peptide chains when their length exceeds a certain value If we accept the X-ray indications that the fibrous proteins, such as hair[5] and silk,[6] are based on the periodic repetition of comparatively simple units, then the probability of disruptive resonance occuring among the constituents of the peptide chain will continually increase with the length, so that excessively long chains would be liable to spontaneous decomposition into shorter chains We may imagine some such process taking place the laboratory of the living cell as the amino-acids ar laid down in long chains at a surface and consolidated by crystallographic groupings in the manner suggested above, or by intra molecular folding such as has been demonstrated in the case of wool and hair[5] From this point of view, it does not seem likely that the unit molecular weight of proteins is strictly constant—this, too is in agreement with experiment- but there is a strong probability that, given the appropriate conditions, many proteins will be based on a roughly constant weight of peptide chain *

A phenomenon which appears to involve analogous reasoning is the decay of tension at constant length which takes place in stretched hair containing moisture, and which has been investigated by Speakman[7] A large part of this loss of tension is quite permanent,[8] in spite of the fact that the stretched hair still retains its power of recovering at least its original length in water The rate of decay of tension varies with the type of wool or hair and with the nature of the wetting agent, and increases with rise of temperature It is extremely rapid in steam, a short treatment with which permanently alters the load/extension curve, and so loosens the internal structure of the fibre that it may be caused to contract to two thirds of its original length[5]

It is clear, of course, that the wetting agent plays an important part in this permanent destruction of internal tension, but it seems not at all unlikely that vibrational instability also is an essential factor in the process After treatment of stretched hair with steam, the longitudinal swelling of the fibre in water is considerably increased, a fact which, taken in conjunction with the observation that X ray photographs of hair which has been held stretched in water for several weeks show a definite fuzziness of the reflections associated with the length of the peptide chains suggests that the average length of the chains is decreased by sustained tension in the presence of water

We have recently commenced an investigation of the influence of radiations, such as ultra violet light and X rays, on the elastic and other properties of animal hairs, so that in this connexion it is convenient to mention here some remarkable observations which we have made on *unstretched* wool exposed for some sixty hours to the full beam of a Shearer X ray tube (copper anticathode) After this treatment the fibres show many of the properties which are characteristic of wool which has been exposed *in the stretched state* to the action of steam For example, they have the property of contracting in steam by as much as 37 per cent below their unstretched length, and their longitudinal swelling in water after steaming is found to be increased from the 1 per cent of normal wool to as much as 10 per cent This seems to be a clear case of the disruptive action of high-energy quanta on the length and cohesion of peptide chains, and must be closely related to the influence of various radiations on biological activity

* If we assume the essential correctness of the structure proposed,[5] we may make an estimate of the length of peptide chain in animal hairs. The average molecular weight of the chief amino-acids in wool (which are present in roughly equal molecular proportions) is about 121, and three amino acids occupy a length of 5 15 A along the fibre axis The length, corresponding to 34,500 is thus about 500 A It is a striking fact that this is approximately the length which is the minimum possible to give the observed X ray diffraction effects[5] That it is also near the actual length is indicated by the fuzziness which appears in X ray photographs of hairs which have developed pronounced permanent decay of tension

These experiments are being continued and will be reported in detail in due course

The *p*H Stability Region of Insoluble Proteins

BY means of the ultracentrifugal method developed in his laboratory, Svedberg[1] has measured the stability of a number of soluble proteins as a function of the *p*H of the environment Each of the monodisperse proteins was found to have a fairly wide *p*H stability region which included the isoelectric point By means of a totally different technique, we have recently been able to show that insoluble proteins, such as wool keratin, are no exception to the above

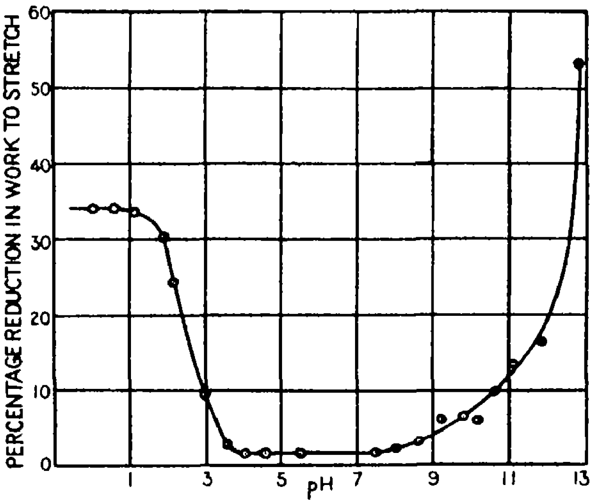

FIG 1

rule The method, which we believe to have a general application, took its origin in the observation that the resistance of wool fibres to extension is far less in acid solution than in distilled water This, and the well known ease of extension of fibres in alkaline solution, give a method for studying the stability of the keratin in various media

Briefly the experimental procedure was as follows the work required to stretch fibres 30 per cent of their length was determined at 22 2° C, first in water at a standard *p*H of about 5 5 and then in the medium under examination, twenty four hours being allowed in each case for the fibres to attain equilibrium Extension was limited to 30 per cent because it has been shown that wool fibres can be extended this amount in distilled water without undergoing significant damage Thus, any difference between the two values for the work required to perform this extension is directly attributable to the different actions of the two media, and it is convenient to express this difference as a percentage of the work required to stretch a fibre 30 per cent of its length in water at the standard *p*H

The results shown in Fig 1 were obtained with sulphuric acid solutions on the acid side of the isoelectric point, and with borax, sodium carbonate, and caustic soda solutions on the alkaline side It is clear that wool keratin is completely stable over a range of *p*H from 4 to at least 7 The isoelectric point of wool, as determined by one of us[2] in 1925, is at *p*H 4 8, and it is interesting to recall that Svedberg[3] states that, for the proteins he examined the isoelectric point "is never situated in the middle of the stability region but is always more or less shifted in the direction of low *p*H values"

The similarity between wool keratin and the proteins studied by Svedberg is not confined to the existence of a stability region and the location of the isoelectric point, but is much more fundamental in character For example, he states that the decomposition of a protein in solutions at a *p*H outside the stability region is in many cases reversible that is, if the mixture is restored to a *p*H situated within the stability region, molecules of the original weight are built out of the fragments Similarly, it has long been known[4] in the case of the wool fibre that the action of $N/100$ sodium carbonate is reversed by the mere removal of the reagent by washing in water More recently the action of acids on wool has also been found to be reversible For example, wool fibres in 4 8 N hydrochloric acid required 39 per cent less work to perform a given extension than in water, but, on washing the fibres free from acid, the resistance to extension reverted almost completely to its original value in water

The complete parallel which thus exists between wool keratin and the proteins studied by Svedberg is important because of certain peculiarities in the action of acids on wool, which have a bearing on his conclusion that the proteins forming one of the two groups defined by him have molecular weights 1, 2, 3, and 6 times 34 500 The action of 98 100 per cent formic acid on wool is instructive In this medium, dry fibres give a load extension curve which is exponential in its initial stages in contradistinction to the normal curve for wool fibres in water, which shows a well defined Hooke's law region up to a stress of 4×10^5 gm/cm^2 Silk filaments in formic acid fail to give an X ray fibre diagram,[5] and a similar observation may be presumed true for wool, suggesting that the long chain protein molecules are freed from their mutual attractions to a very great extent in this reagent Thus the exponential type of load extension curve given by fibres in formic acid would be attributed to the free uncoiling of the molecules in the manner suggested by Astbury,[6] and calculation from the curve shows that the limiting extension to be expected by this process is 28 4 per cent, in close agreement with the value previously deduced[4] from the load extension curve for wool fibres in water and that found by Astbury[6] from X ray studies of stretched wool (about 30 per cent)

Such close agreement can leave little doubt that in formic acid the individual long chain protein molecules of the micelles are greatly freed from their mutual attractions Since the action of both organic and inorganic acids is to reduce the resistance of fibres to extension, it may be presumed that in all cases their essential function is to free the molecules in this way On this view, however, all acids would be expected to show precisely the same behaviour at comparable concentrations and it is here that difficulty is encountered As shown in Fig 1, the resistance of wool fibres to extension in $N/10$ sulphuric acid solution is 33 per cent less than in water, and since the

corresponding value for 11 N sulphuric acid solution is only 39 per cent (including true chemical damage), it is clear that the truly reversible action of sulphuric acid on wool is complete at about $N/10$ concentration The behaviour of hydrochloric acid is strictly comparable with that of sulphuric acid, but formic acid, on the other hand, gives a reduction in the resistance to extension of about 60 per cent, its action being still almost completely reversible Similarly, the swelling of wool fibres in formic acid is of a different order of magnitude from that in sulphuric acid solutions Thus, although the action of these and other acids is of the same general type, gross differences in the extent of reaction exist

It is here that support is given to, and an explanation of the phenomenon derived from, the theory developed by Astbury in the preceding letter If the wool molecule should exist in the condition of a self contained threefold screw of pairs of chains, it is clear that the simplification of this condition can occur in several ways either by the formation of the crystallographic sub groups— three pairs of chains or two triads of simple chains—or by the formation of individual molecular chains On this view, the different reactivities of formic and sulphuric acids with wool would be attributed to the ability of formic acid to carry the simplification of the structure to the stage of individual chain formation, while with other acids simplification must cease at one or other of the intermediate stages If this hypothesis is true, it is clear that the adsorption of acid by wool will be accompanied by the creation of new surfaces available for adsorption, the nature and extent of these surfaces being determined by the nature of the acid adsorbed On this basis, a convincing explanation of the many anomalies in the adsorption of various acids by wool can be given Indeed, most of the phenomena observed in connexion with the action of acids on wool are difficult of explanation except on some such basis as that given above

Relation between Charge and Stability of Colloidal Gold

IT is believed by most colloid chemists that the stability of a colloid depends on the charge on its particles, and that the greater the charge the greater the stability The results of coagulation of colloids by electrolytes, as well as the effect of dialysis on the stability of the colloid, have been explained on the basis of the above idea Mukherjee and collaborators,[1] however, working on arsenious sulphide sol, found that the stability of this sol is not so directly related to the charge as it is generally believed to be

It is well known that the charge on colloidal gold and its stability towards electrolytes increase with the progress of dialysis up to a certain stage, after which both charge and stability begin to decrease [2] Simultaneous measurements of charge and stability towards electrolytes with the progress of dialysis have been carried out by us to see if there is any definite relationship between charge and stability of colloidal gold

The gold sol was prepared by Zsigmondy's nucleus method, with slight modifications in details The charge measurements were carried out by Mukherjee's method (loc cit), and the stability towards electrolytes was determined by finding the amount of potassium chloride which would be required to produce a definite blue colour The results are shown graphically in the accompanying graph (Fig 1)

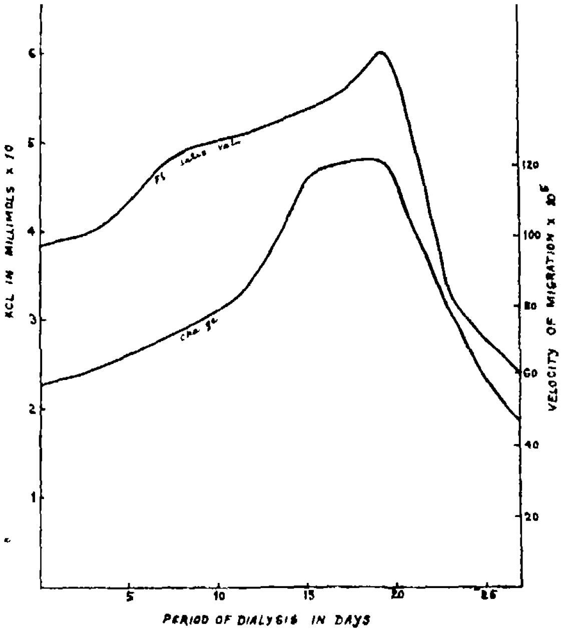

FIG 1

It will be seen from the figure that, with the progress of dialysis, the charge as well as stability increase up to a particular stage (19 days' dialysis), after which both begin to decrease simultaneously We thus find that the stability of the colloid, as determined by its flocculation value, goes hand in hand with the charge on its particles in the case of colloidal gold

The results will be discussed elsewhere in detail A study of other colloids from the same point of view is in progress

Prof A V Saposhnikoff

THE numerous friends of Prof A V Saposhnikoff will learn with much regret of his arrest and exile (NATURE, April 25) I first came into touch with him during the International Congress of Applied Chemistry in London in 1909, and afterwards had the pleasure of working with him during the War and taking him over several of the explosives factories The last time I saw him was in 1923, when he was in England on business for the Soviet Government He is a charming man, and, under the new régime, was trying to serve his country to the best of his ability and to keep out of politics It is now known that he was arrested on Oct 1, but no charge against him has been made public Knowing him as I do, I can only think that his arrest is the result of some dreadful mistake

Prof A V Saposhnikoff was born on Mar 15, 1868

n Siberia, and received his earlier education with he Corps of Cadets in Omsk and afterwards at he Michael Artillery School and Michael Ordnance Academy in Petrograd He was appointed professor of chemistry at the Michael Ordnance Academy in 1899 and held that post up to his arrest He also held other important posts and was widely consulted and received many honours and decorations, including hat of Knight Commander of the Order of St Michael and St George from Great Britain

Saposhnikoff's work has been varied and is well known to scientific workers in Europe Under the Soviet régime he has carried out much work in con nexion with the use of petroleum on Russian railways, the danger of fire therefrom and means of fighting t, the impregnation of railway sleepers, etc His outstanding researches, however, are on the chemistry of explosives and date from the beginning of the present century up to the War He was not satisfied with the empirical knowledge of the nitration of cellulose and thought that a study of the physico chemical con ditions in the mixed acids used for nitration would hrow some light on the question He therefore measured the vapour tensions of mixtures of sulphuric acid, nitric acid, and water and showed the conditions under which all the water is attached to the sulphuric acid and the nitric acid left free, and also when urther addition of sulphuric acid removed the water from the nitric acid, with formation of nitrogen pentoxide These researches were published in the *Zeitschrift für physikalische Chemie* From this work, he naturally went on to study the relation between the nitrating capacity of mixed acids on cellulose and their vapour tensions The chief results were em bodied in a paper which he read at the International Congress in London in 1909, entitled "La théorie de a nitration de la cellulose" Much fuller details are given in his paper in the *Journal* of the Russian Physical and Chemical Society It also appeared in *Zeit Ang Schiess Spreng* This work has justly been regarded as a most important contribution to the understanding of the nitration of cellulose

Saposhnikoff employed triangular diagrams very effectively to illustrate his results, and examined, in the light of his theory, the data of Vieille, Bruley, and Lunge as well as his own, giving an illuminating explanation of the results obtained Indeed, many of his friends look on him as the 'father' of the theory of nitration of cellulose

It is impossible to refer to all Saposhnikoff's work in this note, although one would like to have dealt with his researches in metallurgy I can, however, emphatically endorse the statement made in NATURE that the loss which the world suffers through the banishment of such a brilliant scientific worker is disastrous

Phenomena in a Sounding Tube

IN view of Prof Andrade's recent communication on Kundt's tube effects,[1] the following observations may be of interest The experiments were carried out in 1927 but have not yet been published In our case supersonic sound waves were used, and the effects did not differ greatly, contrary to Prof Andrade's suggestion, from those he obtains with waves of audio frequency

A piezoelectric system was used as a source of the supersonic waves, and powerful oscillations of the order of 1 cm wave-length were radiated along the tube The effects of these waves on magnesium oxide smoke were investigated It may be noted at this point that the size of the average smoke particle in the first few seconds of an experiment was of the order of 5×10^{-5} cm radius or less Hence the individual particles would presumably take up the motion of the sound waves rather than act as obstacles like the dust particles in Prof Andrade's experiments

The first observation of interest was that if one end of the tube were open the smoke was pushed out rapidly When, however, the ends were closed, the smoke was observed to circulate in a somewhat irregular manner After a few seconds, large flocculent particles appeared and perfect rings formed on the sides of the glass tube, similar to those obtained with lycopodium in a Kundt's tube, except that they extended right round the tube, becoming a little thinner at the top

The circulation of the smoke was examined more carefully by means of a parallel beam of light from an arc down the centre of the tube At times a more or less turbulent motion occurred throughout the length of the tube, at others there appeared to be formed vortices at distances apart corresponding to the nodes, and at these points large flocculent particles were gradually built up owing to the rapid coagulation of the smoke Some of these large flocks were in rapid rotation about an axis roughly corresponding with that of the tube They remained suspended in the middle of the tube at the nodes so long as the waves continued If the waves were stopped, the flocks rapidly settled after a minute or so, and the tube was found to be practically clear of smoke, nothing but well marked rings remaining

The Nature of Time

IN NATURE of Jan 31, p 163, F O Wollaston and K W Miller suggest that time consists of discrete sections that is, time has an interrupted structure The element of time is assumed to be equal to h/mc^2, where m is the mass of the electron In connexion with this subject, it should be noted that a similar idea was put forward by Robert Lévy,[1] and was afterwards worked out more closely by myself,[2] Gottfried Beck,[3] Wilhelm Anderson,[4] and Seitarô Suzuki [5] In this way it was possible to establish a range of regularities bearing upon astrophysics and the nature of cosmic rays [6] These regularities also correspond well with Dirac's [7] theory of protons and electrons In all these cases, however, it is necessary to take a smaller element of time than that shown above This elementary interval is equal to h/Mc^2, where M is the mass of the proton

Ozone in the Upper Atmosphere and its Relation to Meteorology *

By Dr G M B DOBSON, F R S

UNTIL nearly the close of the nineteenth century, meteorologists — with but a few exceptions—had been content to confine their attention to studying the atmosphere near the ground When Teisserenc de Bort and W H Dines began to study the conditions up to a height of 20 km or more by means of small balloons carrying light self recording instruments, it immediately became clear that a knowledge of the free atmosphere is essential to an understanding of the physical processes which we include in the term meteorology Since, however, observations have shown that while pressure gradients associated with cyclones or anticyclones, after continuing without great change throughout the troposphere in most cases, fall off rapidly within the stratosphere, and become very small at about 20 km , we have come to regard the domain of physical meteorology as being roughly confined to that part of the atmosphere below about 20 km I wish now to describe some observations that seem to show that there are effects of cyclones and anticyclones which extend up to something like three times that height

About ten years ago, MM Fabry and Buisson first showed that there is a very small amount of ozone situated at a great height in the atmosphere, and they also developed methods by which the amount could be measured with considerable accuracy The actual amount is very small, but, as will be shown, it has very important effects If the various gases of the atmosphere were all separated from each other and brought to a layer uniform in density at normal temperature and pressure, the thicknesses of the layers of different gases would be as given below

Gas	Nitrogen	Oxygen	Argon	Carbon dioxide	Neon	Helium	Ozone
Thickness	6 2 km	1 7 km	76 m	2 4 m	10 cm	9 2 cm	3 mm

This shows how very little ozone there is compared with the other gases, but the effect of even this small amount is by no means unimportant , thus, it prevents excessively strong ultra violet radiation from the sun, which would cause intense sunburn and other effects, from reaching the earth, and it is further responsible for raising the temperature of the atmosphere at great heights to values far above those of the stratosphere and probably nearly up to the normal boiling point of water

Turning now to the methods used for measuring the amount of ozone in the atmosphere, this is always done by spectroscopic means Ozone has an exceedingly strong absorption band in the ultraviolet region between about 3200 A and 2200 A , so that if we measure the absorption of light of a suitable wave length while passing through the atmosphere, we can deduce the amount of ozone through which the light has passed In practice it is not convenient to measure the absolute intensity of one wave-length, but we measure the ratio of the intensities of two adjacent wave lengths, chosen so that one is strongly absorbed by ozone while the other is but little absorbed By this means we largely eliminate changes due to haziness in the lower atmosphere and also changes in the energy emitted by the sun

For most of the work so far accomplished, photographic instruments have been used, and spectrograms of sunlight are taken under carefully controlled conditions so that the energies in the different wave lengths can be accurately determined With these instruments there is naturally a most inconvenient delay due to developing and measuring the plates before the ozone content can be deduced , further, the labour is very great Photoelectric methods are now available which allow exceedingly small amounts of light to be measured, and these when used in conjunction with a suitable double spectroscope, allow the ozone to be easily measured within a total time of about five minutes at all times when the sun is more than about 10° above the horizon, whether the sky be cloudy or not If the sky be clear, measurements can be made even when the sun is much nearer the horizon Indeed we may say that, provided the sun is sufficiently above the horizon, we can measure the amount of ozone in the upper atmosphere nearly as easily as we can measure the barometric pressure and with an accuracy approaching that of barometric readings, when we take into account the 'correction to sea level' to be applied when comparing barometer readings at different places, which is often rather uncertain for stations at some little height above sea level

The height of the ozone in the atmosphere can be deduced by taking measurements when the sun is rising or setting, since in these conditions the calculation of the amount of ozone involves both the height of the ozone and the curvature of the earth The method is not very accurate but a large number of measurements show that the average height of the ozone layer is about 50 km above sea-level We do not yet know how far above or below this height the ozone layer extends

When measurements of the quantity of ozone are made in temperate latitudes, it is found that there are large variations in the amount present from day to day, amounting to nearly 50 per cent of the mean value There is also found to be a well marked annual variation, having a maximum in spring and minimum in autumn The day to day variations show a close connexion with the meteorological conditions in the upper troposphere and lower stratosphere, the amount of ozone being high when the temperature of the troposphere is low, when the pressure near the base of the stratosphere is low, and when the height of the base of the stratosphere is low, and vice versa The number of meteorological observations reaching a height of more than 15 km is not very large, but such observations as there are indicate that the amount of ozone is closely related to the pressure up to the

* Friday evening discourse delivered at the Royal Institution on Mar 6

greatest height where observations are available It has also been shown by Dr Duckert that the amount of ozone is closely related to the density of the air about 15 km and above but not with that at a lower level Considering that the comparison has necessarily to be made between ozone measurements made at one place and meteorological observations made 90 km or more away and often some hours different in time, it is remarkable that correlation coefficients so high as 0 80 have been found

When the distribution of ozone is compared with the distribution of barometric pressure, a close relationship is again found Unfortunately, the meteorological observations are not available from which maps showing the distribution of pressure and temperature at various heights in the atmosphere can be drawn, but even the surface distribution shows that the two are closely associated Observations were made at seven places in north-west Europe in order to study this relationship during 1926 and 1927, and the distribution of ozone in the different regions of a typical cyclone or anticyclone are shown in Figs 1 and 2* At the time when these measurements were made, only the older photographic spectrographs were available, and these could not be used when the sun was low or when the sky was cloudy, so that measurements had to be stopped during the winter, and even in the summer a large number of days were missed owing to cloudy skies Thus the information at present available is very meagre, but there is no doubt whatever that in practically all cyclones the distribution of ozone is roughly as indicated in the accompanying figures, and there are indications that cyclones only form when there are large differences of ozone in adjacent regions It was seen that the relation between the amount of ozone and the meteorological conditions at any one given place is very much closer if the conditions in the upper air are taken than if surface conditions are considered, and there is reason to think that if we were able to draw pressure and temperature maps for a height of, say, 10 km., we should find that the distribution of ozone

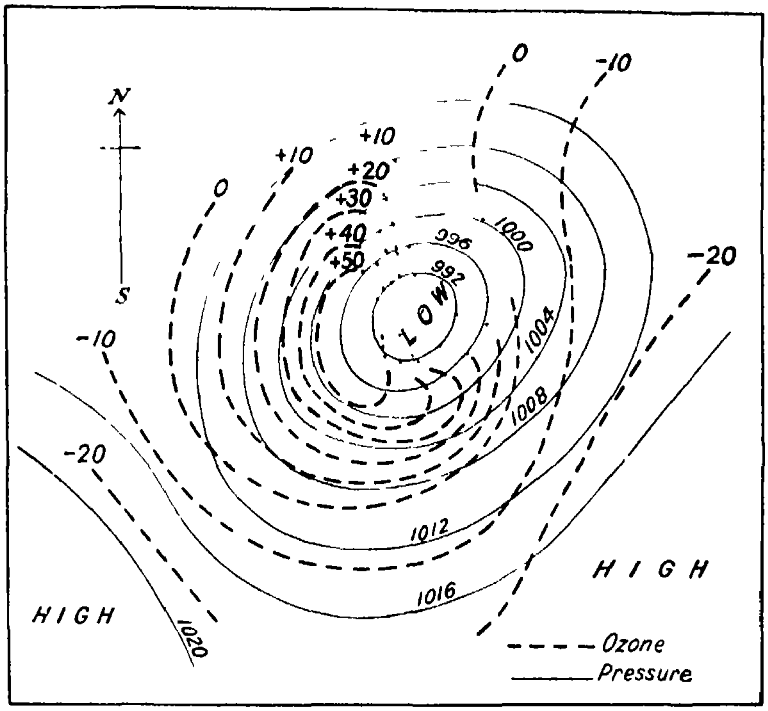

FIG 1

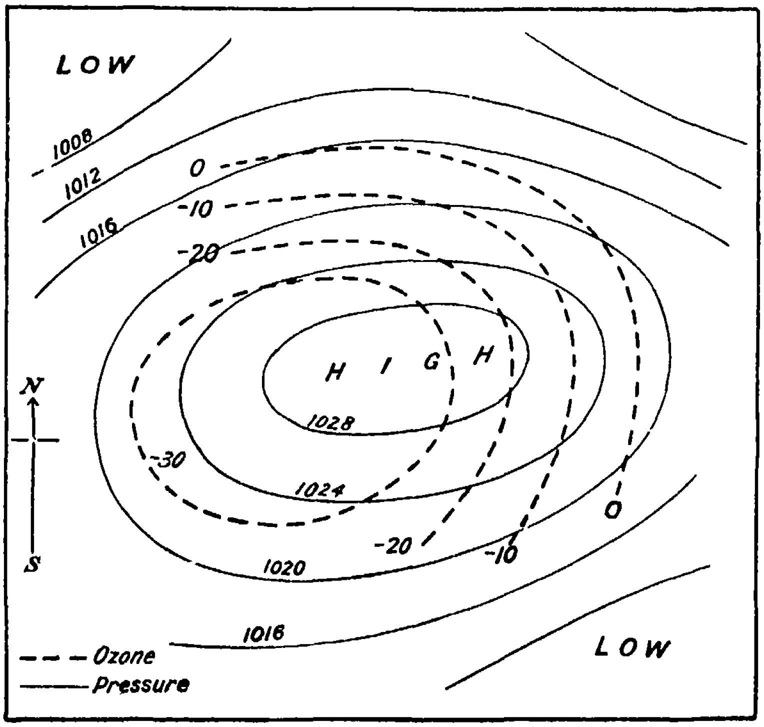

FIG 2

* The illustrations in this article are reproduced, by kind permission, from the *Proceedings of the Royal Society*

showed an even closer connexion than that found using maps for the surface

When we turn to the distribution of ozone over the whole world, we find that the relatively few measurements so far made give a fairly definite picture of the main outlines These are best seen from Figs 3 and 4, which both show the same results but presented in a different manner It will be seen that at all latitudes outside the tropics there is a definite annual variation, with maximum in spring and minimum in autumn both in the north and south hemisphere Within the tropics the amount of ozone is small at all seasons, and it is noteworthy that even such big changes as the Asiatic monsoon appear to have no effect on it, presumably because the ozone is at a much greater height than is reached by the monsoon In the spring there is a very rapid rise in the amount of ozone from the equator to the pole, the amount at the pole being more than double, and possibly treble, that at the equator On the other hand, in autumn there is but little change in the amount of ozone over the whole hemisphere These results seem to be true for both north and south hemispheres, and though there have been only about one year's observations at most of the stations, it is thought that while another year may give slightly different values, the general conclusions are not likely to be changed

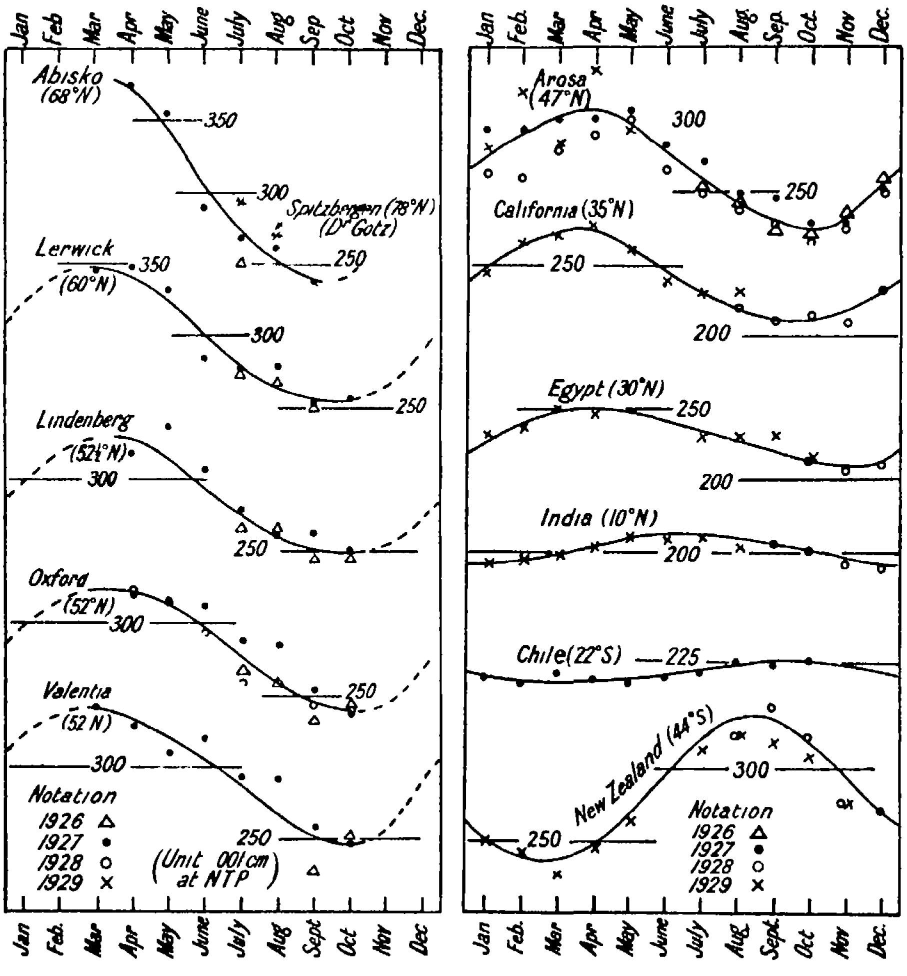

FIG 3

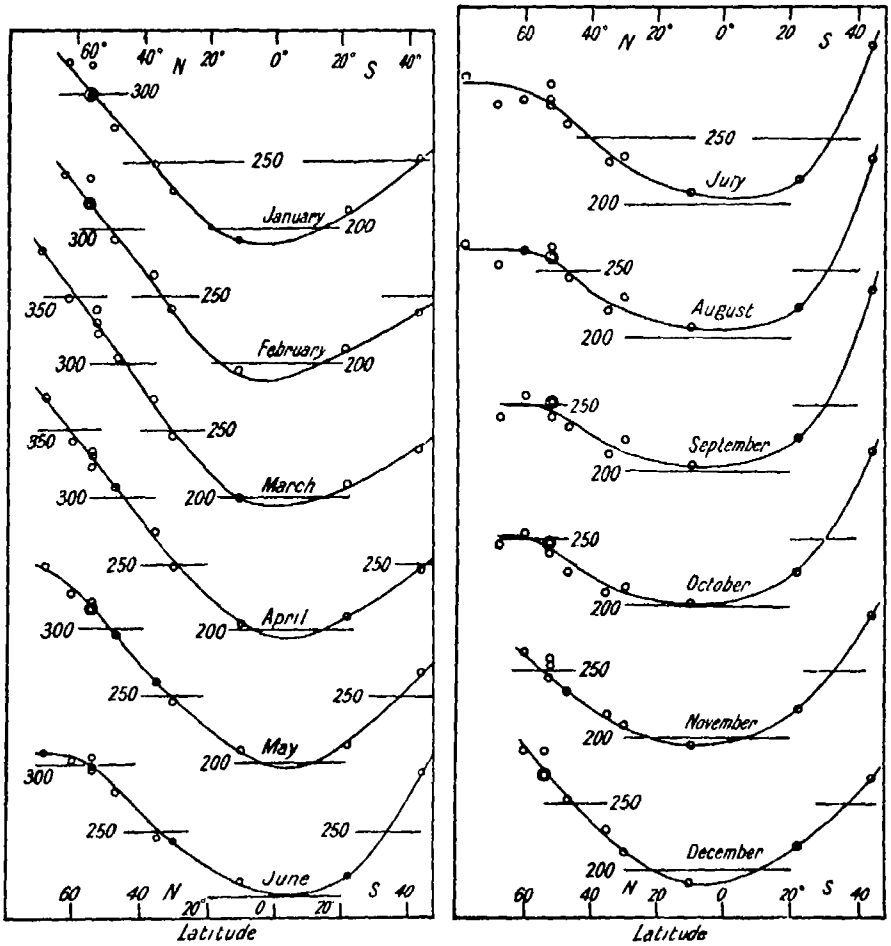
We come now to the obvious questions What forms the ozone in the upper atmosphere, and why is the amount so closely associated with the other meteorological conditions if the ozone is really at a height of some 50 km ? It was at first supposed that the shorter wave-lengths of the sun's radiation, by breaking up oxygen molecules into atoms which combined to form ozone, was the chief cause This view is difficult to reconcile with the high value found in polar regions in the spring and the steady low value within the tropics It has been thought that this difficulty can be overcome, but we believe that it is fatal to the view that solar ultra violet radiation is the chief cause Since there have never yet been more than seven stations measuring the amount of ozone in Europe at one time, it is not possible to say for certain whether the amount of ozone is ever increased locally by formation over a limited area, but it is probable that this may happen If so, it would be quite fatal to the hypothesis of ultra-violet light, since it would seem that this must affect a large area of the earth's surface alike The only other suggestion is that it is formed by some action connected with the aurora This would account for the high values at the poles, and in this case there is no reason why ozone should not be formed in small local areas The annual variation is also easily accounted for on this view, since Dr Gowan has shown that owing to the absorption of about six per cent of the sun's radiation by the ozone, its temperature will be relatively high and the higher its temperature the faster will it decompose Hence we should expect the amount of ozone to be small after the sun has been strongest and large when the sun has been cut off, as at the poles at the end of the winter There is, however, at present, no certainty in this matter

The relation between the amount of ozone and

the meteorological conditions presents even greater difficulties There are good reasons for thinking that the average height of the ozone layer is appreciably the same at all times of the year and whether the amount of ozone present be large or small This seems to rule out any suggestion that in polar regions there is ozone in the lower stratosphere and that this is carried to lower latitudes by the polar currents which are well known to be associated with cyclones Even if we suppose that the great polar and equatorial currents extend up to 50 km and so transport ozone at this height, there are difficulties, for, as shown above, while there is a great difference between the amount of ozone at the pole and the equator in spring, there is but little difference in autumn, so that on this hypothesis the rear of cyclones should have much ozone in spring but there should be a nearly uniform distribution in autumn This is far from being the case

Again, so far as we can tell at present, the amount of ozone in the rear of a cyclone in Europe during the autumn seems to be greater than the normal amount anywhere within that hemisphere at that season Thus, there is nowhere from which the ozone might have been transported, and we are almost driven to supposing that it is formed in the area where it is found If this is so, there are three possibilities either the presence of a cyclone causes ozone to be formed in the atmosphere above it, or a local increase in the amount of ozone leads to the formation of a cyclone in the atmosphere below it, or thirdly, both cyclones and ozone are formed by some common agency At present it does not seem possible to settle this question without further and fuller observational material, and for this reason it is hoped to organise ozone observations at at least a dozen stations in Europe with the new photoelectric instruments, which have none of the disadvantages of the older photographic ones, and one may hope that results of great meteorological interest will be obtained

In addition to the connexion between the amount of ozone and the meteorological conditions in the lower atmosphere, there are also other notable effects produced by it Although the amount of ozone is so small, its absorption band in the ultra-violet region is so strong that it absorbs practically all the solar radiation of wave-length shorter than about 3000 A reaching the outer atmosphere Altogether, it absorbs about six per cent of the incoming solar energy Thus, one effect of the ozone is to reduce enormously the power of the sun to produce sunburn, and it would be impossible to stay long in the sun without serious effects if it were not for the atmospheric ozone



c d

FIG 4

Another effect of the absorption of so much solar energy in the high atmosphere is that the temperature at these heights is raised much above that lower down Since the ozone has only a weak emission band in the infra-red, it cannot easily lose energy by radiation, and most of the heat absorbed in the high layers is probably radiated by the small amount of water vapour there Estimates made by Dr Gowan of the temperature show that at a height of 50 km a value of 400° A is not unlikely Dr Whipple has shown that the high temperature at heights of about 50 km is responsible for the abnormal audibility of sound from great explosions at distances of 200 km or more from the source Measurements made by

Dr Whipple on the sound waves from artillery fire in Great Britain indicate temperatures up to nearly 400° A at a height of some 45 km, agreeing well with Dr Gowan's estimates

If the ozone is formed by some action connected with the aurora, we should expect that the amount of ozone would show a connexion with the intensity of the visible aurora Unfortunately, with the instruments which were used until recently, it was not possible to make measurements of the amount of ozone in the higher latitudes in winter, and as the aurora cannot be seen in summer, there are too few suitable observations to determine with certainty whether the effect is shown or not There is, however, a small but definite connexion between the amount of ozone and terrestrial magnetic conditions, days of high magnetic character tending to have much ozone, and vice versa This is what we should expect if the ozone were associated with the aurora It is also significant that a large amount of ozone seems to be associated with magnetic disturbance but not with a large amplitude of the normal diurnal variation on magnetically quiet days, which we may suppose to be due to increased ionisation caused by ultra violet radiation

This is, briefly, the state of our knowledge of atmospheric ozone at the present time, which is due to researches by several workers during the past five or six years When the whole story of the part played by ozone in the extreme upper atmosphere has been unravelled, it seems likely to afford material of great interest

The Centenary of the British Association

IN 1831, when the British Association was founded, the opinion was freely expressed that there was no useful work for it to do At the very successful jubilee meeting at York in 1881, fears were felt for the future the view was held in some quarters that the Association's work was done

> "At York they thought she was sure to die,
> For she didn't seem to enjoy age "

So roared the Red Lions of the day, rather mysteriously feminising the 'British Ass' An interesting historical parallel has already been encountered in the present centenary year—an expression of precisely the same opinion by more than one person unconnected with the Association There is therefore every reason to hope that at least another century of useful work lies before it

Certainly the preliminary programme of the meeting shows promise of exceptional interest for scientific workers and laymen alike The programmes of the Association can never be accused of pandering to the public interest It is not necessary that they should If a discussion with an arresting headline happens to appear (such as "The Evolution of the Universe", which is found in the present programme), it may be taken that men of science have something to say on this subject to each other, not that they merely wish to tickle the curiosity of the public Actually they can do both, and in the present year, what with the Faraday centenary immediately preceding, and the Clerk Maxwell celebration, and the jubilee of the Natural History Museum immediately following the Association's week, there ought to be a gathering of the 'cultivators of science' (to revive the phrase of 1831) such as has never been seen before, in Great Britain or elsewhere The Association, at any rate, is doing what it can to give the occasion an imperial and, indeed, a world-wide significance by inviting representatives from all the places where it has met in the past, both at home and in the dominions, and also a notable list of foreign guests Already there is a welcome response to these invitations Fairfield Osborn, Gregory, and Cattell, Adamson, Torry, Kerr Grant, and McLennan, Ehrenfest, Zeeman, Thilenius, Sergi, Hevesy, Debye, Matschoss—these are names taken almost at hazard from the list

The mechanism of the Association is adapted by experience to a meeting in any large town except London Anywhere else than in London the civic and the cultural spirit of the place forms a unit which never fails to co operate in receiving the Association, powerfully aiding its organisation in all that appertains to local arrangements, and providing a quota of local members to take the opportunity of participating in its transactions In London there is no such unit it is too big Not that there can be suggested any lack of co-operation, when the City through its Court of Common Council first expressed the hope that the centenary meeting would be in London, and the Lord Mayor recently presided over a meeting held in Guildhall to hear the Association's aims when H M Government has promised a reception, when the London County Council, the City of Westminster, and the Royal Borough of Kensington through their principal officers have shown active interest in the arrangements, and when all the great institutions in South Kensington have freely lent their splendid accommodation for the meeting and promised other facilities Moreover, members attending the meeting will have a unique opportunity of visiting, again with the generous co-operation of the authorities concerned, a selection of the places of scientific interest in London at large, of which places the number is immense, and members will not fail to realise that this opportunity, so far as concerns the Association, will presumably not recur until 2031 Accepting these good gifts, but knowing that it has not on this occasion a local organising unit with which to deal, the Association has set itself to undertake a good deal of the 'local' side of the arrangements, and has backed its luck in respect of their cost The unknown factor at present is the response of the London public to the stimulus of an Association meeting, the support by way of membership and financial contribution which may be looked for in London

John Perry, the former general treasurer of the

Association, was wont to say that the centenary meeting must be held in London He viewed the occasion with a treasurer's eye, hoping for a great membership and a substantial addition to the funds Without doubt, also, he foresaw the need for a more adequate permanent endowment of the Association The writer was present when Perry was told of Sir James Caird's gift of £10,000 to the Association at the Dundee meeting in 1912 "Very liberal", was his comment, in effect, "it should be an example to others", and thereafter he was concerned to persuade the donor that the whole sum should not be spent at once (as was at first desired), but held as an endowment toward the researches which the Association helps with grants The example was indeed followed in later years, by the late Sir Charles Parsons and Sir Alfred Yarrow, whose benefactions to the Association were made for its 'general purposes', and by Mr Buckston Browne, whose gift and endowment of Darwin's house at Downe have already so far reacted upon the general purposes of the Association that it has materially enhanced its prestige

The Association has undertaken a heavy task in trying to raise the Centenary Fund of £40,000, primarily because, in colloquial phrase, times are bad, and partly, perhaps, because it is not possible to set forth one big immediate object There are, of course, the extraordinary expenses connected with the London meeting will London take note of this? For the rest, the appeal is made rather because those responsible for the administration of the Association, looking to the future as well as viewing the past, know that the Association might better use its high position and influence if it had the means This is not the place to discuss all the objects of the appeal—they can be learned from the official statement, which has been widely distributed and can be obtained from the office on request In brief, however, the Association is, in a financial sense, an exacting guest of those places where it is invited to meet, an exacting taskmaster of those who voluntarily serve it too much so If any centre of human culture conceives that it would be benefited by a visit of the Association, it should in theory be possible for the Association to answer "Yes, we will come", instead of being compelled to ask the question, "Can you raise so much of a fund for our reception, and assure us of a sufficient membership?" This question is becoming the more pressing at the present time, because from more than one quarter of the overseas territories of the British Empire inquiries are reaching the Association whether there could be held in them, not a full annual meeting, but a congress of representative workers in all departments of science from the homeland, to meet the cultivators of science on the spot This would introduce a principle new to the working of the Association, but how desirable! It is to be remembered also that the Association is the only body in the Empire qualified by the breadth of its field to meet such requests, but financially it is not qualified

Consider, again, the grants for research which the Association has honourably if modestly maintained without intermission since its very early years Its administrative expenses, small as they are in comparison with the immense volume of voluntary effort by which its working is really carried on, and much (too much) of them as it delegates to the funds voluntarily contributed to the local organisations in the places where its meetings are held, depend in large measure upon its membership subscriptions But suppose that those expenses were covered by its permanent endowment Then, indeed, the Association would have a rallying call for membership which at present is wanting The invitation to membership would mean not merely an invitation to a week's scientific meeting, as it does now, but also the ability to state that membership of the Association connoted the support of research—and that would give the Association what it now definitely lacks a much wider appeal for permanent, as distinct from temporary and fluctuating, membership "Every membership subscription is a subscription to scientific research" If the Association could start its new century with that slogan, its supporters could feel that they had built truly upon the foundation laid in 1831

Obituary

PROF W C M'INTOSH, F R S

THE death of Prof W C M'Intosh at St Andrews on April 1, at the patriarchal age of ninety two, broke a link with the great naturalists of a long past epoch and closed a career pursued to the very end with single minded devotion and an industry that seemed as if it could never flag Only ten days before, he had come to London to preside at a meeting of the council of the Ray Society, but the long train journey back to St Andrews in a bitter east wind proved too much even for his iron constitution

William Carmichael M'Intosh was born at St Andrews on Oct 10, 1838 He was educated at Madras College and at the Universities of St Andrews and Edinburgh, where he studied medicine He received the degree of M D at Edinburgh in 1860, and was awarded a gold medal for his thesis, "Observations and Experiments on *Carcinus mœnas*" This essay, which he republished a few years ago, dealt mainly with the physiology of the nervous system in the shore-crab and its reactions to various drugs He specialised in the study of mental disease and published several papers on the subject, becoming superintendent of the Perthshire Asylum at Murthly in 1863

At Edinburgh, where he studied anatomy under John Goodsir, M'Intosh had published a paper on the arrangement of the muscular fibres in the heart of the bird, but another of his teachers, G J Allman, seems to have turned his attention more decisively towards marine zoology, a subject

that had attracted him since his boyhood on the shore at St Andrews He began early the long series of faunistic papers which were continued down to the last years of his life, on the marine invertebrates, chiefly of the North Sea, but with occasional excursions so far afield as the Outer Hebrides and the Channel Islands A number of preliminary papers led up to his great monograph of the British marine annelids, published by the Ray Society, of which the first volume, dealing with the nemerteans, appeared in 1873–1874 and was at once recognised as marking a great advance in the knowledge of these animals

The nemerteans are in some ways a peculiarly difficult group for anatomical study Many of them are too large for examination of the whole animals to reveal much of their structure Their pulpy consistency and the fact that the organs are embedded in a continuous parenchyma make dissection all but impossible, and the technique of section cutting was then in its infancy Later investigators, with vastly improved methods, have added much detail but have found surprisingly little to correct in M'Intosh's work Dr Otto Bürger, in his monograph of the Naples nemerteans, refers to "Die glanzende Monographie von M'Intosh" as having reduced to order the chaotic systematics of the group Many years were to elapse before the continuation of the monograph, and the remaining volumes, dealing with the Polychæta, *although of great and permanent value*, had not the novelty and importance of the nemertean work

Meanwhile M'Intosh had dealt with collections of polychætes from many parts of the world, the most important being that of the *Challenger* expedition, on which two stately volumes were published in 1885 In the course of his work on the *Challenger* material he received, for study, the specimens of the problematical organism which he named *Cephalodiscus*, which had been sent to various other specialists and returned by them as not belonging to the groups they were studying M'Intosh gave a detailed description of *Cephalodiscus* and correctly recognised its affinity to *Rhabdopleura*, but it was Harmer who, in a postscript to M'Intosh's report, pointed out its relationship to the Chordata

In 1882, M'Intosh was appointed to the chair of natural history in the University of St Andrews, which he was to hold until 1917, and shortly afterwards he took up another line of work that engrossed his attention for many years While at Murthly, he had published several papers on the life-history of the Tay salmon, and it was no doubt this that led to his selection to conduct investigations for the Royal Commission under Lord Dalhousie, which began in 1883 to inquire into the problems raised by the introduction of beam trawling and its effect upon the sea fisheries Although by no means immune to the discomforts of work at sea, M'Intosh threw himself into the task with his wonted energy and enthusiasm Perceiving the need for laboratory work on shore, he succeeded in establishing at St Andrews the first marine laboratory in Great Britain This was opened in 1884 in a small wooden building which had been hastily erected a few years before for use as a fever hospital It is scarcely too much to say that for the next ten years this mode[st] establishment was the headquarters of Britis[h] marine research The list of zoologists who worked there includes the names of Ray Lankester, Haeckel, Dohrn, Hubrecht, Nansen, Burdon Sanderson, Gotch, and many others of like distinction When, in 1896, the wooden laboratory was replaced by the stone building provided by the generosity of Dr C H Gatty, St Andrews no longer stood alone, and the necessary support became increasingly hard to obtain Since the War the Gatty Laboratory has stood shuttered and deserted

It was in 1865 that the late Prof G O Sars, of Norway, laid the foundation of scientific fishery research in a little paper in which he traced the life-history of the cod and showed that its eggs float on the surface of the sea His work was followed up to some extent in the United States, but it was M'Intosh and his pupils who first showed that practically all our marine food-fishes, with the notable exception of the herring, have pelagic floating eggs, and by their detailed descriptions of the eggs and larval stages made possible the modern developments of fishery research

At the time of his death M'Intosh was the senior fellow of the Linnean and several other scientific societies From the Royal Society, to which he was elected in 1877, he received the Royal Medal in 1899, and the Linnean Society, of which he had been a fellow since 1863, awarded him its Linnean Medal in 1924 He was president of the Ray Society from 1913, and took an active part in its affairs up to a few days before his death

M'Intosh was unmarried Of his three sisters, one, who became the first wife of Dr Albert Günther, was an accomplished artist, and exquisite coloured drawings of marine anim[als] adorn many of her brother's works Her s[on] Dr Robert T Gunther, curator of the Lewis Ev[ans] collection at Oxford, is a well-known zoologist, [and] the family tradition in this respect is maintai[ned] by his son, Mr E R Gunther, one of the natu[ral-] ists of the *Discovery* investigations, now on bo[ard] the R R S *William Scoresby* in the Antarctic

To many generations of the wearers of [the] scarlet gown, the erect and dignified figure [of] Prof M'Intosh must have seemed as muc[h] part of St Andrews as the United College To[wer] or the links or the sea Many who never ente[red] his class-room will have learned of his death w[ith] a sense of personal loss W T C

MR T C CANTRILL

MR THOMAS CROSBEE CANTRILL, who died o[n] April 3 at the age of sixty-three years, was one of t[he] pupils who studied under Prof. Charles Lapwor[th] at Birmingham, where he graduated as B Sc A[t] the age of twenty-eight he joined the Geolog[ical]

Survey of Great Britain, and served continuously on the field staff for thirty-one years, being appointed a district geologist in 1914

Attracted to geology at an early age, Cantrill investigated the structure of the Forest of Wyre, and after joining the Geological Survey his work was for a considerable time centred in the South Wales Coalfield under the superintendence of Sir Aubrey Strahan Thereafter he took charge of the West Midlands district, of which Birmingham may be regarded as the centre, but he also edited and prepared for publication several memoirs on the North Wales Coalfield

The principal contributions made by Cantrill to geological literature will be found in the long series of Geological Survey memoirs to which he was a contributor Thus, for example, he was one of the authors of nine memoirs on the South Wales Coalfield and of more than a dozen other memoirs on the West Midlands and North Wales As a coalfield geologist he had not only vast experience but also sound judgment and great diligence After a breakdown in health in 1921 he resumed his official duties, retiring in 1927, when he took up his residence in his native county of Worcestershire and devoted his leisure to the study of archæology, of which he had always been an enthusiastic student Several contributions from his pen on these subjects have appeared in the publications of local antiquarian societies

Cantrill was a field geologist who showed great devotion to his work and exerted much influence on his colleagues by the strength of his character and the unselfish manner in which he gave assistance to all who made demands on him Though naturally of a somewhat retiring disposition, he made many friends in the districts in which he worked, who were attracted to him by his kindly disposition, his sincerity, and his sympathetic personality

---

WE regret to announce the following deaths

Sir Byrom Bramwell, lately president of the Royal College of Physicians, Edinburgh, and a distinguished neurologist, on April 27, aged eighty three years

Prof Raoul Gautier, honorary professor of astronomy in the University and director of the observatory of Geneva, who was vice president of the International Association of Geodesy, on April 19, aged seventy seven years

Dr Emil Trinkler, known for his explorations in Afghanistan in 1924 and in the Kuen lun Mountains, Afghanistan, and Tibet in 1927-28, on April 19, aged thirty five years

Dr A P Weiss, professor of psychology at the Ohio State University and associate editor of the *Journal of General Psychology*, on April 3, aged fifty one years

News and Views

FOR many years now, a popular belief has existed that seeds which have been removed from ancient tombs retain their ability to germinate Wheat grain, the so called 'mummy wheat', has been a case in point for several decades This question was brought forward again during the discovery and examination of the tomb of Tutankhamen in 1923, by Mr Howard Carter and Lord Carnarvon, and has received attention from various quarters since that date Now another claim has been made by an American farmer, that wheat taken from the tomb of Tutankhamen has been made to grow, and this fact has received much publicity in the press It is all a question of viability The viability of a seed depends on several factors, both internal and external Some seeds will not germinate immediately, and are said to be dormant, such dormancy again being conditioned by after ripening processes, etc The result is that seed viability varies considerably within the plant kingdom For example, the acorn is viable for one season only, whereas charlock will last for twenty or thirty years Hawthorn, even given germinating conditions, remains dormant for the first season, but immature wheat will germinate, given the necessary conditions, as seen in the case of wheat germinating when still in the ear, during a wet season On the other hand, mature wheat is viable for some considerable time Not only that, the grain will withstand extreme conditions to an exceptional degree

OTHER plants show a similar tendency The subject was discussed in an article by the late W Botting Hemsley in NATURE of May 2, 1895, p 7, exactly thirty six years ago He states there that kidney bean seeds, which had remained in the herbarium at Tournefort for a hundred years, germinated, and *Mimosa pudica* will remain viable for sixty years But the viability of wheat thousands of years old is a different matter Sir E A Wallis Budge states in the *Times* of April 23 that grain from a tomb of date 1200 B C was tested for him by the late Sir William Thiselton Dyer at Kew, and gave negative results Many others, too, have tried since, with similar results Yet, such positive results as claimed by some, need explaining The question is Were such claimants sure of their wheat ? For hundreds of years, the halls of tombs have been used as granaries by the natives The grain can conceivably be ascribed to that, and therefore possibly be only a few years old Also, 'mummy wheat' has become so popular that guides have resorted to tricks whereby they dig up 'mummy wheat' (in the presence of the tourist) which the guides themselves had placed there some time before So far, there has not been one authentic case of 'mummy wheat' being viable, and it is extremely unlikely that there ever will be A viable seed is still living and therefore respiring, however slowly Decay is therefore taking place, since there is no anabolism Such decay varies in rate, but it is not likely that it is so slow as to last over thousands of years

ON April 23, an Empire trade gathering which emphasised the enormous wealth in precious metals of the British Empire, and especially of Canada, assembled at the Acton Precious Metals Refinery for the opening of extensions The ceremony was

followed by a luncheon, at which Lord Weir presided, the Government being represented by the Right Hon J H Thomas, and the Dominion of Canada by the Hon G H Ferguson The extensions have been necessitated by the enormous new supplies of platinum metals recently developed in the Sudbury district of Ontario, as by products of nickel and copper These are expected to be produced in the proportions of platinum and palladium, about 40 per cent each, rhodium, ruthenium, osmium, and iridium, 7 per cent, and gold, 13 per cent When the Refinery was first opened in 1924, its capacity was 40 000 ounces a year, whereas its extended capacity will be 300,000 ounces Since the total world consumption is less than 400 000 ounces per annum, the Acton refinery will be able to refine from Empire sources three quarters of the world's demand

THERE already exists a wide variety of uses for platinum metals and these will naturally be developed further as the new supplies become available Platinum itself, found until recently exclusively in sands and gravels and chiefly in the Urals or Colombia, apart from its use in jewellery, is of first importance to the dentist and the surgeon, and is used extensively in laboratories on account of its high melting point and immunity from most chemical reagents It is also used in the making of permanent photographic prints, in the ceramic industry, in the artificial silk industry for spinnerets, and for many electrical purposes Agriculture throughout the world depends on platinum, as fine platinum gauze is used in the oxidation of ammonia during the manufacture of synthetic fertilisers Of the other precious metals, palladium is used for much the same purposes, but it is anticipated that further uses will now be found One in course of development is the plating of white gold and silver to render these metals non tarnishable The palladium plating of microscopic parts, spectacle frames, and automobile and aerodrome reflectors, to render them non tarnishable, is rapidly approaching the commercial stage The other platinum metals are mainly used to alloy with platinum and palladium Platinum was discovered so far back as 1750, and ruthenium, the last of the group, no more recently than 1845

AT a meeting of the Section of the History of Medicine of the Royal Society of Medicine, under the presidency of Sir Humphry Rolleston, on April 15, his brother, Dr J D Rolleston, an ex president of the section, read a paper entitled "Jean Baptiste Bouillaud (1796–1881) a Pioneer in Cardiology and Neurology" Bouillaud's treatise on diseases of the heart, of which the first edition was published in 1835 and the second in 1841, formed an important landmark in the history of cardiology, his two chief French predecessors in this field being Senac, the contemporary of Voltaire, and Corvisart, the medical attendant of Napoleon The contributions of Bouillaud to cardiology were summed up under the following six headings (1) the first description of the endocardium and endocarditis, (2) his 'law of coincidence', in accordance with which affection of the heart is the rule in acute rheumatism, (3) his elaborate studies of the normal heart, whereby he created a new department of topographical anatomy, (4) the importance which he attached to auscultation of the heart in contrast with Laennec, who under estimated its value in cardiac as distinct from pulmonary diseases, (5) his description of new physical signs in cardiac disease, and (6) his detailed account of congenital heart disease

THE pioneer work of Bouillaud in neurology consisted in his identifying the anterior lobes of the brain as the seat of speech thirty six years before Broca, who, though he localised it more precisely in the third left frontal convolution, acknowledged his indebtedness to Bouillaud, and in showing that the cerebellum was concerned with movements of co ordination, in opposition to Gall, who regarded it a the organ of the instinct of propagation In addition to his contributions to cardiology and neurology, he made an important advance in the study of acute rheumatism, which is still known in France as Bouillaud's disease Although a stalwart vitalist, he was one of the first to recognise the importance of chemistry and physics in medicine, in contrast with his contemporary the great clinician Trousseau, who was inclined to depreciate the value of these studies In conclusion, Dr Rolleston showed by quotations from contemporary literature that Bouillaud never received much appreciation during his lifetime in Great Britain, and suggested that the chief cause of the oblivion into which he had fallen was his practice o repeated and free venesections, with which he persisted long after it had been generally abandoned elsewhere

THE April issue of the *Hibbert Journal* contains an interesting article by Sir Oliver Lodge on "The Interaction of Life and Matter" He attempts to interpret the behaviour of animated bodies in terms of a "biological field", just as the behaviour of inanimate particles is interpreted in terms of an electric or magnetic field He admits that the parallel is not complete "In a gravitational or an elastic or any other field, energy is stored and expended those fields belong to the physical universe, and their energy has to be taken into account In life apparently there is no specific energy Life is not energy, it merely directs the energy which it finds available" The element which life adds is not energy but guidance, it directs energy into channels which otherwise might have been unoccupied Yet how life can direct energy without expending energy itself has always been an insoluble problem

SIR OLIVER LODGE here suggests that the possibility of a directive yet non-energetic agency is not excluded by the present state of physical knowledge "Modern physics has shown that every particle has associated with it something periodic The electron does n now appeal to us as a minute spherical charge a nothing else, it has been found to have someth associated with it, a series of waves In fact, i found that many of the properties of a part

matter can be possessed by what is known as a 'group wave', in other words, that the energy of a particle can be expressed as the energy of a set of group waves, and that these, strangely enough, obey the laws of dynamics. Consequently it is realised that the particle and the wave are much more united than ever they have been before. A wave may exist without a particle. A particle can hardly exist without a wave. The waves seem the most fundamental things." Of these waves, Sir Oliver says that they are "mere forms that convey or transmit no energy", they are in fact "not effectively energetic", "their progress is not like that of a material entity, and yet they are supposed to guide the particle to its destination". In other words, they "exercise a controlling and directing influence without imparting any energy". They may be said to act like the rails which guide a train. The hypothesis suggested is that "these form waves constitute the physical mechanism whereby life and mind operate on and direct material particles". The suggestion is an interesting one, and we shall wait to see how far this application of recent physical theory will commend itself to physicists on one hand and to physiologists on the other.

THE Friday evening discourse on April 24 at the Royal Institution was given by Sir Philip Hartog, on Joseph Priestley. Sir Philip pointed out that Priestley was one of the most conspicuous figures in the eighteenth century, and has always seemed puzzling to his scientific biographers. Some of Priestley's best work is contained in his "History of Electricity" and his electrical papers, which have been very largely overlooked. He discovered that charcoal, blacklead, and red hot glass are conductors, suggested that there was a gradation of substances from the most perfect conductors to the most perfect non conductors, and tried to measure conductivity. He anticipated Cavendish and Coulomb, by showing from an experiment of Franklin, elaborated by himself that the attraction between quantities of electricity varies inversely as the square of the distance. Priestley initiated a new era in chemistry by increasing the number of known species of gas from three to twelve, and paved the way for the revolution effected by Lavoisier. His discoveries of the action of living animals on air, of oxygen on blood, and of the green matter of plants on air under the influence of light, have been of the greatest importance in animal and plant physiology. Finally, it appears from notes for a lecture in the Royal Institution in 1810 that it was a theorem of Newton's and certain observations of Priestley on the diffusion of gases that led Dalton to his atomic theory. Priestley's place in the history of science has been under estimated. There have been greater men of science than Priestley, but few whose discoveries have produced so rich a harvest.

DR. J. F. TOCHER, Croll lecturer in statistical methods in the University of Aberdeen, gave an address on April 24, at the Institute of Chemistry, on probable error in scientific investigations, especially as relating to physics and chemistry. In reviewing the methods of testing the accuracy of results, he demonstrated the fact that it is unsafe to rely on an average alone as representing the real value, even if a large number of observations have been carefully conducted to obtain it. It is necessary to make certain that all systematic errors due to the apparatus, the method, and the observer have been avoided. When these have been eliminated, the individual results follow the law of error and contain only the unavoidable experimental errors, similar to those in making an attempt to measure a yard correctly. The measure of these unavoidable errors is known as the probable error, a single figure which gives a shorthand description of the extent of the variation in individual measurements. Dr. Tocher gave examples among others, of determinations of the atomic weight of hydrogen by Rayleigh, Morley, and others, and showed that, despite the extremely sensitive nature of the apparatus and care taken to secure accuracy, the results show a rhythmical variation. They swing from side to side round a specific value. Sometimes, however the individual results rise beyond the limit of unavoidable or random variations and betray an increase or a decrease which is systematic and avoidable. All that those engaged in research can do is to repeat their experiments until they acquire confidence in their accuracy and are able to formulate a reliable result. The calculus of probabilities has an important place in science; Clerk Maxwell described it as the true logic for this world and the only mathematics for practical men.

THE rapidly growing steel constructional work of the great electric power station at Battersea can now be seen from the Embankment. On St. George's Day, April 23, a remembrance stone, built into the station, was unveiled by Mr. W. F. Fladgate in honour of Michael Faraday, and a speech by Lord Bessborough, Governor General of Canada, who is a former director of the London Power Co., was telephoned by radio and broadcast at the ceremony. Lord Bessborough paid a glowing tribute to Faraday, who is recognised as the founder of the electric industry as we know it to-day. A hundred years ago, after much patient research guided by marvellous foresight, he discovered the phenomenon of the induction of electric currents and tabulated the laws governing it. Lord Bessborough said that science has no frontiers; the whole world is its parish. He pointed out that to Canada the 'white coal' of electrical energy means perhaps more than can be measured in the development of the Dominion. In the great metropolis of the Empire, this potent force is working for the betterment of the people in many ways. Faraday's discovery has been a boon to the world, and the Canadians participating on the other side of the Atlantic remember with gratitude the beneficent debt they owe to Faraday. After the remembrance stone was unveiled at the request of Lord Bessborough, Mr. Fladgate used a telephone near the tablet to convey the thanks of the assembled company to the Governor General.

THE Moorside Edge station of the British Broadcasting Corporation has now been completed. It is

the northern counterpart of the Brookman's Park station It is situated 1100 feet above sea level, about five miles from Huddersfield The three 500 feet masts can be seen from the L M S Railway which connects Manchester with Leeds Work has been begun on the third regional transmitter, near Falkirk, in Scotland The fourth is to be located in Somerset, but the site has not yet been chosen As each of the regional stations will radiate on two wave-lengths, transmitting alternative programmes, and as Daventry (5XX) and Belfast each radiate on one wave length, the whole of the ten wave lengths available will therefore be used The general equipment and layout of the Moorside Edge station practically duplicates that of Brookman's Park Great precautions have been taken to avoid interruptions to the programmes In each circuit, spare valves are provided which can be put in circuit at once by merely operating a switch The condensers and inductances are not bolted down, so they can if necessary be disconnected and removed at once The aerial masts, which form a right-angled triangle, are of lattice steel construction and each weighs 40 tons To avoid any unsymmetrical radiation from the aerials by 'mast shadow effect', each mast is insulated from the earth by porcelain insulators The formation of ice on the aerials, which might overload them mechanically is guarded against by passing large currents from the generators through suitable conductors on the masts, the req[illegible]d heat being given in about half an hour For its regional transmission, the Moorside Edge station will use a wave length of 479 metres, and for broadcasting the national programme it will use a wave length of 301 5 metres

Two valuable papers on standardisation have recently been read The first of these was read to the Royal Society of Arts on Feb 4, by Mr C le Maistre, director of the British Engineering Standards Association, and was entitled "The Effect of Standardisation on Engineering Progress" Referring to the present widespread dislocation of industry, which requires to be made the subject of scientific and systematic investigation rather than of party politics, he said the purpose of his paper was to show, in some small measure, the contribution which standardisation can make towards the solution of the problem by the introduction of greater economy in manufacture and distribution No one imagines there is any single remedy for trade depression, but it is an undoubted fact that standardisation, properly organised, is a most important factor in diminishing the excessive ups and downs from which industry suffers The second paper on the subject was read to the Institution of Automobile Engineers on Mar 3, by Mr L A Legros Commencing with a sketch of the history of standardisation, Mr Legros referred to the formation, in January 1901, of the Engineering Standards Committee, from which the British Engineering Standards Association sprang, to the work of standardisation done in connexion with the motor industry, to the progress of provisional standardisation, and to many practical aspects of the subject Quoting from an article by Mr B D Porritt, he said "Standards should result in something more than the stabilisation of quality and testing, it should be a fruitful field for improvement on both sides. If the time had come to visualise a national standardisation authority, such a body should treat standardisation as a means to the enhancement of the reputation of British goods"

The syllabus for the present term of broadcast talks to schools on rural science has recently been published by the Central Council of School Broadcasting There are two series of talks Mr C E Hudson is giving four talks on "The School Garden", on May 1 and 15 and June 5 and 19 Types of useful flowers for the school garden will be considered, and also methods of propagation by seeds and vegetatively and artificially (grafting and budding) The treatment of fruit trees, with special reference to pruning and fruit thinning, and the effect of such treatment will conclude the actu[illegible] scientific considerations This will be followed by the last talk, which is on the vocational possibilities of horticulture This should prove of exceptional interest, especially to children of rural schools in the vicinity of an agricultural or horticultural college "The Plant and the Soil" will form the subject matter of the other series of talks, to be given by Mr Ward Cutler This series will be composed of four talks, on May 8 and 22 and June 12 and 26 The series will begin by considering soil formation, and then various types, especially clay and chalk, with their typical flora, will be described Some very useful experiments are to be described, experiments which may easily be set up without the necessity for any elaborate apparatus The programme contains several good photographs and diagrams Judging from this pamphlet, the rural schools should look forward to two interesting and useful series of talks

The *Bodleian Quarterly Record*, vol 6, No 68, recently issued, contains a reprint of some exchequer accounts of the reign of Henry VI which give a description of a hitherto unrecorded visit of the King to Oxford in February 1439, the object of the visit being to witness a demonstration by a body of German master gunners and their company of their methods of projecting 'wild-fire', an incendiary composition better known as Greek fire In an introductory note to the documents, Mr E W Hulme says that the German artificers were brought to England by John Solers and that they stayed in Oxford nine days The employment of German artillerists in England was customary at this period On Nov 3, from Henry VI is recorded the payment of £40 "To Gokyn Gunner, Walter Lokyer, Walter Hermanson, and Gerard van Ewe, Gunnemeysters" from Germany, who for a long time remained in the King's service The name of John Solers occurs fairly frequently in the national records In 1438 he was appointed sergeant of the King's tents and pavilio[illegible] and in 1439 he obtained a twenty years' lease of [illegible] mines in Devon and Cornwall producing gold or silv[illegible] at a rent of one-fifteenth of the precious metals. [illegible] place of the German experiments in the history of [illegible] use of incendiary compositions in war can be fo[illegible]

by a study of Col Hime's "Origin of Artillery" and von Romocki's "Geschichte der Explosivstoffe"

THE Council of the National Institute of Industrial Psychology has recently issued its tenth annual Report (for the year ending Dec 31, 1930) In spite of the trade depression, the various activities of the Institute have increased in number and scope, and it is noteworthy that the importance of the human factor in industry is becoming recognised more and more Membership of the Institute has increased from 1430 to 1600, more requests are made for vocational guidance, and investigations have taken place in such varied industries as railways, meat paste, stores, and chocolate An important development is that firms are beginning to send their applicants for posts to be advised by the Institute as to the branch of the work for which the candidates are most fitted Apart from investigations, the Institute is doing research work into the nature and measurement of the mental abilities involved in factory assembly, colour discrimination, tests for perseveration, occupational prospects for boys, tests for motor drivers, etc Lectures and demonstrations have been in increasing demand A special appeal is being made for funds to continue the work, as research work cannot in the nature of the case be self supporting, and in memory of the Institute's first president it is proposed to call it the Balfour Memorial Fund

THE first number (vol I, No 1, pp 1–96) of the new publication, the *Veterinary Bulletin*, has recently been published, as announced in NATURE of April 25, it is to take the place of the *Tropical Veterinary Bulletin*, which ceased publication with the December number, with the addition of matter relating to animal diseases of temperate climates The *Veterinary Bulletin* will deal with all aspects of animal health in so far as they relate to original research and administrative control, but it will not deal with clinical material from the point of view of the practitioner, book reviews will be included The *Bulletin* will be of crown quarto size, 9¾ in by 7½ in, and vol 1 of this year will be issued quarterly and will run to about 384 pages From Jan 1, 1932, the journal will be published monthly and the volume will run to about six hundred pages The journal is published by the Imperial Bureau of Animal Health, Veterinary Laboratory, Ministry of Agriculture and Fisheries, Weybridge, Surrey, England, and the subscription price for the volume is £1, post free, payable in advance to that address (single copies will be 7*s* 6*d*) The subjects dealt with are classified under fourteen headings, most of which are represented in the abstracts in this first number Among the contents we notice that several pages are devoted to the *BCG* (Bacillus Calmette-Guerin) vaccine for tuberculosis, a subject which is attracting much attention at the present time, and nearly seven pages to *Bacillus abortus* infections and abortus and undulant fevers in man, another subject of much importance

THE Zoological Department of the British Museum (Natural History) has acquired, by purchase, a mounted specimen of a gerenuk, or Waller's gazelle (*Lithocranius walleri*) The animal has been mounted standing on its hind legs in the browsing attitude adopted by this species Although this antelope has been known to science only during the last fifty three years, excellent figures of it are found in Egyptian rock-carvings believed to date from about 5600 B C Its distributional range includes a very large part of the desert country of East Africa The Museum has also purchased the skin and skull of a pigmy hippopotamus (*Choeropsis liberiensis*) This species is found in Liberia and Sierra Leone The animal is not gregarious, spends most of its time on land, and is strictly nocturnal in its habits The zoological and entomological collections have been enriched by a large amount of material obtained by Capt A K Totton whilst a guest of the Atlantic Fleet during its recent visit to the West Indies The Department of Geology of the Museum has acquired some Jurassic insects from Bavaria, and a unique collection of Australian Triassic fishes The former are preserved in the famed lithographic stone of Solenhofen, and comprise some exquisite dragon flies The latter were gathered from a quarry, now closed, near Sydney This fish fauna is the only one known from the Middle Trias of Australia H M the King has sent 673 specimens of dried plants from Nepal on loan to the Department of Botany The flora of Nepal is very little known, for only a small area has been explored botanically The Friends of the National Libraries, with the co operation of one of their members, Mr Basil H Soulsby, have presented to the Library a copy of Robert John Thornton's rare work "Botanical Extracts, or the Philosophy of Botany", in four volumes (London, 1798–1810) Dr Thornton (1768–1837), a distinguished member of Guy's Hospital, spent many thousand of pounds on producing botanical works, and in 1811 Parliament sanctioned the Royal Botanical Lottery, to which the Prince Regent gave his patronage

THE general subject of the International Industrial Relations Congress to be held at Amsterdam on Aug 23-29, is announced as "Social Economic Planning—The Necessity for a Planned Adjustment of Productive Capacity and Standards of Living" The main object of the conference is the integration of the economic and political factors responsible for the maladjustment which causes so much unemployment in the midst of economic progress Such resolution of the disturbing factors is essential to political and economic co-operation in the planning and adoption of development policies in production and standards of living if policies are to be based on economic facts The programme includes addresses on the "Significance of World-wide Unemployment", by Dr Max Lazard, Paris, "Recent Growth in the World's Productive Capacity", by Dr Otto Newath, Vienna, "The Problem of Planned Economy", by Dr L Lorwin, Washington, "Principles and Practice of Scientific Management", by Dr H S Person, New York, and H von Haan, Geneva, "Experience and Potentialities in International Economic Treaties", by Prof J. P Chamberlain, New York, "International Planning by Industries", by

Prof M J Bonn, Berlin, "Mass Distribution and Standards of Living", by E A Filene, Boston, U S A, and "International Agreement on Labour Standards", by M Albert Thomas These addresses will be followed by discussions, and other discussions are announced on "Potentialities in National Economic Planning", "The Co operative Movement", "The International Bank Its Potential Relation to Planned Production", and "The Economic Basis of Regional Agreements"

The Advisory Committee on the Welfare of the Blind has issued its ninth *Report*, 1930, to the Minister of Health (H M Stationery Office, 1931 6*d* net) It is estimated that the blind population of England and Wales on Mar 31, 1930, numbered 56,853 Attention is directed to an experiment in sub contracting for the manufacture of 'forms' for telephone bell sets by blind persons There were no complaints as to the quality of the work, and the output was satisfactory, averaging two thirds that of sighted workers The experiment confirms conclusions already reached by psychological analysis, namely, that skill in executing a movement depends both upon a muscular control which is independent of vision and a visual control, and totally blind persons must always suffer a handi cap in this respect

At the end of last year, Prof A A Ivanoff retired from the position of Director of the Observatory in Pulkovo and took over the office of the President Adjoint of the Central Chamber of Weights and Measures (Leningrad, Mezhdunarodny Prosp, 19)

The following have been proposed for election as honorary members of the German Chemical Society A Angeli (Florence), E J Cohen (Utrecht), W Ipatiew (Leningrad), I Langmuir (Schenectady), H Le Chatelier (Paris), Sir William Pope (Cambridge), The Svedberg (Upsala), E Warburg (Berlin)

The following have been elected as officers of the Physical Society of London for 1931-32 *President* Sir Arthur Eddington, *Secretaries* Dr Ezer Griffiths and Dr Allan Ferguson, *Foreign Secretary* Prof O W Richardson *Treasurer* Mr R S Whipple, *Librarian* Mr J H Brinkworth, *Assistant Secretary* Dr J J Hedges, *Editor* Capt C W Hume

The council of the Royal Geographical Society has made the following awards for 1931 The Murchison Grant to Mr L M Nesbitt, for his difficult journey through the Danakil country of Abyssinia, The Back Grant to Col R H Rowe, for his surveys in Nigeria and on the Gold Coast, The Cuthbert Peek Grant to Mr H J L Beadnell, for his explorations in the Libyan Desert, The Gill Memorial to Mr Michael Spender, for his studies of the Great Barrier Reef

A series of lectures, the first under the terms of the Heath Clark bequest to the University of London, will be given on May 4, 5, 6, 7, and 8, in the London School of Hygiene and Tropical Medicine, Gower Street, by Sir George Newman, the Chief Medical Officer of the Ministry of Health and the Board of Education, who has taken as his subject "The Rise of Preventive Medicine" All the lectures commence at five o'clock and are open to the public without ticket

A course of advanced lectures in sociology will be given by Prof E Westermarck at the London School of Economics on May 6, 7, and 8, the subject of the lectures being "Pagan Survivals in Mahommedan Civilisation" The first lecture will cover the beliefs in the jinn, the evil eye, and the curse In the second, Prof Westermarck will deal with the conception of holiness and the closely related beliefs connected with saintly persons, places, and objects In the third lecture he will cover Roman and pagan survivals in Mohammedan ritual Prof C G Seligman will take the chair at the first lecture The lectures will begin at 5 P M, and admission will be free to students and others interested

The thirty sixth general meeting of the Deutsche Bunsen Gesellschaft will be held at Vienna on May 25-28 next The programme includes a list of thirty papers on various branches of pure and applied physical chemistry and a number of excursions and visits to places of interest The titles of the separate lectures show that a wide field of interest both in pure and applied science is to be offered at the meeting The subjects to be discussed include metallography, crystal structure, thermodynamics, spectroscopy, adsorption, and free radicals, and many well-known authorities will take part in the programme The arrangements made for the accommodation of visitors from overseas and for excursions are complete, and the meeting promises to be one of great interest

An invitation is again extended to farmers' and farm workers' associations and clubs chambers of agriculture and horticulture, students' societies, and other bodies interested in agriculture or market gardening to inspect the Rothamsted and Woburn Experimental Plots during the coming summer Mr H V Garner and Capt E H Gregory will be available to demonstrate the plots At Rothamsted the soil is heavy and the experiments deal with the manuring of arable crops and rotation experiments At Woburn the soil is light and the experiments are concerned more particularly with the manuring of potatoes, sugar beet malting barley, wheat, and the use of green manures All communications and requests to visit the Stations should be addressed to the Secretary, Rothamsted Experimental Station, Harpenden

Applications are invited for the following appointments, on or before the dates mentioned —A lecturer in mechanical engineering at the Handsworth Technical College—The Principal, Handsworth Technical College, Handsworth, Birmingham (May 11) A half time lecturer in social economics and tutor academic work in the Department of Social Study the University of Birmingham—The Secretary, The University, Birmingham (May 13) A Bayliss Starling scholar at University College, London—The Secretary, University College, Gower Street, W

(May 15) A research student in experimental physics in the Henry Herbert Wills Physics Laboratory of the University of Bristol—Prof A M Tyndall, The University, Bristol (May 18) Lecturers on, respectively, economics and industrial organisation at the School of Economics and Commerce, Dundee—The Principal, School of Economics and Commerce, Dundee (May 23) Two senior and four junior research scholars at the School of Economics and Commerce, Dundee—The Principal, School of Economics and Commerce, Dundee (May 23) An assistant lecturer in mathematics in the University College of Hull—The Registrar, University College, Hull (May 29) Two tutors for extra mural education in rural areas, under the Joint Committee of the University of Birmingham and the Workers' Educational Association—The Director of Extra Mural Studies, The University, Birmingham (May 30) A Sir Clement Royds memorial scholar in chemistry in the University of Manchester—The Registrar, The University, Manchester (June 1) Instructor lieutenants in the Royal Navy, with university training and an honours degree in mathematics, science or engineering—The Adviser on Education, Admiralty, S W 1

Our Astronomical Column

The Expansion of the Universe —Sir Arthur Eddington contributes a letter to the April number of the *Observatory*, in which he answers some questions submitted by Mr B M Peek The expansion is relative to our ordinary standards of length, for example, the wave length of the red cadmium line may be taken as our standard Secondly, the expansion is modified by gravitational action Where there is periodic motion, as in the planetary system the only effect of the expanding tendency is to lengthen the period corresponding to a given distance from the centre This would be the case also in the rotation of the galaxy He differs from Prof de Sitter, who thinks that the expansion would be effective even in these cases It is only when we come to the large scale of intergalactic distances that the expansive tendency prevails over the attractions of the galaxies on each other and periodic motion is no longer possible He says that the problem may also be treated on the basis of taking the radius of space as constant, and our standards of length and time as shrinking This assumption leads to the anomaly that an infinite number of terrestrial years would have a finite sum, and all matter would disappear in a finite time Thus he prefers the "expansion of the universe" to the "contraction of the atom"

Collision Theory of Novæ —The March number of *Scientia* contains an article on novæ by A C Gifford, of the Dominion Observatory, Wellington, New Zealand He examines the various theories current on the subject, such as collision of star with nebula or with a body of planetary size, but expresses his strong preference for the theory of collision of star with star, advocated so persistently by the late Prof Bickerton The main difficulty of this theory is that, on the average, novæ appear more often than once a year (including telescopic ones), and that examination of the density of star distribution indicates that collisions between them would be extremely rare Also, one might expect to see the stars separately, some years after the outburst, but this has not been reported, the appearance in Nova Pictoris after the outburst did not suggest two stars The theory that the outburst may result from some instability in the star's interior is now gaining favour, but is not noticed by Mr Gifford, nor does he notice the modification of the theory of collision with nebulæ, namely, that this might produce a blanketing effect, causing the star's heat to be bottled up, ultimately leading to an explosion

Comets —Publication No 74 of Copenhagen Observatory gives the following definitive orbit of the periodic comet 1927 III = 1926 *f* (Comas Sola) by J M Vinter Hansen 199 observations are used, extending from Nov 4, 1926, to May 31, 1927 Perturbations by Jupiter and Saturn are applied The question of possible identity with Spitaler's comet (1890 VII) is not dealt with, this depends so much on the exact circumstances of the approach to Jupiter in 1912 that it is better to wait until the next return of the comet in 1935, when the period will be known with exactness The date of osculation is 1926 Nov 30 0

The orbit of comet 1930 *d* (Schwassmann Wachmann) is by Jorge Bobone of Cordoba, using observations from May 2 to July 8 (*Astr Jour*) The elements of comet Pons Winnecke for the 1927 apparition (by B Strömgren) are given for comparison It appears likely that the two comets had a common origin

Comet	1927 III	1927 VII (Pons Win)	1930 *d*
T	1927 Mar 22 1029	1927 Jun 21 064	1930 Jun 14 1756
ω	38 27 50 8″	170 22 35″	192° 18 39 0″
Ω	65 35 41 0	98 8 34	76 48 31 9
i	13 45 43 3	18 56 26	17 29 30 0
ϕ	35 6 26 4	43 17 0	42 46 16 5
log q	0 0452093	0 016698	0 004935
Period	8 52004	6 00054	5 5954
Equinox	1925 0	1927 0	1930 0

T is given in U T The period of 1927 III is in Julian years It will be seen that the longitudes of perihelion of the last two comets (that is $\omega+\Omega$) are nearly identical

Ancient Egyptian Astronomy —Mme Flammarion, who has been travelling in Egypt, contributes an illustrated article to the February number of *L'Astronomie* She notes that the crescent is often associated with the goddess Hathor, corresponding to Venus, and conjectures that Venus may have been seen as a crescent in Egypt The same conclusion has been drawn from the name Ashteroth Qarnayim (Astarte of the two horns), which also corresponded to Venus She reproduces a photograph of the well of Eratosthenes at Assuan and describes the determination of the circumference of the earth which he made with its aid It is pointed out that in the time of Eratosthenes the well was 21′ north of the tropic of Cancer, but it may have been made many centuries earlier, when the obliquity of the ecliptic was greater The article states that, according to an ancient tradition, the sun completely lit up the well of Syene at the solstice This would have been the case about 3000 B C, the date usually assigned to the pyramids A picture of the temple of Denderah shows the winged solar disc, which has been plausibly conjectured to have been suggested by the aspect of the corona, especially at sunspot minimum The article combines ancient with modern by giving a picture of Helwan Observatory, and another of a battery of telescopes set up by astronomical tourists on the terrace of the Winter Palace at Luxor

Research Items.

Excavations in British Honduras, 1930.—The season's work of the British Museum Expedition to excavate Maya ruins in British Honduras in 1930 was planned to cover (1) excavation on the masonry and terrace complex at Pusilha; (2) a survey of the new site and the remains of the prehistoric bridge on the other side of the river; and (3) to bring back the two monolithic stelæ which it had been impossible to remove in the previous season. Capt. F. L. Gruning's report on the season's work is published in the *Journal* of the Royal Anthropological Institute, vol. 60, pt. 2. Owing to exceptional rains, the work of excavation and transport was much hindered, and it was possible to bring back to England only one of the stelæ. The terrace site was generally explored. Owing to lack of time, it was not possible to explore an interesting structure resembling two thirds of a pyramid which was discovered, but a substructure on terrace 3 was excavated and produced some remarkable finely flaked flints, some of which are in the form of snakes and scorpions, and a number of jadeite beads. A carved plaque or pendant, of jadeite from an excavation south of the river, was engraved with a design which the author calls the 'begging jaguar with a glyph head.' This, it is believed, is unique. One of the jadeite beads has a 'turk's head' engraving and recessed cavities for inlay. Remarkable also are certain double shells (of the *Spondylus* genus) which had evidently been imported from the coast and had been buried with the owner. They contained small personal ornaments and had evidently been used as jewel boxes. Among the contents of one was a semicircular pendant of jadeite and blister pearls pierced for suspension.

The Mesolithic Human Remains from Mugem.—In *L'Anthropologie*, vol. 40, No. 4, Dr. Henri V. Vallois reports on an examination of the skeletal remains from the kitchen middens at Mugem, Portugal. Previous accounts of this material have been confined to the remains of a few individuals. These have been re-examined, and all other specimens available have also been measured. All the skeletons here considered come from two middens only, those from the third evidently being of more recent date. The conclusions drawn require certain modifications in the views put forward by previous writers. Although female skulls are certainly more numerous, they are not double the number of the males as stated by Paula; nor do they show the number of aged individuals claimed, although a considerable number had attained years of maturity, say from thirty to fifty years of age. It has generally been agreed that the skulls include both dolichocephals and brachycephals, but this also requires qualification. The mean cephalic index of the dolichocephals is 70·9. Though high, the skulls do not show the tendency to hypsistenocephaly claimed by Mendes Correa. The face is mesoprosopic, mesorhine, and mesognathous. Dental caries is present. Of the brachycephals, which are much less numerous than the dolichocephals, it may be said that their condition does not allow any certain conclusion; they are much deformed, and in such a way as to increase the transverse diameter. Of seven skulls, four without question are mesocephalic; and question arises whether the brachycephalic race of Mugem, of which much has been written, is really brachycephalic. The question must be regarded as open, pending further discoveries, and in future we should speak of the mesocephalic rather than the brachycephalic type of Mugem. The various theories put forward as to the affinities of the dolichocephalic type are unsound. It is probably nearest to Cro-Magnon.

Pictures of Some Abyssinian Birds and Mammals.—Artistic pictures of birds at the same time accurate enough to satisfy the ornithologist, are rare; and therefore the album of coloured reproductions of thirty-two paintings, a *Special Publication* of the Field Museum of Natural History, Chicago, is an unusual treat. It contains twenty-eight pictures of Abyssinian birds and four of mammals, from paintings by the late Louis Agassiz Fuertes. The writer watched with interest the rapid progress of Fuertes' work, from his first rather crude pictures of American birds to the fine finish which he attained, and these Abyssinian pictures mark the summit, as they unfortunately mark the close, of his artistic work. No expense has been spared in creating exact reproductions, and eight and sometimes nine colours have been used in the 'offset' lithographic process. The brightness of the colours and the interest of the forms seized upon by the artist give real charm to the collection, which is published through the generosity of Mr. C. Suydam Cutting.

Growth in the Hermit Crab.—The hermit crab provides opportunities for the study of growth potentials associated with asymmetry, here seen in the larger size of the right thoracic limbs, the right-handed twist of the abdomen, and the strong heterogonic growth of the male right chela. The results of measurements on 56 male and 64 female *Eupagurus prideauxi* are given by S. F. Bush (*W. Roux Archiv f. Entwicklungs-mechanik*, 123-1, pp. 39-79). In the absolute size of the limbs, predominance of the right side is greatest in the chela. Posteriorly it grades over into left predominance starting at the fifth pereiopod in the male, and the fourth in the female. The females throughout show less right predominance. The limbs do not all grow at the same rate; there is a definite gradient, which, the right chela ignored, is identical on both sides of head and first seven thoracic segments. There is a maximum at the 3rd pereiopod, from which point, both anteriorly and posteriorly, the growth rate diminishes in a graded series. In the male the gradient is most marked. Here the chela and following two pereiopods are positively heterogonic, the right chela to an exceptional extent. The latter, though breaking the regular gradient on the right side, does not influence the growth rates of the limbs on either side of it. If the chela exerts any influence on neighbouring limbs, it is in the matter of absolute size, and it is noteworthy that right predominance is greater in the limbs immediately posterior to it than in those anterior. Comparison of males and females shows male predominance, which is greater on the right side and increases during growth, from the 1st antenna to the 4th pereiopod, grading into female predominance anteriorly (eye stalks) and posteriorly. This gradient also has its summit at pereiopod 3, and is broken on the right side by the great predominance of the ch[e]... The growth gradient within the chela is the same... that within the other pereiopods at first, but... centre shifts with increased growth.

On Unsegmented Ova of Echidna.—T. Thoms... Flynn (*Quart. Jour. Micr. Sci.*, vol. 74, part ... 1930) describes two unsegmented intra-uterine o... of *Echidna*. The egg is about 4 mm. in diameter a... has a delicate transparent shell, a thin layer o... albumen, and then the white yolk mass (with th... germinal disc on one side) enclosed in the very th... zona. In each egg, the two polar bodies had be... formed. They are smaller than those described ... *Ornithorhynchus*, and the first polar body is mu... larger than the second and, contrary to what has b... reported for *Ornithorhynchus*, remains undivided.

the second egg the two germ nuclei—one slightly larger than the other—were closely apposed preparatory to the formation of the first cleavage spindle

Inheritance of Mutual Aversion in an Ascomycete.—A further study of the mutual aversion which occurs between the mycelia derived from different spores of the Ascomycete *Diaporthe perniciosa* has been made by Miss D. M. Cayley (*Jour. Genet.*, vol. 24, No. 1), who also reviews the occurrence of this phenomenon in other fungi and its relation to the various forms of heterothallism. She adopts the nomenclature of Correns, in which the simple form of heterothallic condition due to + and − strains is called haplo heteroecious, and classifies five different types of heterothallism in the fungi. From extensive single spore cultures of *Diaporthe* and testing the reactions of the resulting mycelia, she finds that this fungus shows in addition to the ordinary sex heterothallism, a physiological heterothallism based on inter-racial and self sterility factors which influence the sexual affinity of the haplonts but segregate in ascospore formation independently of sex. The capacity for mutual aversion is thus inherited and occurs in two forms: (1) inter-racial, (2) intra-perithecial as shown by the haplo heteroecious form only. The former is a kind of sterility between biological races, the latter a form of physiological self sterility independent of sex. Aversion is marked by a line where two mycelia meet and refuse to intermingle, and the two types of aversion are not visibly distinguishable. Four ascospore generations were grown from a particular pycnospore culture, the results being stated in a factorial scheme. It is found that different asci of the same perithecium can give different types of segregation of the self sterility factors, and that the progeny of a single perithecium may or may not show aversion, dependent upon the type of segregation which has occurred in the formation of the ascospores. Mono-ascospore cultures will not form perithecia and some mycelia can throw mycelia of the opposite (aversive) group. Incidentally, the use of the term archegonium for the female sex organ of a thallophyte is to be deprecated.

Nucleoli of Rice Varieties.—A cytological study of five varieties of rice from Japan, India, Java and Egypt has been made by A. G. Selim (*Cytologia*, vol. 2, No. 1), who finds interesting differences in the nucleoli of various forms. All the varieties have the same number of chromosomes ($n = 12$) and the same size of nuclei, but the nucleoli in the resting stage of the pollen mother cells show constant differences in average size. In the variety having the largest nucleolus, it regularly divides before synizesis into two of equal size. In the next variety, a smaller nucleolus is budded off from the primary one; in the third variety division takes place later (after synizesis), while two other varieties having the smallest nucleoli, usually remain undivided. The nucleolus which is budded off from the primary one remains attached ..., but disappears earlier in the prophase than the ...r, and is believed to contain chromatin which ...ntributed to the chromosomes. It is suggested ... this secondary nucleolus corresponds with the ...eolar body found in *Lathyrus* and other forms. ...lar observations are included on meiosis in the ...aspore mother cells. This is the first case in which ...eties having the same chromosome content are ...nd to be differentiated by the character of their ...eoli. These differences are correlated with the ...ve and absolute size of the single nucleolus ...ent before meiosis begins. The work also con... other evidence that the nucleolus of plant cells ...ins two different substances.

Fossil Reptilian Egg from Yorkshire.—The *Annual Report* of the Yorkshire Philosophical Society for 1930, issued Mar. 31, contains a description by Sidney Melmore of an object in the Edward Wood collection, now in the Yorkshire Museum, from the Lias of Whitby. This, from its general shape and mode of preservation, Mr. Melmore regards as probably a reptilian egg, possibly of a crocodilian. He deduces the size as 8.5 cm. by 6.0 cm. The outer layers, unfortunately, are pyritised and show no structure.

An Extinct Tasmanian Marsupial.—Prof. Wood Jones has re-examined the well-known extinct marsupial from Tasmania, *Wynyardia bassiana*. Hitherto this form has been considered as an Eocene form and as differing in many respects from any living marsupial. Wood Jones, in the *Proceedings* of the Royal Society of Tasmania, 1930, after a careful re-investigation of the original specimen, has come to a conclusion which is in direct opposition to that which has hitherto been generally accepted. More recent research has shown that the beds from which the fossil came are much later than the Eocene and are probably late Miocene or even Pliocene. The animal itself has no character that distinguishes it from modern marsupials and many that ally it to the living genus *Trichosurus*.

Comparative Study of Soil-Profiles.—Under this title a note on an important investigation of soil profiles in Holland and Java (*Mitt. Geol. Inst. Landbouwhoogeschool in Wageningen, Holland*, No. 16, 1930) was published in these columns on Feb. 7, p. 214. Unfortunately, it was erroneously stated that the authors were A. te Wechel, L. Moser, and C. van Aggelen, whereas actually the study was made by J. van Baren, with the co-operation of the three collaborators already named. The writer of the note regrets that Dr. van Baren's name was inadvertently omitted and welcomes this opportunity of making amends to the senior author of the paper concerned.

Effect of Soil Temperatures on Subterranean Insect Fauna.—An account of experiments on winter soil temperatures at Minnesota and their relation to subterranean insect survival has been given by G. Allen Mail (*Jour. Agric. Res.*, **41**, p. 571). A thermocouple method was used for recording the temperatures at 2 inch intervals for a depth of 2 feet of soil under varying conditions, and although the insulating effect of a snow layer has long been recognised, the differences found between temperatures of snow-covered and bare ground were extraordinarily large. In the case of cleared areas, the soil temperatures showed sharp fluctuations, closely following those of the air, and a spread of 12.48° C. was found between the upper and lower layers investigated. The temperature of the snow-covered soil, however, remained much more constant and showed only a spread of 3.5° C. over the 2 feet depth. From laboratory investigations the freezing-points of adults and larvæ of *Melanotus communis* (a species of wireworm) were found to be −13° C. and −15° C. respectively. They would thus be able to withstand Minnesota winter conditions if hibernating below 4 in. from the surface, and experiments where two species of wireworm were buried in outdoor cages at depths ranging from 2 in. to 24 in. supported this view, there being practically no mortality, as the temperatures did not fall below this point. White grubs (chafer larvæ), on the other hand, are much less cold resistant than wireworms and would have to hibernate at much greater depth, below 2 ft., to overwinter successfully. Climatic conditions, may, therefore, be of great importance in insect control. Since wireworm

larvæ are active only in summer and become dormant in winter, a sudden prolonged drop in temperature would probably prove fatal, as the larvæ might be caught too near the surface of the soil Further, since rain was found to destroy the temperature gradient between the different layers of soil, a sudden drop in temperature following such conditions might also bring about a high mortality To some extent, therefore, it might be possible to forecast the severity of wireworm attack according to the previous winter conditions

Quantum Theory of Nuclei In an article in the April number of *Science Progress*, on new aspects of radioactivity, Dr C D Ellis has stated very clearly two β ray problems which still remain to be explained on the wave mechanics The first is that of the distribution of energy amongst the β particles which arise from the disintegration of the nucleus itself, these have both a continuous 'velocity spectrum' and an upper limit to the energy which is at best so indefinite that Dr Ellis concludes that this type of disintegration can occur with an emission of a particle of any energy whatever The whole process appears to take place in some way governed by essentially statistical laws, as in Maxwell's gas theory, but fundamental difficulties arise in that the corresponding fluctuations must occur within a single nucleus, that is, within a volume comparable with that of the electron when it is considered as a particle, and that the peculiarities of this space must be conditioned largely by the movement of the electron The second difficulty is that far more energy which could appear in the form of γ radiation is converted into a corpuscular β radiation within the parent atom than would be expected The difficulty persists even when two modes of transfer of energy into the corpuscular type are allowed for, namely, formation of a γ ray which leaves the nucleus and is converted photoelectrically before it can pass out from amongst the orbital electrons of the same atom, and the assumption of the energy of an excited nucleus, before a γ ray has been formed at all, as the result of a collision made by one of the orbital electrons of the atom in passing through the nucleus No satisfactory solution of either of these problems has yet been proposed, and it remains an open question whether or not they are capable of explanation on the present theories

Pine Resins —A valuable paper upon the resins of the jack pine (*Pinus Banksiana*) appears in the *Canadian Journal of Research*, **4**, pp 1 34, 1931, by Harold Hibbert and John Bernard Phillips The authors examine the methods previously used for the separation of the various constituents from the resin and decide upon a modified procedure in which the resin, originally extracted from the wood by an alcohol benzene mixture, is extracted with ether, and the water insoluble substances in the ether extract later extracted with 5 per cent sodium carbonate, the residue being then subjected to steam distillation Resin acids and fatty acids in the alkaline extract are freed by addition of acetic acid, and are then separated by esterification of the fatty acids by ethyl alcohol and sulphuric acid Steam distillation has yielded a volatile essential oil and a non volatile residue which is saponified and thus separated into fatty acids and non-saponifiable matter The resins of fresh and seasoned timber were compared, the changes in the resin during seasoning appear to be due to oxidation and polymerisation of the unsaturated fatty products and to changes in the resin acids The authors also direct attention to the tendency of the easily polymerisable terpenic products present to yield products of a sticky, tacky nature

The Quinhydrone Electrode —The use of the quinhydrone electrode, discovered by Haber and Russ in 1904, has been considerable since its development by Granger and Nelson and by Bilmann, independently in 1921 The conditions for the reproducibility of th electrode and its value compared with the calomel electrode were published by Bilmann and Jensen in 1927, and now two important papers by Morgan, Lammert, and Campbell have been published in the February issue of the *Journal of the American Chemical Society*, which contain numerous practical details on the use of the quinhydrone electrode In the first paper, the method of setting up and of cleaning the metal part of the electrode are discussed, and the influence of the nature of the metal used Platinum and platinum alloys gave better results than gold, the age of the platinum was of little importance if th electrode was large enough Very small short wire gave erratic results, larger short wires gave consistent results but larger deviations than foils longer lengths of wire Two foils with dimensions larger than 1 sq cm gave differences of potential when measured against one another, of less than 0 000010 volt The second paper deals with the effect of excluding oxygen from the solution and the use of nitrogen in the electrode Quinhydrone electrodes prepared with nitrogen were found to be far more reproducible than those used in air, and the quinhydrone electrode prepared with chemically pure platinum dipping into 0 1 *N* HCl saturated with quinhydrone and stirred with nitrogen was found to be more easily reproduced with great precision than any other half-cell used for reference Gold was less satisfactory than platinum Irregularities in unshorted electrodes, which occur in air, disappear in nitrogen Whereas cells composed of air dried electrodes and mechanically stirred solutions may take an hour to reach equilibrium and unstirred solutions longer, cells with nitrogen stirred solutions take up equilibrium values almost immediately The electrodes need not be dried in nitrogen, if this gas is bubbled through the solution

Hardening of Metals by Rotating Magnetic Fields —E G Herbert has already shown that work hardened metals become still harder when they are subjected to the influence of a rotating magnetic field In a recent paper (*Proc Roy Soc*, A 130, 154) the research is extended to include alloys which are susceptible to age hardening, and a similar effect has been observed By the combined use of ageing, magnetic field, and cold work, the hardness of a 0 8 per cent carbon steel has been increased from 715 immediately after hardening to 1080, whilst a high speed steel has been hardened from 700 to 1000 Brinell The effects observed are extremely complex, and at times temporary or permanent softening results The influence of these alternating magnetic fields is confined to magnetic materials Duralumin sh quite analogous effects and the alloy may be ' hardened' by magnetic means to a distinctly hi degree than is normally possible Even brass sh effects of the order of about six per cent Altho high frequency fields and very rapid rotation of specimen have been tried, it is shown that neithe necessary, an equally marked effect being produ by slowly rotating the specimen for a few seco across the poles of a powerful electro magnet temperature at which the treatment is given appe to have considerable influence on the degree hardening, this being greater for a hard steel 100° C than at room temperatures It is pointed that the process could be applied with ease to t such as drills, milling cutters, dies, etc, howe complicated their shape

Cotton-growing in the British Empire *

THE work undertaken during the year 1929–30 by officers of the Empire Cotton Growing Corporation stationed in the various cotton producing countries of the Empire is summarised in the report now before us Following the lines of the similar reports issued in preceding years, with which it requires to be read, the volume is a record of steady progress

The outstanding feature of the year is the continued success of the Barberton selections of Jassid resistant strains of cotton This success is not limited to South Africa, where it has given a new lease of life to an industry threatened with extinction through the depredations of the insect, it extends through a wide tract of country embracing the whole of East Africa as far as Uganda, and even into the Sudan Though in the latter country U4, the main resistant race did not show up well under irrigation, of the cottons grown it proved itself one of the most resistant to leaf curl Being itself a preliminary selection as yet unstabilised in respect of many characters of economic importance it promises to become, by selection or hybridisation, the parent of numerous strains adapted to one or other of the varied conditions which naturally occur through so wide a stretch of country In South Africa itself selections from U4 are being crossed with Cambodia certain selections from which have proved to be even more Jassid resistant than the original U4

Of the impressions which a perusal of the various reports leaves on the mind, perhaps the most lasting is concerned with the manner in which local conditions force into prominence different aspects of the problem which the organisation has set itself to solve In South Africa the primary problem was concerned with Jassid for on that solution the life of the industry depended With the solution of that problem other aspects are assuming prominence Cotton is here one of a series of crops, it occupies no dominant position Its setting in the rotation is receiving growing attention and progress is recorded in the investigation of that interesting problem of the harmful effect of a preceding fallow In the two Rhodesias if the work at Barberton has removed one danger and provided in U4 a basis for remunerative cultivation, other dangers exist and in the cotton stainer and the boll worm the insect world exercises a dominating position In Nyasaland, soil problems are engaging attention especially in relation to root development In Uganda the varietal question predominates

In that complex area the Sudan the question of staple assumes importance in those areas, like the Gezira in which the Egyptian type of cotton is grown, and much attention is devoted to spinning tests The appearance of leaf curl during the last few years has introduced a new threat into these tracts which has to be met within the group of cottons yielding that class of fibre and here resistant strains of Sea Island afford a promising basis for progress It is of interest to note the suggestion that this resistance may be the result of a capacity to form an adequate root system, for there is in this suggestion further evidence of a growing recognition of the need both for a better knowledge of root systems in general and for a deeper search for the basis of resistance either in morphological character or in physiological reaction While there is still much to learn with respect to the transmission of the disease its development appears to depend in large measure on the capacity of the root system to make use of the particular soil in which the plant is growing

The potentialities of the rain area in the Southern Sudan are being explored and the work as is natural in a country lacking an indigenous system is mainly concerned with variety trials and dates of sowing The necessity of early sowing is clearly demonstrated

* Empire Cotton Growing Corporation Reports received from Experiment Stations 1929–30 Pp xi + 342 (London Empire Cotton Growing Corporation 1931) 2s 6d

History of the Fauna and Flora of the British Isles

THE British Isles with their comparatively small area but considerably varied natural conditions present a number of highly interesting biogeographical problems, the solution of which would bear an important relation to the larger problems of the distribution of organisms in Europe and in the northern hemisphere generally It is not surprising therefore, that the French Société de Biogéographie should have selected the history of the fauna and flora of the British Isles as a subject for its new volume * the third of a series devoted each to the treatment of a separate biogeographical problem, the two previous volumes dealt with the biogeography of Corsica and of the high mountains of the world respectively

The volume represents a collection of papers by ten different authors, writing in French or in English, and each dealing with his special group of organisms in his own way An introductory article, by L Joleaud, on the palæogeographical history of the British Isles, is followed by a paper on mammals, by Mr Heim de Balsac, who discusses not only the recent fauna, but also summarises the post glacial palæontological evidence One of his general conclusions is that the history of the British fauna is in many respects different from that of the European fauna, particularly with regard to the effects of the glacial period, which were considerably less serious in the British Isles owing to their milder oceanic climate The next article by the same author deals with British birds and emphasises the high percentage amongst them of endemic races as well as the presence of certain Mediterranean elements

The spider fauna of the British Isles is analysed by W S Bristowe who divides the country into five zones limited mainly by temperature conditions With regard to the history of the spider fauna, Mr Bristowe believes it to be relatively simple and appears to derive it directly from the continent after the original fauna had been exterminated by glaciation A great portion of his article is devoted to the discussion of a general problem of the aerial migration of spiders as a factor in populating island areas

A full list of British Orthoptera includes only 36 species 10 of them being introduced through human agency The affinities distribution beyond the British Isles and the probable history of each of them, is discussed by B P Uvarov Out of this number, nine species are considered to be relics of a very ancient probably Tertiary, fauna connected with humid and warm climate Another definitely preglacial group of five species, distributed mainly in the Mediterranean region is called Atlantic, and they are regarded as relics of the rich fauna of Atlantis, which continent has probably extended as far northwards

* Contribution à l'étude du peuplement des Iles Britanniques — Société de Biogéographie, 3 pp 193 (Paris P Lechevalier 1930)

as the southern coasts of Ireland and England One third of the fauna, twelve species, exhibit affinities with the present day Siberian and eastern European fauna and are considered to represent the result of an invasion of the steppe fauna originating in the Angara continent This invasion may have happened either after the last glaciation or, possibly, immediately before it

M E Mosely presents a survey of British Trichoptera but abstains from zoogeographical deductions, while stressing the importance of the ecological factors in their distribution

The Heteropteran fauna is analysed by W E China, who recognises in it the Lusitanian, or Atlantic, the American, the Arctic, and the Germanic elements, these being the groups distinguished by Scharff in his well known work on European animals Certain members of the Lusitanian group are xerothermic in their ecological requirements, but their present distribution elsewhere makes it highly probable that they have survived through the glacial periods on the spot, in sheltered situations Most of the species of the American group should be properly referred to the Angara fauna, to which the larger portion of the Germanic group also belongs, but there are species occurring only in America and in western Europe, including the British Isles but not in Russia or Siberia Definite relationship to the American fauna is also shown in the Arctic group Insular variations in British Heteroptera are unimportant and few in number Out of six endemic species, three are doubtful, while the remaining three are probably Atlantic relics

A brief review of British Lepidoptera, by L Dupont, stresses the poverty of the British fauna and the presence of a considerable number of local forms, many of them being melanistic No zoogeographical analysis is attempted by this author

A discussion of the beetle fauna, by J Sainte-Claire Deville, one of the best authorities on the zoogeography of European Coleoptera, is highly interesting and instructive, being illustrated by a series of twenty four distributional maps One of the main conclusions of this author is that there are no sufficient reasons to believe that the Quaternary glaciation exterminated the original fauna On the contrary, a number of species of southern origin (Mediterranean) have certainly survived the glaciation

The last two articles of the volume deal with the flora J Cardot discusses the mosses, and reveals the interesting fact that there is a very close relationshi[p] between the bryophyte flora of the British Isles an[d] that of the Atlantic islands (Canaries, Madeira, a[nd] Azores) There are even several species which do n[ot] occur elsewhere, while certain species occur besid[e] in the subtropics only The author, however, attr[i]butes their appearance in the British Isles to th[e] distribution of spores by air, after the Quaterna[ry] glaciation, which in his opinion has wiped out a[ll] mosses except some boreal species

A J Wilmott in his thorough analysis of the Britis[h] phanerogamic flora arrives at the opposite conclusion, which is based on a critical discussion of geological facts and theories, of the evidence derived from the study of the Quaternary fossil plants, and of the present distribution of floristic elements He believes that the climate of the glacial periods could not have been so severe as to exterminate the original flora completely, and there is every reason to think that the relatively mild and humid climate of Atlantic type prevailed at least in some sheltered situations of the south west of Ireland and England, thus permitting the survival of aboriginal plants As we have seen, this conclusion agrees well with the opinions of the majority of the contributors to this interesting volume

The Name of Mount Everest

MOUNT EVEREST was first observed by the Survey of India in 1849, but it was not until three years later that its great height was realised From the plains of India it is only one among many conspicuous peaks, and its distance from the Indian frontier across the whole width of Nepal often prevents its being seen at all In these circumstances, it was not surprising to find that there was no Indian name for the peak The first names proposed were the Nepalese names Devadhunga and Gaurisankar The first, however, was found to be non existent as a peak name in Nepal, and the second belongs to another peak There was no entry of the surveyors into Tibet in those days, and, in the lack of Indian and Nepalese names it was necessary to find a title for the peak This was done in 1865 by naming it after Sir George Everest, of the Trigonometrical Survey of India

The controversy about the name was discussed by Major S G Burrard in NATURE,[1] and is now reopened by Dr Sven Hedin in his recent German book on Mount Everest Sir Sidney Burrard replies to these suggestions in a paper recently issued by the Survey of India[2] Dr Hedin maintains that the mountain was first shown on D'Anville's map of Tibet published in Paris in 1733 This was based on a survey made between 1711 and 1717 by Chinese lamas instructed by Jesuits in Peking and was until about a century ago the only map of Tibet The identification of Mount Everest on this map is very doubtful A range of great heights is shown at right angles to the actual alignment of the peaks of the region Located in terms of the river valleys, which the lamas portrayed more accurately than the mountains, this range is forty miles distant from Mount Everest Moreover there is no indication that the lamas were aware of an exceptionally high peak in that region Thus, there are no grounds for using the lamas' name of Chomo Lungma for Mount Everest, as Dr Hedin suggests

Attempts to discover a Tibetan name for the mountain have resulted in five names being found Each has merely local use and not one has any general acceptance although the mountain is a conspicuous feature from several parts of Tibet One of these names is certainly Chomo Lungma, but it would appear to have restricted use and to be applied to both Everest and Makalu in fact, it is applied to an area rather than a peak

In these circumstances, there is no justification for displacing the name of Everest It has always been the practice of the Survey of India to use local names when these have been in existence Everest is probably the only departure from this principle but it is a departure that was unavoidable Even if a Tibetan name in general use were revealed, it would be of doubtful value to replace a name that has no[w] become universally known and accepted No po[s]sible benefit could result from such a change

Research at the Mellon Institute during 1930-31

IN his eighteenth annual report to the board of trustees of the Mellon Institute, Pittsburgh, the director, Dr E R Weidlein, has summarised the activities of the institution during the fiscal year ended Feb 28, 1931 The sum of about £160,000 was contributed to the Institute by the industrial fellowship donors in support of scientific research The total amount of money appropriated by companies and associations to the Institute for the twenty years ended Feb 28, 1931, was £1,511,000

Throughout the entire fiscal year 76 industrial fellowships—22 multiple fellowships and 54 individual fellowships—were in operation During the preceding year the number of fellowships was 71 In 1930-31, 140 industrial fellows and 49 assistants held positions on the research staff Sixty four industrial fellowships (17 multiple fellowships and 47 individual fellowships)—three more than on Feb 28, 1930—were active at the close of the fiscal year Nine fellowships are being sustained by industrial associations The industrial research personnel consists of 109 fellows and 31 assistants Thirty one fellowships have been in operation for five years or more, and of this number 18 have concluded more than ten years of work Three (and possibly four) new fellowships will begin operation during the early part of the present fiscal year, as soon as laboratory space is available

According to the report, noteworthy results have developed from the following fellowships air pollution, by product coke, face brick, fertiliser, heat insulation, iodine, nitrogenous resins, organic synthesis, refractories, sleep, and utensil Twelve fellowships completed their research programmes, namely chrome ore, insulating lumber, Portland cement composite glass, yeast, inhibitor, steel treatment, rock products, roofing, fatty acids (uses), oxygen, and face brick Thirteen new fellowships were added to the Institute's roll during the fiscal year, as follows safety fuse, plastic composition, bread, cottonseed products, hydro engineering, abrasives, newsprint, fatty acids (synthesis), shoes, optical glass, commodity standards, and tyre bead

The Department of Research in Pure Chemistry had a productive year and two fellows were added to the staff Twenty two investigational reports have been published since the establishment of this department in 1924 Among the subjects that are receiving research attention are the chemistry of marine plants, cherry gum, gum arabic and quince seed mucilage, and the properties of the sugar acids

The publications by members of the Institute during the calendar year 1930 included 1 book, 5 bulletins, 45 research reports, and 44 other papers Sixteen U S patents and 13 foreign patents were issued to fellowship incumbents The total contributions to the literature for the 19 years ended Jan 1, 1931, have been as follows 16 books, 101 bulletins 573 research reports, 893 other articles and 423 U S patents These publications are listed in the Institute's *Bibliographic Bulletin* No 2 and its four supplements

The commencement of the construction of the Institute's new home is referred to as the most important event during the year covered by the report Early in May 1930 it was decided that, as the present two buildings of the institution are inadequate for the immediate and future needs of its departments and industrial fellowships, a commodious modern structure would be built at the corner of Fifth and Bellefield Avenues, Pittsburgh The excavating work, which was begun on Nov 5 was finished in March and the foundation is now being constructed

The new building, which will be completed in about two years will enable the Institute to expand greatly its research facilities and activities in both pure and applied science The structure which will be in the Ionic style will be built of granite and Indiana limestone, it will be plain but massive, and will be surrounded by 62 monolithic columns The proportions of the building will be approximately 300 ft by 275 ft, and there will be eight working floors

Hydrography of Polar Seas

IN the journal of the International Council for the Exploration of the Sea, for December 1930 (*Journal du Conseil*, vol 5 No 3, p 329), E Kreps and N Verjbinskaya of the Murman Marine Biological Station describe the results obtained on cruises made in the months of March, May, September, and December along the meridians 33° 30′ E and 38 E from the Murman shore to the ice margin The waters showed the typical cycle of the utilisation of phosphates and nitrates by the phytoplankton in the spring and summer months and their regeneration in the winter The phytoplankton was, in this research, estimated by centrifuging an aliquot part of sea water, dissolving the contained diatoms in alcohol, and determining the amount of chlorophyll present spectro photometrically

The region under survey is invaded by branches of the North Cape current of warm Atlantic drift water, the southernmost branch being the Murman current, and the Franz Joseph branch being in the north An interesting difference between the cycle of events in the cold polar waters and that in the warmer Atlantic water was brought out In May, in the cold Arctic waters, an outburst of diatom flowering had already taken place and the surface waters down to 25 metres showed a decrease in their manurial salt content, the Atlantic water, however, showed little difference in its content of these salts from the surface to the bottom and there was as yet no sign of diatom growth In September there was little difference between the Arctic and Atlantic waters, the surface layers all being depleted in phosphate and nitrate and the deeper layers rich, but the conditions of phytoplankton production were reversed, the Atlantic surface waters being now rich in chlorophyll and the Arctic waters very poor

It thus seems that the outburst of phytoplankton in the Atlantic water takes place later than in the Arctic waters The actual reasons for this afford an interesting problem In winter complete vertical mixing had taken place and the phosphates and nitrates had been enriched from the surface downwards In 1930 observations made between March 28 and April 11 showed no sign of the vernal outburst in the Arctic waters

With reference to the relative richness in nutrient salts the inshore waters were the poorest the Arctic waters the richest the Atlantic water being not so rich as the cold The maximum winter values for phosphates were in the neighbourhood of 50 60 mgm P_2O_5 per cubic metre In the same journal it is also interesting to read of phosphate estimations made in southern polar seas by Johan T Ruud (*ibid*, p 347), here in places in the Weddell Sea the readings run up to 150 mgm P_2O_5 per cubic metre at the surface

University and Educational Intelligence

CAMBRIDGE.—An election to the Sheepshanks Exhibition for proficiency in astronomy will be held in the present term. Any member of the University under the standing of master of arts or, being a research student, under the standing of doctor of philosophy may be a candidate for the exhibition. The holder of the exhibition is required to engage in astronomical research to the satisfaction of the Council of Trinity College. Candidates are invited to send in their applications, before May 6, to Prof. Stratton, Gonville and Caius College, stating their qualifications and claims and proposed course of astronomical research.

The General Board recommends (a) that a university lectureship in pharmacology be established in the faculty of medicine as from Oct. 1, 1930; (b) that a university demonstratorship be established in the Department of Experimental Psychology as from Oct. 1, 1931.

The following Syndicate has been appointed to consider the medical courses and examinations of the University and their relations to courses and examinations for the degree of B.A.: the Vice-Chancellor, Prof. H. R. Dean, Mr. W. Spens, Sir Humphry Rolleston, Dr. T. S. Hele, Dr. E. D. Adrian, Dr. A. E. Clark-Kennedy, Dr. L. A. Borradaile, Prof. J. T. Wilson, Prof. J. Barcroft, Mr. H. Thirkill, and Mr. H. McCombie.

EDINBURGH.—Members of the University Court, Senatus, and General Council and a large body of students attended on April 22, in the Old College, a memorial service to the late Prof. Lorrain Smith, professor of pathology since 1912 and dean of the faculty of medicine. The service was conducted by the dean of the faculty of divinity, Prof. Curtis; the text was read by the Vice-Chancellor, Sir Thomas Holland; and Prof. Samuel Alexander, of the University of Manchester, paid a tribute to the memory of Prof. Lorrain Smith. Representatives attended from the Universities of Belfast, Manchester, Cambridge, Glasgow, and Aberdeen.

LONDON.—Keddey Fletcher-Warr Studentships, each of the value of £250 a year for three years, have been awarded to Mr. H. W. Thompson, for a study of the chemistry of the methyl- and the chloro-naphthalines, and to Margaret Hill, for the continuation of work in progress on the regulation of the ovary, with special reference to the part played by the hormones of the anterior pituitary body.

THE fourth biennial conference of the World Federation of Education Associations will be held at Denver, Colorado, on July 27–Aug. 2. Of special interest is the health section, which is active in promoting the health of children through the schools of the world. Further information concerning the conference can be obtained from Miss S. L. Jean, 200 Fifth Avenue, New York.

AN election will shortly be made to a Bayliss-Starling Memorial Scholarship, founded by old students, friends, and admirers, in commemoration of Sir William Bayliss and Prof. E. H. Starling. The scholar will be required to follow a course of study approved by the Jodrell professor of physiology at University College, London, involving a training in the principles of, and methods of research in, physiology and biochemistry. Candidates must send their applications to the Secretary of University College not later than Friday, May 15.

A PARTY of representatives of the universities of Great Britain were the guests of the Prussian Government on April 19, at the State Opera House, Berlin. The party has been on a tour of investigation of the German university system. The tour was organised at the instance of the International Relations Committee of the Association of University Teachers. It is the second international tour that has been organised, the first having been to France in 1930. The objects in view are to collect data for a comparative study of university systems and to promote contact and co-operation between academic circles in Great Britain and other countries. Visits to Switzerland and the United States of America are in contemplation. Both in France and in Germany these visits have aroused wide and intense interest among educational authorities, who have received the parties with the greatest cordiality and have offered the fullest facilities for inquiry into every aspect of their activities. There can be little doubt that in publishing detailed reports of these investigations, the Association of University Teachers is performing an important service both to the cause of higher education, especially in regard to university development, and in furthering international understanding and goodwill, and that it may eventually result in the establishment of some permanent scheme of co-operation on the part of the universities of the world, which may create a forum for the discussion of their common problems. The Report on the French University System, based on the 1930 visit to France, may be obtained from Prof. R. Douglas Laurie, honorary general secretary of the Association of University Teachers, University College, Aberystwyth (6d.).

Birthdays and Research Centres

May 3, 1892.—Prof. G. P. THOMSON, F.R.S., professor of physics in the Imperial College of Science and Technology.

An attempt is being made by several workers at the Imperial College to use the phenomenon of electron diffraction as a tool to study the nature of surface layers, particularly those formed in the corrosion of metals. It has been proved that cathode rays, when reflected from a crystalline or microcrystalline surface of known structure, form a diffraction pattern which depends on the crystal structure just like the pattern formed by X-rays. Conversely, the pattern gives information about an unknown structure. The advantage of using electrons instead of X-rays is that the former only penetrate a few molecules deep, and so give information about the surface layer without confusion by the bulk of the solid.

May 7, 1886.—Prof. H. HARTRIDGE, F.R.S., professor of physiology at St. Bartholomew's Hospital Medical College, London.

In conjunction with Dr. Ranyard West, I have been engaged on an investigation of certain aspects of muscular tone. We have found that tetany, produced in animals by the removal of the parathyroid glands, may be temporarily relieved by the administration of the drug curare. Before giving the curare, an animal may be lying on its side with its limb muscles in tonic contraction; about half an hour after giving the curare, the animal may be running or eating in apparent normal health.

Since curare is used as an arrow-head poison for producing paralysis and death, this 'cure' of tetany is a very unexpected phenomenon. We are investigating the matter further, as we hope it may throw light not only on the mode of action of curare but also on the nature of tetany.

eties and Academies.

London

ʊgical S ɔciety, April 1 —**Bernard Smith** The ır-lakes of Eskdale, Miterdale, and Wasdale, ɔerland, and the retreat of the ice during the n Glaciation' From a review of the available ɲce in the north west of England it is concluded the Great Ice Age in Cumberland and the Irish basin comprised at least three main episodes paper is confined chiefly to the second—that of Main Glaciation' The withdrawal of the com Irish Sea and Lake District ice towards the close episode is discussed, and it is concluded that the ɩetween the two ice sheets progressed north Irish Sea ice tending to shrink on one hand s the sea basin westward and north westward, the Lake District ice—breaking up into tongues glaciers—tended to shrink north eastward and d The stages in the formation of the lakes eir deposits are described, and the positions of fronts at different times are indicated Of the s, special reference is drawn to beaches, especi ɔse fringing islands, to normal lake deltas, and ety referred to as 'scale deltas' —**Rev Joseph** The 'one hundred foot' raised beach between and Chichester Prestwich, in 1858, assumed 15 foot raised beach at Brighton is represented 00 foot raised beach west of Arundel Clement seems to accept this identification There is, ', no proof, either of (1) any differential move the general process of elevation, or (2) a fault the two ... that might account for the cy in level... Moreover, the 'rounded , cited by Prestwich as connecting the two of marine material, is almost certainly of ary age It seems safer to assume the presence wo stages of raised beach—a '100 foot' and a ot' beach Clement Reid appears really to sup his view when he is considering the different of the Selsey deposits So also, more recently, J O White Nevertheless, it must be noticed here is, apparently, no ascertained example of 00 foot beach east, or of the 15-foot west, of the Valley

oyal Meteorological Society, April 15 —**W D** er An analysis of the cold front over Egypt on 7, 1929 The usual autographic records of l, temperature, humidity, and pressure at Helio- s and Ismailia were used, with records of the cal temperature gradient at the latter station old air advanced in the form of a wedge with e above the surface of Ismailia, but as a flat on the surface at Heliopolis —**W H Pick** te on the relationship between fog and relative idity The fogs occurring at synoptic hours at ngton during the years 1929 and 1930 are ex- ied and it is shown that the majority of them accompanied by unsaturated air, as determined eadings of the dry and wet bulb thermometers concurrent occurrence of unsaturated air is pendent of the intensity of the fog, even the rity of the very thick fogs being so accompanied **Jameson** Temperature observations on Adam's , Ceylon Observations of temperature made at summit of Adam's Peak, Ceylon, altitude 7360 feet, wenty three days in January and February 1930, discussed and compared with simultaneous ob- ns at Nuwara Eliya, a valley station at 6170 The night temperatures showed the normal e es between a valley and a peak site During la, however, there was a sharp rise of tempera- in the morning, lasting until about 11 A.M, and giving much higher temperatures than might be expected at that altitude This was followed by a steady fall, until the constant night temperature was reached about 6 P M These day temperatures were probably due to mountain winds converging up the Peak in the morning, and forming cloud over it before midday —**S P Wiltshire** The correlation of weather conditions with outbreaks of potato blight The present investigation has been carried out to see if the correlation established by Dutch workers between the weather and blight outbreaks holds good in England, and the results obtained indicate that while the requisite conditions occur more or less regularly before outbreaks, such conditions are not invariably followed by attacks of the disease The fact that outbreaks do not usually occur without the weather requirements being fulfilled, though negative in character, appears to be of value in practice, and in the intensive seed potato growing area of Friesland, where as many as ten sprays may be applied in a year, the service has enabled the grower to wait with some degree of safety for appropriate weather conditions before spraying

Paris

Academy of Sciences, Mar 16 —**L Cayeux** The epigenic origin of the Jurassic dolomites of the Pyrenees The formation of these dolomites is a case of the general problem of the dolomitisation of a limestone —**H Vincent** and **L Velluz** The cryptotoxic properties of the halogen substituted oxybenzoic acids The results of a systematic study of the cryptotoxic properties of the chlorine, bromine, and iodine derivations of salicylic acid Salicylic acid is from two to three times as active as its isomers, and sodium diiodosalicylate possesses 280 times the cryptotoxic activity of sodium salicyl- ate it also possesses antiseptic properties —**C de La Vallée Poussin** Some extensions of the method of *balayage* of Poincaré and on the problem of Dirichlet —**E Mathias** The existence or non existence of lightning *en chapelet* —Thomas Hunt Morgan was elec ... *correspondant* for the Section of Anatomy and Zo ... —**Arnaud Denjoy** Riemann's hypothesis on ... distribution of the zeros of $\xi(s)$, related to the th ... of probabilities —**Paul Lévy** Some theorems ... enumerable probabilities —**G Pfeiffer** The construction of the general operator permuting the intervals of a linear and homogeneous partial differential equation of the first order —**E Kogbetliantz** The summability (C, δ) of developments according to Hermite polynomials —**Henri Mineur** The dynamics of variable masses according to the laws of Newton and of Einstein —**Mme E Chandon** The mean depth of a canal calculated by means of the harmonic constants of two stations —**E Fichot** Remarks on the preceding communication —**L Brillouin** —Elasticity, thermal agitation, and fusion of solids —**Paul Ansiau** The realisation of a mercury vapour pump Description of construction, with a diagram, mode of working, and performance of a mercury vapour pump —**Pierre Auger** and **Mlle Thérèse Meyer** The directions of emission of photoelectrons Experiments have been carried out with the $K\alpha$ radiation of uranium, and the results compared with calculations based on Sommerfeld's theory —**Mlle M Chenot** The phenomena of propagation in ionised gases by discharges of very high frequency —**Constantin Salceanu** The magnetic rotatory polarisation of some higher homologues of the organic fatty acids The acids studied were decanoic, lauric, myristic, palmitic, and stearic Perkin's rule is only true as a first approximation, as systematic differences appear for the higher terms —**Pierre Montagne** The application of a square

diagram to the representation and calculation of the equilibrium in the water gas reaction —**R Wurmser** and **J Geloso** The oxido-reduction potential of solutions of glucose —**L Bull** and **Mlle Suzanne Veil** The kinetic study of Liesegang's rings —**Picon** Pure cerium sulphide Sterba's method, the interaction of cerium oxide and hydrogen sulphide at a high temperature, gives a product free from oxygen provided the temperature is 1500°-1600° C At 1000° C the sulphide still contains 2 per cent of oxygen The pure sulphide melts at 2200° C and is stable at the melting point The reaction with carbon dioxide at 700 C is unusual, $Ce_2S_3 + 4CO_2 = 2CeO_2 + 4CO + 3S$ —**M Bourguel** The formation of an intermediate form in an acetylene transposition The prolonged action of sodium amide at 60°-70° C upon $C_6H_5C \equiv CCH_3$ gives a sodium derivative, from which treatment with dilute acid gives $C_6H_5CH_2C \equiv CH$ and an isomer which does not react with ammoniacal cuprous chloride This isomer absorbs oxygen giving $C_6H_5CO\,CO\,CH_3$, and its composition is undetermined —**Henri Termier** The discordances of the meso and cenozoic series in Central Morocco and the Middle Atlas —**L Eblé** and **J Itié** The values of the magnetic elements at the Val Joyeux station (Seine et Oise) on Jan 1, 1931 The only special point is the clear increase in the vertical component This has now the same value as it had on Jan 1, 1911, after having undergone in the twenty year interval an oscillation characterised by a relative maximum in 1918 and two minima in 1915 and 1926 —**N P Péntcheff** The proportion of krypton and xenon in some Bulgarian natural gases The spectrophotometric method of Moureu and Lepape was used in these determinations The results are in agreement with the astrophysical theory of Moureu and Lepape **Kalé** Contribution to the morphological study of the stem of *Triticum vulgare* —**P Vignon** The teeth of the labrum of certain gasteropods with turbinated shell, and the relations which they may develop with the varices —**Mlle Odette Tuzet** The parabasal apparatus and the dictyosomes in *Reniera simulans* ai *Hymeni acidon sanguinea* —**Maurice Piettre** and is **Celan** The rôle of the different cellular elei its in the mobilisation of the lipoids in the mam uy gland, Donné's corpuscle —**Maurice Lecamp** Experimental duplications of the posterior limbs in the toad *Alytes obstetricans* —**Ch Joyeux** and **J Pieri** The hibernation of the virus of Mediterranean exanthematic fever It is proved that *Rhipicephalus sanguineus* can harbour the virus of this fever during the winter, or for at least the first part of the winter There are indications that the virus is attenuated by this hibernation

GENEVA

Society of Physics and Natural History, Nov 20 —**Arnold Pictet** The existence of two markings in guinea pigs, one dominant, the other recessive In guinea pigs, the marking of the body is dominant in the monohybrid of uniform coloration, whilst the marking of the extremities is simply recessive These two monohybrid systems fit into each other to form a dihybrid system, so that the heredity relations between the uniform fur and the two kinds of markings are governed by a double pair of inheritance factors —**E Bovier** The ammonites of the upper Sinemurian of Champfromier (French Jura) The author gives a list of the ammonites from the Lias which he has collected at Champfromier From these the presence of the three following Oppel zones is inferred *Echioceras raricostatum* zone, *Oxynoticeras oxynotum* zone, and *Asteroceras obtusum* zone He then points out the differences observed between the sections of
British authors and his results, as ‹

Tanganyika to the Cape, especially the country south of the Zambezi—in the ravines running down the sides of the mountains The finest paintings and the surfaces on which a number of pictures are closely grouped one upon another are usually found in narrow gorges through which flow the more important streams The sites in the secondary gorges and on higher ground are less numerous and generally not so rich

Stow's work does not include copies from all the areas in which paintings have been found, nor, as we have said, did he copy all the drawings in each shelter Nevertheless, his selection gives a richly documented view of the rupestral pictorial art of the country in which he worked The fauna figured is abundant and varied All kinds of antelope are there—above all, the eland, which is figured so often as in the end to become stereotyped Elephants are numerous, rhinoceros and hippopotamus rather rare, quaggas, zebra, and giraffe are not lacking, of the smaller animals, baboons, jackals, hares, and boars appear occasionally only, among the carnivores, the lion and the leopard are most frequent In the most recent paintings, oxen, sheep, and dogs, with Bantu herdsmen, take a prominent place and are well rendered The horse, which was introduced in the last century only, is less successful It is occasionally shown ridden by Europeans With the exception of the ostrich and the crane, birds are rare, but there is a number of serpents, principally the python As for fish, tortoises, and frogs, these appear only in the mythological scenes Insects, as well as vegetation, are seen only exceptionally However, it is to be noted, Rhodesia affords a number of examples of trees

Man, both sexes, and alone or in groups, appears in abundance, and engaged in all sorts of activities, hunting, dancing, fighting, running, and the like As a rule, the figures are nude, but some are clothed in skins, generally in recent paintings in which Bantus also appear, as well as domestic animals—some of which are European domestic animals Some of the figures have the head of a bird or a mammal, this occasionally in connexion with the chase, sometimes in connexion with the metamorphoses in which the Bushmen believed No inanimate objects are represented, if those which are being used by the human figures are excepted Nor is there any attempt to represent the landscape, unless this interpretation is to be placed on a number of dots which may be a fold or enclosure Once only a marsh is indicated Here also we must note that, in Rhodesia, marshes, rocks, and rain are represented frequently Some sym are compared by Miss Bleek with those w occur with such frequency in the rock-engra of the Vaal and the Orange River

There can be no doubt, according to Miss I that all these paintings are the work of the B men Fifty years ago the surviving Bushmen claimed them as the work of their race Furth they are not all contemporary While the old pictures of animals are the best, those of m attained greater accuracy as it became necessa to distinguish different races by a more exact sentation of their characteristics

The colours employed by the artists are re all shades, yellow, brown, chocolate (ochre clay), black (charcoal), white (oxide of zinc), r blue or blue-grey (phosphatic nodules from schist), and violet The pigments were ground

Miss Lloyd remarks that in case of superpositi the older drawings are often dark red or yello a fact which she attributes to the more lasti qualities of these colours She has noted t the white of the polychromes tends to dis and that white is not used in the oldest p I cannot mention these observations making considerable reservations, as they part, contrary to facts I have observed my No doubt they are drawn from localities c than those I have visited The subject is c which requires for its complete elucidation a pr longed study, which it has not yet received any case, according to Miss Bleek, blue, rose, a violet are found only in the later paintin Further, Miss Bleek has observed, and herein s is in agreement with me, that red figures are sup posed on black and vice versa The distribution colours in a figure is, as a rule, conventional, l occasionally naturalistic

The sandstone of the shelters, which are not any great depth, is, according to Miss Bleek, m often than not fairly friable and scales readily would add that elsewhere it is far more resista The figures often blend into the background T does not come out in Stow's reproductions, whe the background is conventional There are al paintings in niches apart and on isolated bloc The greater number of the paintings are at medium height The best preserved are fou towards the top, where they are out of the re of the rubbing of cattle Trees and vegeta where there are any, have exercised a pr influence

How old are the most recent of these pai The extinction of the Bushmen may be pl

nety years ago in the region of Queenstown, at ghty near Barkly, and at sixty in the Orange Free te and Basutoland That they knew and under- ood that the subjects painted were scenes in history of their own race is established by the lowing facts Stow showed some of his copies the aged members of a Bushman family They eclared, not without emotion, that one was a epresentation of a dance of their tribe, and they eproduced it with appropriate song accompani- nent In 1870-75, Dr W H I Bleek and Miss C Lloyd, after learning the language of the shmen of whom they were in charge, showed m Stow's drawings, and obtained from them an planation of them and an assurance that they re the work of their race Many of the mythical l mythological explanations which appear here ith the plates are derived from this source and hrow a curious light on Bushman beliefs It was t about this time that Orpen obtained his in- ormation, and it was about 1886 that Maluti, the st artist of the Bushman tribe, was killed at tte Bergen Colonial Native Reserve, when he carrying in his belt little horn pots each con- ning a different coloured paint Naturally, the ushmen of the Kalahari, where there are no ocks, are ignorant of the art, as are also those who ave been able to survive in captivity or in de ising conditions In any case, between 1878-80 id 1910 the folk lore of the race has become quite tinct among the survivors around Prieska

That some of the paintings are not older than le last century is certain There are some which ow Bantus, the date of whose arrival in certain eas can be fixed with certainty There are hers which represent Europeans dressed in the stume of the time of Queen Victoria But it is ident that there are some—and those a consider- le number—which are much older At Invani, ar Queenstown, Stow noted five layers of paint- s superimposed, and as he had learned that the shmen did not cover the work of an artist as ng as his memory persisted, he concluded that is would give an age of about 500 years for the dest of the paintings There are some which e certainly earlier, but Miss Bleek is unable to d any criterion which will establish this as oved fact She is of the opinion that the dis- egration of the rock would not admit of the rvatio of paintings of any very great age es she think it would be po le to rely on lence of degeneration in t art towards , for there are excellent ex iples among st recent paintings, and poor among the most ancient Large polychrome figures of animals are obliterated by monochromes, or the reverse, there are horses among the polychromes, and mono- chromes occur at all stages, although the red and orange, offering greater resistance as they possess more lasting qualities, are among the most ancient

I should like to add a few words on the points raised in the preceding paragraph While it is true that there are certain rocks which disintegrate rapidly, there are others which show as much power of resistance as those of the rock shelters of eastern Spain, which are of palæolithic date, and of which the paintings show much the same ap- pearance of fossilisation as they do in this region There are many among these ancient paintings which can be seen only when they are wet I am, therefore, of the opinion that many are much older than Miss Bleek thinks Even if the white loses its brilliance, it is still there On some of the oldest of the pictorial sites in Rhodesia there are whites, and I have seen them in the Orange Free State and at Queenstown I think that, after long, patient, and widely extended study, it may be possible to arrive at some definite conclusion as to the relative age and chronology of the South African art of rock painting Relying on my ex perience in Europe, I have attempted certain pro visional suggestions based upon what I was a to see during my stay in South Africa I am n the less convinced that the work has still done, and that it will be a long business F I am sure that Stow's reproductions for t part belong to a relatively late stage—perha indeed, very late The investigation would have to proceed by the study of large natural regions, rather as Mr Burkitt and, more recently, Dr L Frobenius have done

Miss Bleek has devoted considerable space to the Bushmen race, the only race she considers to have a gift for pictorial art Before the arrival of the European, they were bounded on the west by the Hottentot and on the north and east by the Bantu races, with whom they were engaged in warfare Although they belonged to one race, they were differentiated in their languages, their beliefs, and their customs I would add that, so far as is indicated by the fine models from life in the Cape Town Museum, they showed appreciable differences in physical character For example, steatopygia does not appear in the southern group Miss Bleek affirms positively that there were not only several languages, but also several groups of languages, which does not seem to fit in with a strict unity

The Bushmen lived near water-holes, in groups

sets out to give a clear explanation of the implications underlying the new theory This he does, not merely by the routine of mathematics developed for the solution of problems, but by a detailed discussion of important *Gedankenexperimente* which provide good illustrations of the operation and range of the 'uncertainty principle' and bring out very clearly one of the main points of philosophical interest associated with the new ideas This is that it is necessary either to abandon the classical conception of causality in space time descriptions of microscopic phenomena, or to retain the principle of causality at the expense of the space time description, substituting for it a mathematical description not in space and time

This book should be read by all interested in modern physics, especially as it is written by one of the pioneers of the new theory

(3) These two volumes by Prof Léon Brillouin on the quantum theory are written with a lucidity of expression which is characteristic of the author, and they contain a mass of detail on statistical theories about which there has recently been nothing less than a revolution in thought

The earlier chapters of the first volume are devoted to a consideration of the classical theory of radiation and to the old form of the quantum theory Apart from the intrinsic value of the subject matter, it is an excellent introduction to the newer work, and is written in the light of the recent advances From these earlier chapters we pass to the recent developments due to Bose, Einstein, Fermi, and Dirac with applications to radiation and to the theory of gases

In the second volume the first chapter deals with the interesting examples afforded by the study of electrons in metals to the new theory The modern theory of electrical and thermal conductivity, of the Peltier and Richardson effects, and of contact potential are among the fascinating problems treated One chapter is devoted to the evaluation of electronic mean free path, and in another the treatment of the degenerate electron gas is given

A glance at the table of contents will show that these are merely a few examples of the subject matter The present position of the modern electron theory of metals is such as to awake optimism concerning its future The treatment of these problems by the new methods should arouse the interest of the teacher, who can confidently introduce them to his students, and as advance along these lines is rapid, the research worker must keep abreast of these developments For both purposes these volumes are to be recommended

Our Bookshelf.

Ethnologischer Anzeiger Jahresbibliographie und Bericht über die völkerkundliche Literatur Herausgegeben von M Heydrich Band 2, Heft 4 Pp 129 200 (Stuttgart E Schweizerbart'sche Verlagsbuchhandlung (Erwin Nagele) G m b H, 1930) 9 40 gold marks

IN the bibliography of which this is a part, it is proposed to cover the literature of ethnography, including folk lore and religion, from 1924 to 1930, in three volumes Bibliographical work in anthropology, now more than ever, is a serious undertaking Here, for example, in dealing with one section of the science only, though certainly the largest, there are more than a thousand entries to cover part only of Africa—from "Lequeux" to the end—and a part of Europe—down to "Pallin" under "Finno Ugrian Peoples", near, though not quite at, the end of the main heading Even within these limits, the entries are not complete—English literature is not too well represented, especially under Africa, and the years 1926 and 1927 only are covered A few entries are archæological rather than ethnographical A very useful feature of the publication is that some less accessible contributions to anthropological literature, especially those appearing in the eastern European languages, are abstracted

Each main heading of the bibliography has been entrusted to one or more experts for purposes of compilation Bibliographical work, however, in anthropology more than in any other science (except perhaps zoology), demands international co operation if it is to be anything like complete There are at present in existence a number of bibliographies For the most part, each one deals with some single aspect of the science But even so, these specialist bibliographies overlap at times, and none of them is complete Since the International Catalogue of Scientific Literature ceased publication in 1914, no attempt has been possible in the direction of a full and adequately complete bibliography of anthropology as a whole It is a matter which might well engage the attention of the Committee for Intellectual Co-operation under the League of Nations

Biology for Schools a Textbook suitable for School Certificate and similar Examinations By Dr E R Spratt and A V Spratt (School Examination Series) Pp viii + 403 (London University Tutorial Press, Ltd, 1931) 4*s* 6*d*

THE demand for school text books of biology is still small when compared with that for text-books in almost any of the generally recognised subjects of the curriculum It is then a matter for compliment to the publisher who can produce a book of more than four hundred pages, well bound, well printed, and containing an average of more than one illustration per page, for the modest price of 4*s* 6*d* The authors have compiled a very considerable amount of useful information, and many of the original drawings (especially those of floral structure) are admirably executed

At the same time, there appears to have been

little time or opportunity for revision of the text, so that a number of corrections will be required in a subsequent edition There is no acknowledgment, in the preface, of borrowed illustrations, and though a certain number of these are acknowledged in the text, there remain a few which are not For example, Fig 19 is scarcely distinguishable from that of the same subject (mustard seedlings) by Sachs Fig 196 bears an equally close resemblance to that of the lungs in Thornton's "Physiology", while in Fig 215 one recognises the old familiar spotty frog from Sir Arthur Thomson's "Outlines of Zoology" Among the original drawings which will require correction are Figs 168, 221, 232, 245, and 301 A number of errors also creep into the text For example, the experiment on p 36 concludes with the word "absorbed" where "transpired" is presumably intended, the description (as well as the illustration) of the trout on p 232 will give pain to any honest angler—"scales of calcium carbonate, commonly called chalk", is only part of the heresy These lapses will, however, be easier to rectify than a tendency which runs throughout the book to hurry from description to description, without a pause to consider or to summarise the broad principles involved

The Practical Dog Book with Chapters on the Authentic History of all Varieties hitherto unpublished, and a Veterinary Guide and Dosage Section, and Information on Advertising and on Exporting to all parts of the World, a Comprehensive Work dealing with the Buying, Selling, Breeding, Showing, Care and Feeding of the Dog By Edward C Ash Pp xxxii + 343 + 44 plates (London Simpkin Marshall, Ltd, 1930) 21*s* net

IT is four years since we had the pleasure of reviewing Mr Edward Ash's magnificent and encyclopædic work, "Dogs their History and Development", and it is a pleasure to receive another work on the same subject from his able pen

The present book covers, to a great extent, the same ground as his former one, but in a very much shorter and more concise manner In addition to a series of excellent descriptions of the various breeds of to-day, with their histories, there are sections which deal with the care and management of kennels in general and their inmates, both in sickness and in health For those taking up dog-breeding as a hobby or a career, there are invaluable chapters dealing with the transport and export of dogs to foreign countries, with quarantine regulations at home and abroad, and the latest possible information regarding the showing of dogs in every country in the world

The book is profusely illustrated with a series of beautiful plates These fall into two groups which form an interesting and instructive contrast One group consists of the dogs of yesterday, which include not only the dogs of the past century but also dogs from the very beginning of things The second group is composed entirely of the best specimens of the dogs of to-day

Mr Ash has collected together in this work a thousand and one items of information about dogs in general, which should be of the utmost value to anyone concerned in the breeding and exhibition of these animals To the dog lover and student of history, also, the book should be of the greatest value and interest

The Origin and Growth of Religion Facts and Theories By Prof W Schmidt Translated from the original German by Prof H [illegible] Rose Pp xvi + 302 (London Methue[illegible] Co, Ltd, 1931) 15*s* net

IT was a happy idea that urged Pater [illegible] write this manual for the comparative [illegible] religions, and a still happier one that pr[illegible] Prof Rose to translate it into English [illegible] based on notes for a year's course of the auth[illegible] lectures and covers the history of the subje[illegible] sketches the various theories, movements, an[illegible] schools, and gives a brief account of the religions in the order of their appearance A book of this kind was badly needed, especially for students in England, where ideas about method are apt to be a little nebulous, and where, perhaps, too little attention has been paid to development in theory on the Continent

Pater Schmidt has based his exposition on his great work "Ursprung der Gottesidee", still in course of publication, and his criticism, especially of Tylor and the English animists and pre animists, is orientated in accordance with his views on the priority of the belief in 'high gods' He is less than respectful to the English 'diffusionist' school It is evident that the author is not fully acquainted with the movement of anthropological thought in England and does not understand the various ways in which it develops The tone of his criticism of Tylor's alleged silence on the subject of 'high gods' is unworthy While his health lasted, Tylor neither ignored nor attempted to burke criticism of his views, but he did not rush into print Unfortunately, the same tone appears, if not so pronounced, in Father Schmidt's criticism of 'Protestant' anthropologists The only appropriate reply is a *tu quoque* In neither case is the cause of science advanced Some of the excellent notes added by Prof Rose here serve to palliate the defects

Intermediate Mechanics Dynamics By D Humphrey (Longmans' Modern Mathematical Series) Pp x + 382 (London, New York and Toronto Longmans, Green and Co, Ltd, 1930) 10*s* 6*d*

THE author of this book has set out to fill, in the case of dynamics, the gap that often exists between the normal senior school course and scholarship work in a subject, and he has succeeded admirably, though, in view of the fact that he does not hesitate to use the methods of the calculus whenever they are helpful, the detailed proof that 60 m/hr = 88 ft/sec seems somewhat outside the scope of the book The arrangement is generally good, and the argument clear, the examples are plentiful and well graded, in many cases being accompanied by excellent notes as to appropriate methods or special difficulties

Letters to the Editor

[The Editor does not hold himself responsible for opinions expressed by his correspondents Neither can he undertake to return, nor to correspond with the writers of rejected manuscripts intended for this or any other part of NATURE *No notice is taken of anonymous communications]*

C[illegible] Nature of Certain Potato Viruses of the Mosaic Group

[illegible] some experiments on the transmission of a [illegible]osaic virus to tobacco revealed the curious [illegible]t needle and aphis (*Myzus persicæ*) inoculation [illegible]tively, from the same mosaic affected potato [illegible]t, produced in tobacco symptoms characteristic [illegible]he method of infection[1] The disease produced by [illegible]e needle has since been shown to be a complex, the [illegible]onstituent viruses of which for the sake of clarity will be referred to as x and y, where x represents the virus which forms in tobacco double concentric rings with a central spot hereinafter referred to as 'ring spot', and y represents the aphis borne virus the symptoms of which take the form of a darkening of the green colour of the tissues along the veins

This phenomenon has formed the basis of further studies carried on since that time, and the following facts which have been elucidated seem worthy of record By the development of a technique of virus isolation from a complex within the living plant much evidence has been accumulated that certain potato viruses of the mosaic group are not single entities but are composite in character This is true of the following, among others—a mosaic from Arran Victory potato a crinkle from Myatt's Ashleaf, a streak carried without symptoms by Up to date, and a streak also carried by Dr Vernon All these diseases have been separated into their constituent viruses by means of the technique which will now be briefly outlined

The methods of virus isolation used in these studies fall into three groups, and separation was effected in the following ways

(1) By utilising a selective relationship which exists between the aphis vector *Myzus persicæ* and the tobacco plant

(2) By the use of what may be called 'filter' plants A comparative study of the host range of the single virus (y), isolated by means of the insect and of the virus complex ($x+y$), revealed the fact that there were several plants which were susceptible to the ringspot virus (x) but were resistant to the aphis transmitted virus (y) This fact suggested the possibility of using certain of these plants as filters, and experiment has shown that passage of the whole complex ($x+y$) through such plants removes the aphis carried virus (y) That the virus y is actually removed by this process is shown by the analysis and synthesis of the complex frequently carried out, and by the fact that the aphis cannot pick up the virus y from a ringspot resulting from passage of the complex through one of these filter plants

It should perhaps be pointed out that successful filtration by means of these plants is dependent upon the needle scratch method of infection, grafting transmits the whole complex Examples of plants susceptible to the virus y isolated by means of the aphis are *Hyoscyamus* sp , tomato, and *Solanum nigrum*, and of the 'filter' plants resistant to this virus, *Datura stramonium* and *Solanum dulcamara* among others All are susceptible to the ringspot virus x

(3) By taking advantage of the unequal rates of movement of the constituent viruses within the plant host (*a*) At the moment of development of primary symptoms in the young plant inoculated with the virus complex (*b*) In the ageing plant

By means of this technique it has been possible to analyse in the tobacco plant the virus complexes into their constituent viruses and then to synthesise them Thus, needle inoculation to tobacco from a streak carrying Up to date potato produced a virulent disease characterised by gross lesions and severe necrosis of the veins with no sign of rings, while aphis transmission from the same plant produced in tobacco the disease y, with the characteristic darkening of the green colour of the tissues along the veins On passage of the necrotic complex through one of the filter plants referred to back to tobacco again, the disease took on a ringspot form with numbers of clearly defined double concentric rings, each with a central spot, there was no general necrosis The primary symptoms of this disease take the form of double rings upon the inoculated leaf Now, to a number of tobacco plants showing this ringspot was added the virus y, which had been isolated from the complex by means of the aphis After the usual incubation period the primary symptoms peculiar to the aphis transmitted virus (y) appeared, following rapidly upon this, the rings lost their regular outline, became filled up and degenerated into irregular necrotic lesions, while a severe necrosis of the veins developed In a short time the symptom picture was identical in every respect with that of the necrotic disease before the separation had been effected Further passage through the filter plants again produced the ringspot disease, while the addition to this of the aphis carried virus (y) once more restored the virulent necrotic picture

While the majority of the diseases studied are shown by these methods to contain two constituent viruses, there is evidence of a third constituent occurring notably in a streak and a crinkle There are also certain cases where only one virus can be isolated, at all events by the present technique, and here it is reasonable to suppose that the disease is a single entity

As regards the question of the non transmission by the aphis, of the ringspot disease produced in tobacco by needle inoculation with these potato viruses, the obvious explanation is that the aphis is the selective agent and picks up one constituent only of the complex There is however, some evidence which suggests that this is not the correct explanation, but that the tobacco plant itself plays a part as the selective factor It is hoped to settle this question during the coming season

Finally to avoid confusion, it is necessary to state that the ringspot diseases referred to here are quite distinct from one or more ringspot diseases which affect the tobacco plant in Nature[2] There appears to be no record of the experimental ringspots and necrotic diseases, here dealt with, affecting tobacco in Nature, a fact probably connected with the selective relationship existing between aphis vector and tobacco plant

It is of interest to record that Valleau and Johnson, in a paper recently received,[3] have also suggested the possibility that *Datura stramonium*, one of the 'filter' plants used in these studies, is resistant to a disease in tobacco called 'veinbanding' by Valleau This veinbanding occurs naturally in the tobacco fields of Kentucky and is presumably identical with the aphis-borne virus (y) originating in potatoes

It is evident that future work upon these potato virus diseases must take cognisance of their composite nature

Anomalous X-Ray Diffraction Intensities

THE accompanying photographs (Fig. 1) show an interesting example of a case where the relative intensities of the lines in any X-ray spectrum may vary without a corresponding change in atomic arrangement. They are Debye photographs of chromium plated wires obtained under different conditions of electrodeposition. It is seen at once that the intensity of the middle line, the (200) reflection, in comparison with that of the other two lines, the (110) and (211), is as strong as normally it should be in the top photograph. In the second photograph it has become relatively weak. In the bottom photograph it has disappeared entirely.

These intensity changes could be explained in various ways if foreign atoms capable of scattering

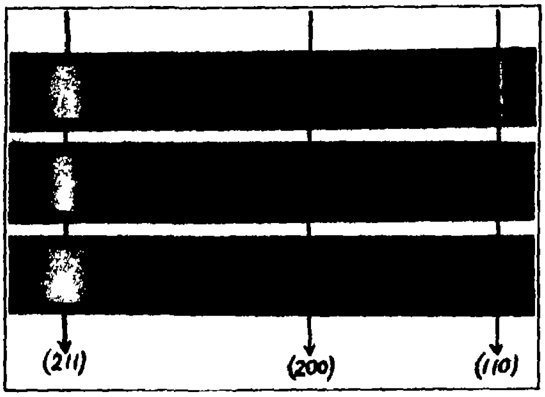

FIG. 1.

X-rays were present to any extent in the deposits. The point of this case, however, is that the metal is apparently free from such impurities. Photographs taken on larger films failed to reveal any appreciable orientation of the grains. The presence of lattice distortion which also might cause the effect, was considered unlikely because the values of the spacings were found to be constant and equal to those usually accepted for chromium.

The probable explanation follows from the work of Laue on X-ray reflection from crystals of a sub-microscopic order of magnitude. The excessive breadth of the lines in the photographs shows that the deposits are composed of such very small crystallites. If those crystals are shaped haphazardly and do not exhibit a preferential habit, all the lines should be broadened in the regular way required by Laue's equations, the broadening being normally larger as the glancing angles increase. But if a majority of the crystals develop a particular form, a flat plate-like shape, for example, or a needle-like shape, then certain sets of planes contain fewer reflecting components, and the resolving power of those planes, in comparison with the others, will decrease until in time they will not produce a spectral line of any degree of visibility. This apparently is what has happened in the case of the (200) line in the photographs. The relative intensities are influenced by the shape of the crystallites.

It is interesting also to note that the type of chromium plating which showed the above effect appeared to be the one characterised by a brilliant lustre. The grey matt type of deposit gave a normal intensity distribution. The full results of the X-ray study of chromium deposits it is hoped to publish elsewhere.

Finally, in view of the fact that the effect occurs with a pure substance, it would seem that the deduction of atomic structure from the relative intensities of the lines on a powder photograph, when the material is in a fine state of subdivision, must be attended with one more complication.

Properties of Dielectrics in Electric Fields

THE issue of NATURE of Jan. 3 contained a letter from Mr. A. Morris Thomas, of the British Electrical and Allied Industries Research Association, in which, while agreeing generally with the principles in my letter in NATURE of Nov. 22 last, he pointed out that the term 'permittivity' is frequently used now instead of 'dielectric constant'.

I was not unaware of this when writing originally, but the term 'permittivity' was proposed by Heaviside before the electrical nature of matter was discovered, and while answering his immediate purpose, it suggests that the action of the field is through the dielectric, while modern knowledge shows that it is directly on the opposite charges constituting the molecules of the dielectric.

Again, modern work shows also that what is called 'capacity' may arise from at least three different causes, which cannot properly be all comprehended under one term, except for special purposes. In two communications to the *Phil. Mag.* (May 1924 and Jan. 1926) I showed that Maxwell's law was true in the case of 11 out of the 19 non-metallic elements of which the value of ϵ was known, including those most important, and that the same almost certainly would apply to, at any rate, 6 of the remainder. The greatest deviation from equality was about 10 per cent.

On the other hand, for many substances, compounds formed of the above elements, the relative values of ϵ and N^2 widely differ.

As to this, it is now generally accepted that atoms and molecules can be divided into two classes.

(1) *Non-Polar.*—In this class, in an outside field there is repulsion of the nucleus and attraction of the electrons but no tendency to orientation. Debye calls this the 'distortion', it is small and any dissipation of energy accompanying it is small also. It agrees approximately with the square of the refractive index.

(2) *Polar.*—In numerous cases the positive and negative charges of the molecules are not symmetrically situated in an outside field: thus, in addition to distortion, they have a moment and tend to be rotated and oriented in line with the field. The capacity of the system is thus increased. This type of capacity, unlike the distortional form, is affected by change of temperature, falling as the temperature is raised and also by increase of frequency.

Both these forms of capacity are due to direct action between the field and the mass of the molecules of the substance acted on. There is, however, a third form of capacity. Ions usually exist in small quantities in dielectrics and constitute polar molecules of the strongest type, with the addition that one pole is stronger than the other; thus, besides orientation, there is a direct pull on the stronger pole of the ion in the direction of the opposite electrode of the field. Thus the capacity of the system is again increased, and at low frequencies this increase may be very large.

In this latter form of capacity the action of the field is on inclusions of electrolytic type, the molecules of which are scattered through the dielectric, and not on the mass of the molecules of the dielectric itself,

as in the two former cases Thus measurement of capacity at a given frequency may contain all the above components In any case, by drying or purification, it is necessary to get rid of, or reduce to a small percentage, the third form of capacity before the other two can be confidently isolated

For technical purposes it is often immaterial to distinguish between the first two forms of capacity, provided the third form can be reduced sufficiently far But measurement and separation of the first two forms is opening up a new chapter in the study of the attributes of non metallic matter itself

The connexion between the properties of matter in an outside field and its other physical properties, however, is not directly through the specific capacity or permittivity, but through the attraction set up between the field and the dielectric, as the result of which the energy is stored, the relative value of which was shown by Boltzmann to be equal to $\frac{\epsilon - 1}{\epsilon + 2}$

This value must again be corrected for the molecular attraction, which should then be a fairly direct measure of the interatomic attraction after allowance is made for polarity

At present there is no suitable name for this important quantity, which is closely connected with cohesion and other physical properties of matter (see the above *Phil Mag* communication, etc), nor for the other forms of capacity mentioned above The time is arriving when it is very desirable that the whole subject of dielectric nomenclature should receive consideration

This letter is rather belated , but I have been unwell and unable to take up the correspondence sooner

The Electrical Layers of the Atmosphere

PROF MILLIKAN has recently directed attention to a remarkable property of cosmic rays, in his presidential address to the American Association for the Advancement of Science, at Cleveland [1] He observed that "somewhere in the atmosphere below a height of 15 5 km the intensity of the ionisation within a closed vessel exposed to the rays goes through a maximum, and then decreases "

Unfortunately, Prof Millikan did not connect this behaviour with other data which appear to be closely associated with it In 1925 I directed attention to the fact that three different phenomena pointed to the conclusion that the atmosphere consists of two layers [3] These zones can be distinguished

(1) *Electrostatically*—the negative zone lying above the positive one

(2) *Optically*—at sunrise and sunset when the air is very clear and the observer is situated at least 2½ kilometres above sea level

(3) *Thermally*—the stratosphere or zone of uniform vertical temperature lying above the troposphere or zone in which the temperature falls with increasing height

It appears from Prof Millikan's data that there is still another phenomenon, (4) *the absorption of cosmic rays*, that points to the same conclusion

It is surely time that geophysicists and meteorologists seriously considered these phenomena In central Europe the dividing layer is situated at from 7 km to 12 km above sea-level, judging from thermal measurements in winter and summer respectively The most probable explanation appears to me to be that

(1) Cosmic rays cause ionisation of the air most readily where it has attained a certain pressure

(2) The movements of the gaseous ions result in gaseous diffusion potential layers, analogous to the liquid potential layers in electrolytes studied by Nernst, the light negative ions rising above the slower and heavier positive ions

(3) A state of electrostatic strain is set up between the layers, and where sufficiently violent local vertical movements lead to engulfment of portions of the upper zone by the lower, negative thunder clouds surrounded by a concentrated positive sheath may be observed [3]

The ozone in the air may very possibly be formed in the region of maximum absorption of cosmic rays, since its concentration in the neighbourhood of mountain peaks exceeds that at sea-level [4] The Heaviside layer of the wireless expert has been placed so much higher than the junction of the two zones (85 95 km) that it seems possible that it corresponds to the position of maximum conductivity in the negative zone

Disease in Nature

IN the discussion in NATURE of April 25 between Mr Ramsbottom and a reviewer, on the occurrence of disease among animals and plants in Nature, one factor appears to have been ignored, and that is the drastic operation of natural selection in weeding out not merely diseased individuals but also any that carry a weakness reducing their fitness to their environment When the reviewer argues that parasitism may not be a disease but only an "innocuous *modus vivendi* ", is he not begging the question ? Relatively innocuous parasitisms persist just in the proportion that the parasite does not enfeeble the host, but no distinction of kind can be made between them and definitely lethal diseases Animals or plants carrying a 'disease', that is, some lowering of the normal vitality, whether genetic, parasitic, or environmentally caused, are so promptly and thoroughly eliminated that examples will be observed very rarely, because such a very small proportion of individuals of any species are closely examined We hear, for example, of grouse disease because so many thousands of grouse are shot each year What about rinderpest and East Coast fever ? They have taken heavy toll of African game without any intervention of man

Man interferes with Nature by taking off the pressure of selection Our civilisation prides itself on rearing as many as possible of the children born, and from this alone follows the prominence of disease and the relative low ratio of human beings possessed of "exuberant positive health " A native tribe in Central Africa would strike the ordinary observer as exuberantly healthy , the medical officer in close touch with them would tell a different story

So far as my own observation goes, of plants perhaps more than animals, disease certainly exists in Nature if you look closely for it, but the individuals affected are so immediately suppressed that cases rarely fall under observation Let me give a parallel which avoids the question begging term 'disease ' A given species of plant in a certain district may seem to be true to type and free from variation , but bring it into cultivation and grow on all the individuals, then variations immediately disclose themselves Baur has shown

with *Antirrhinum* that the type from a given locality which, to judge from herbarium specimens, has remained constant for half a century, is yet heterozygous and begins to segregate so soon as seedlings are grown on without natural selection In Nature, the homozygotes which are produced every generation would seem to fall below the heterozygotes by just that little which ensures their elimination under competition

DISEASE is a point of view When one organism is living in association with another, the former at the expense of the latter, the balance of metabolism in the latter is always disturbed The latter may be called diseased while the former is happy in having a plentiful supply of food without much exertion In Nature such association is constantly going on A certain system ceases to exist while another comes into being as a consequence In calling Nature 'healthy' or 'diseased' we are projecting the human point of view into its operations It seems to me more profitable to try to consider Nature without being influenced by human prejudices

S MAULIK

Evolution of the Occipital Condyle in the Vertebrata

THE origin of the occipital condyles of the skulls of vertebrata has not so far been elucidated They are separate elements from the occipital arch and are ultimately superimposed on the latter, except in fish The occipital arch is the hinder limit of the skull, and the arch which is the beginning of the vertebral column may be termed the atlas, though it is not homologous in Amphibia and Amniota Between the occipital region and the atlas there is an intervertebral body which acts as a buffer An intercalated arch is present on the dorso lateral sides of this intervertebral body, the existence of which was not previously known, this arch is not complete dorsally and does not enclose the spinal cord, the nerve, spinalis I, passes through or over this intercalated arch

In fish, the limbs of this intercalated arch lie on the sides, a little above the level of the intervertebral body, so that when a strand of migratory connective tissue cells divides each of the limbs into two parts, those look like zygapophyses between the occipital arch proper and the atlas arch proper The anterior portion of the intervertebral body, after the division, fuses with the occipital arch to form the occipital condyle It is concave, as the vertebræ of the fish are amphicœlous

In Urodela, the intercalated arch lies almost at the same level as the intervertebral body, and when the division of the two limbs of the intercalated arch gives rise to the two condyles, the intervertebral body, instead of being divided, fuses with the anterior end of the atlas, thus forming the so-called odontoid process of the Urodela In Anura, the intervertebral body, unlike that of Urodela, becomes divided and one part fuses with the atlas and the other part fuses with the occipital region, in consequence of which there is no formation of an odontoid process

In all Amniota, the limbs of the intercalated arch lie at the sides, a little below the level of the intervertebral body In reptiles, the anterior part of the intercalated arch, which becomes divided from the posterior part, gives rise to the lateral portion of the occipital condyle, while the intervertebral body fuses entirely with the skull to form the median portion of the occipital condyle Thus arises the single elliptical occipital condyle The formation of the occipital condyle of birds is almost like that of the reptiles In mammals it is almost like that of Anura In all Amniota, the atlas vertebra has undoubtedly no centrum, but the ventral (anterior) arch completing the floor of the atlas ring is derived from the posterior portion of the intercalated arch, and not from the basiventralia as has been maintained by previous authors

In reptiles and birds, according to the generally accepted view, the intercentrum represents the united basiventralia Now, if the centrum of the atlas vertebra fuses with the axis centrum to form the odontoid process, we might naturally expect that the intercentrum belonging to the atlas vertebra should either remain with the dorsal (posterior) arch of the atlas ring or should fuse with the odontoid process of the axis, and in consequence the latter should have two intercentra instead of one, as is actually found in the dried vertebra of the adult If that be the case, the lower (anterior) portion of the atlas ring cannot be the basiventral element, although it has been generally regarded as such The details of this investigation will be published later

Nitrogen Distribution in Kingston Cheese-Ripening

A STUDY is being made of the nitrogen distribution in Kingston cheese ripening For the determinations, methods evolved and employed by Orla Jensen, by Barthel, and by others have been drawn upon In addition, a departure has been made in the applying to this study of the method developed by Wasteneys and Borsook for the fractional analysis of incomplete protein hydrolysates Determinations were carried out on cheeses of the same 'make' from the day of making to the ninety eighth day of ripening at intervals defined

The method of Wasteneys and Borsook has been applied to the study of nitrogen distribution in Kingston cheese ripening with pronounced success Results obtained when employing the methods of Orla Jensen and of Barthel may now be complemented and illuminated for by the application of the Wasteneys and Borsook method can be defined the nature and the amount of the specific protein decomposition fractions—proteose, peptone, and subpeptone—formed as the ripening of the cheese proceeds Particularly striking is the finding that the difference in the results of the amido nitrogen determinations and the amino nitrogen determinations can be explained when interpreted in the light of data secured by the application of the method of Wasteneys and Borsook The amide nitrogen curve coincides with the subpeptone nitrogen curve, and the amino nitrogen curve is seen to superimpose itself upon the curve depicting the sum of the subpeptone nitrogen and the peptone nitrogen

In the light of the nitrogen distribution in Kingston cheese-ripening, the work of Wasteneys and his co-workers on pure proteins and specific enzymes, the classification and definition of the proteases by Willstätter, Waldschmidt Leitz *et al*, and data appearing in a study of the casein splitting abilities of certain lactic acid bacteria in chalk milk culture and of studies on the sugar-fermenting abilities of certain lactic acid bateria as influenced by defined nitrogen sources, we suggest that at the beginning of the ripening of the cheese the protein hydrolysis is of a peptic like nature, and that this peptic-like proteolysis is to be

attributed not only to the action of the rennet, but also, as our papers about to appear will show, to the elaboration of a peptic like enzyme by certain lactic acid streptococci Even within the first twenty four hours of ripening, the amount of subpeptone appearing suggests that associated with the peptic like action is a tryptic like action—a conjecture that again in the light of our cultural studies on certain other lactic acid streptococci is not without merit

Subject to qualification as further data on the nature of specific enzymes may appear, the results of our study show that after the first few hours of ripening, the proteolytic breakdown in the ripening of Kingston cheese is of an associative peptic tryptic like nature

This study of nitrogen distribution is one of a series on cheese ripening which is provided for by a research fund established jointly by the Empire Marketing Board and the University of British Columbia A detailed account of the experiments will appear shortly in the *Journal of Dairy Research*, Cambridge

Insect Remains in the Gut of a Cobra, *Naia tripudians*

THE accompanying photograph (Fig 1) shows the remains of insects belonging to three orders namely, Rhynchota (Heteroptera Pentatomidæ), Coleoptera, and Hymenoptera (Formicoidea), found in the gut of a cobra, *Naia tripudians*, brought to us in November 1928 The cobra, which was the black variety with no markings on the back of the hood but with white

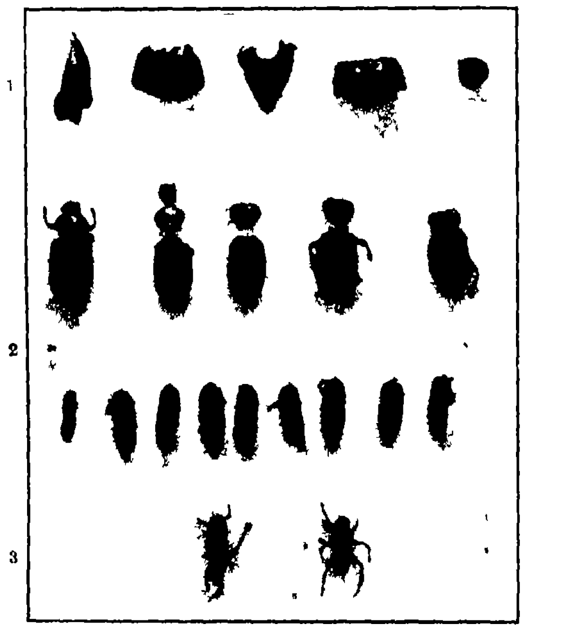

FIG 1

patches on the throat, was captured at Banting, in the vicinity of Kuala Lumpur, Selangor, F M S It was not a large specimen, since it measured only 3 ft 7½ in in length

So far as it has been possible to ascertain, records of insects having been devoured by snakes do not appear to be abundant, the only other two which have come to our notice being that of "a small ruddy beetle" found in the gut of *Tropidonotus stolatus* (Wall and Evans, *Journal Bombay Nat Hist Soc*, vol 13) and of a locust (the species not stated) eaten on one occasion by *Echis carinata* (Wall, *id*, vol 18)

The parts of the pentatomid comprise a right hemielytron, pronotum, sternum, scutellum, and pygophor The ants are ponerines and are capable of inflicting a nasty sting

We are indebted to Dr T A Buckley, Forest Department, S S and F M S, for assistance in preparing the photograph

The Beginning of the World from the Point of View of Quantum Theory

SIR ARTHUR EDDINGTON [1] states that, philosophically, the notion of a beginning of the present order of Nature is repugnant to him I would rather be inclined to think that the present state of quantum theory suggests a beginning of the world very different from the present order of Nature Thermodynamical principles from the point of view of quantum theory may be stated as follows (1) Energy of constant total amount is distributed in discrete quanta (2) The number of distinct quanta is ever increasing If we go back in the course of time we must find fewer and fewer quanta, until we find all the energy of the universe packed in a few or even in a unique quantum

Now, in atomic processes, the notions of space and time are no more than statistical notions, they fade out when applied to individual phenomena involving but a small number of quanta If the world has begun with a single quantum, the notions of space and time would altogether fail to have any meaning at the beginning, they would only begin to have a sensible meaning when the original quantum had been divided into a sufficient number of quanta If this suggestion is correct, the beginning of the world happened a little before the beginning of space and time I think that such a beginning of the world is far enough from the present order of Nature to be not at all repugnant

It may be difficult to follow up the idea in detail as we are not yet able to count the quantum packets in every case For example, it may be that an atomic nucleus must be counted as a unique quantum, the atomic number acting as a kind of quantum number If the future development of quantum theory happens to turn in that direction, we could conceive the beginning of the universe in the form of a unique atom, the atomic weight of which is the total mass of the universe This highly unstable atom would divide in smaller and smaller atoms by a kind of super radioactive process Some remnant of this process might, according to Sir James Jeans's idea, foster the heat of the stars until our low atomic number atoms allowed life to be possible

Clearly the initial quantum could not conceal in itself the whole course of evolution, but, according to the principle of indeterminacy, that is not necessary Our world is now understood to be a world where something really happens, the whole story of the world need not have been written down in the first quantum like a song on the disc of a phonograph The whole matter of the world must have been present at the beginning, but the story it has to tell may be written step by step

Rotational Constants of the Iodine Monochloride Molecule

OUR analysis of the rotation structure of the iodine monochloride absorption bands is now sufficiently advanced to permit of a fairly precise determination of the molecular constants. The region 6482–6837 A. has been measured on plates taken in the second order of a 21 ft. concave grating, and practically all the lines have been allocated to series. The strongest bands in this region are $v''=1$, $v'=8$-12; some bands belonging to the $v''=0$ and $v''=2$ progressions are also present, and there are of course two complete systems, a strong one due to ICl^{35} and a weaker one due to ICl^{37}. The figures given in the accompanying table refer to the former only.

	B_e	B_e''	α	α''	I_e	I_e''	r_0	r_e''
Cl_2	0.162 cm.$^{-1}$	0.2429 cm.$^{-1}$	0.003 cm.$^{-1}$	0.0017 cm.$^{-1}$	170 × 10^{-40} gm. cm.^{2}	113.7 × 10^{-40} gm. cm.^{2}	1.21 A.	0.988 A.
ICl	0.0869	0.1141	0.00115	0.00104	318.4	242.4	2.643	2.306
I_2	0.0291	0.0372	0.00017	0.00012	952	743	3.015	2.663

Each band consists of P, Q, and R branches, the Q being, roughly, twice as strong as the P or R. Some of the branches have been followed up to rotational quantum numbers (K) above 80, but in the neighbourhood of the origin resolution has not been found possible below $K=6$. Nevertheless, the K values may be found without ambiguity, since both initial and final terms conform accurately to the formula $BK(K+1)$ up to $K=30$ at least. Owing to the large difference between the two B's, the R branch turns very quickly (in the neighbourhood of the third line), so that only a small correction (<1 cm.$^{-1}$) will be required to convert previous measurements of unresolved heads to true band origins.

The estimated values of r_0' and r_0'' used by Curtis and Darbyshire[1] in calculating potential energy curves for the ICl molecule are respectively 0.28 and 0.32 A. lower than those now found, but since it is $(r-r_0)$ which appears in the formula used, the necessary correction may be easily made by shifting the origin 0.3 A. along the r axis. The conclusions drawn from the curves depend on their relative position and are not affected by this change.

The rotation constants are given in the table, those for I_2 and Cl_2 being included for comparison. B_0'' is a direct determination, B_0' a least squares extrapolation using the formula $B_v'=B_0'-\alpha'v'$, in which v' runs from 8 to 12.

Detailed results based on more extensive measurements will be published later.

Raman Spectrum of Solid Nitrogen Peroxide

IN the course of work on the Raman spectra of solids at low temperatures, we have succeeded in photographing the spectrum of the light scattered by solidified nitrogen peroxide (N_2O_4), at a temperature of about $-80°$ C.

The spectrum is very simple, and consists of one line having a shift of 275 cm.$^{-1}$, and is sufficiently strong to appear as an anti-Stokes as well as a Stokes line, thus confirming the allocation to the particular exciting line (Hg 4358). The material absorbs too strongly in that region for shifted lines excited by Hg 4047 to appear.

X-ray intensity measurements show that at liquid air temperatures the molecule exists as NO_2 and is in a linear form.[1] If this is true at $-80°$ C. also, the Raman spectrum would probably consist of one very strong line, corresponding to the inactive fundamental frequency associated with the vibration of the oxygen atoms symmetrically about the stationary nitrogen atom, together with a very faint line corresponding to the linear active vibration. Such an explanation of the line observed is rendered less probable by the small magnitude of the shift, which might reasonably be more of the order of that due to the corresponding vibration in nitrous oxide (N_2O) (1282 cm.$^{-1}$ in the liquid[2]). Longer exposures are being made in an endeavour to bring up very faint lines.

Crystal Structure of Methane

IN view of the discovery by Clusius of a transformation point of solid methane at 20.4° K., it was interesting to investigate if there is a change of crystal structure or not. Heuse made a dilatometric examination of the transformation and found the very small volume contraction of 2 per mille, suggesting that the crystal structure is not altered. We have established this as a fact by making two X-ray exposures with solid methane at 21.1° K. and 18.5° K. respectively. The films were concordant within the limits of accuracy; they can be explained by assuming this structure to be a cubic close packed one, the side of the elementary cube being 5.88 A. The calculated density 0.52 is in perfect agreement with the value measured by Heuse.

McLennan and Plummer, too, in their X-ray analysis of methane, found a cubic close packed structure, with 6.35 A. as the side of the elementary cube, however, and calculated density 0.41. Moreover, the relative intensities of the lines we observed differ considerably from those given by these authors.

A more detailed account of this work will be published in the *Proceedings* of the Royal Academy of Amsterdam.

Forestry Research

I AM very glad to see in NATURE of April 4 the communications from Dr. M. C. Rayner and the Editor on this subject, and I am in cordial agreement with their remarks.

The extensive planting schemes initiated by the Forestry Commission afford a splendid opportunity for fundamental co-operative research on the building up of new forest soils. We know little enough about the soils of our native woodlands, and practically nothing about the conditions induced by planting exotic conifers on heath or grassland in our climate. It is certain that the knowledge acquired by properly planned research will save great sums of money in the future by preventing the waste of large-scale

mistakes It must be realised that except for two or three species the commercial planting of exotic conifers in Great Britain is still in the experimental stage It is essential to conduct such experiments with proper scientific control Forest botany and forest pedology have been seriously and wastefully neglected in the past by those responsible for planting schemes in this country

I should like to direct attention to a particular opportunity now available I understand that the future of the Cambridge Forestry School is at the moment under consideration That school, with proper support, would be able to initiate and carry through precisely the type of work required on the new plantations of the Forestry Commission in Breckland, and there is no other institution so conveniently situated for the purpose The Cambridge School can never hope to compete with the Oxford School, associated as it is with the Imperial Forestry Institute, in general Imperial forestry work But Cambridge is in almost an ideal position for undertaking fundamental intensive research on the Breckland forestry problems, and by doing so it will render a service of the first importance alike to science and to practical forestry It behoves all the authorities concerned to give every possible support to the well judged scheme of research which has been put forward by Dr A S Watt the University lecturer in forest botany at Cambridge

Segregation of Floral Characters in the Wild Oxlip

In quite a number of wild oxlip plants, presumably hybrids between the primrose (*Primula vulgaris*) and the cowslip (*Primula veris*), growing in situations where both the latter species abound, I find that the earliest formed flowers are borne on long peduncles of the primrose type, and are succeeded later, on the same plant, by flowers arranged on the umbelliferous type as in the cowslip Now, the question arises whether this dimorphic arrangement also occurs in *Primula elatior* (Jacq), the oxlip of East Anglia, which is regarded by some botanists as a distinct mutational variety or species If this segregation of floral characters is not found in *Primula elatior*, then this fact would favour the supposition that this species is a real mutational form and not a hybrid

The experience of field botanists working in East Anglia at this season of the year would be helpful in deciding this point So far, after the examination of some hundreds of plants, I have failed to find this dimorphic floral arrangement in any true primrose or cowslip plant The question is also important because it bears on the nature of segregation and the essential similarity of this process as it occurs in gametic and somatic cells

The Stimulation of Spermatozoa by Drugs

I have for some years been investigating the action of drugs on mammalian spermatozoa, under the auspices of the Birth Control Investigation Committee Finding that certain drugs seemed to stimulate sperms to higher activity, I have recently made a special study of this problem I have used guinea pig sperms taken from the epididymis and suspended in a glucose saline fluid buffered at about *p*H 8 Sperms are so active when first suspended in this fluid that the effect of stimulating drugs is not obvious In these experiments the sperm suspensions were allowed to remain for 5–8 hours at the temperature of the body before the addition of the drug After 5–8 hours, the activity of the sperms was markedly reduced The drugs were tested at concentrations in the series 1, $\frac{1}{4}$, $\frac{1}{16}$, $\frac{1}{64}$ per cent, etc

Strychnine hydrochloride was found to have a marked stimulating effect at $\frac{1}{16}$, $\frac{1}{64}$, and $\frac{1}{256}$ per cent, especially at $\frac{1}{64}$ per cent For practical purposes such a poisonous substance as strychnine is to be avoided, even in minute quantities Brucine hydrochloride was therefore tried, since its pharmacological properties are similar, while it is only about one eighth as poisonous It was found to stimulate sperms markedly at $\frac{1}{4}$, $\frac{1}{16}$, and $\frac{1}{64}$ per cent, especially at $\frac{1}{16}$ per cent At this concentration brucine hydrochloride has approximately the same stimulating effect on sperms as $\frac{1}{64}$ per cent strychnine hydrochloride, yet it is only about half as poisonous Brucine therefore seems preferable for practical use Chloral hydrate was also found to stimulate sperms at $\frac{1}{16}$ per cent, but far less than brucine and strychnine

It is hoped that this discovery may find practical application in medicine and agriculture, whenever sterility is due to inactivity of sperms Perhaps its most obvious application is in cases where sperms have been sent long distances for artificial insemination, and are found to be less than normally active on arrival at their destination Further experiments along these lines are about to be undertaken

Geodesy in India

On page 170 of Nature of Jan 31, 1931, appears an article entitled "Geodesy in India", by G T McC, being in the nature of a review of Geodetic Report, vol 5, of the Survey of India May I correct a small misapprehension into which the reviewer has fallen ?

In the sixth paragraph, reference is made to a decision " to re map at least a portion of the Dependency " This is not the intention The areas with which the Survey of India is concerned have been divided into a limited number of overlapping zones of 8° of latitude, to meet the military requirements In certain areas the latitude and longitude of fixed points have been converted into the corresponding 'grid' co ordinates and in some cases the grid lines have been or will be surprinted on the maps But there is no general question of re mapping at all

The width of 8° of latitude results in a variation in scale of about 1/400 or 1/800 from the average scale, and for the object in view this has been accepted as negligible However, in this orthomorphic projection it is a simple matter to apply a scale further varying with the latitude, and were this done, a much wider zone than 8° zone would give rise to little trouble or embarrassment The gain in increasing the zone width is of course reduction both in number of changes from one grid to the next and the consequential need for duplication in areas of overlap

Cytological Theory in Relation to Heredity *

By Dr C D DARLINGTON

THE chromosome theory of heredity, by relating chromosome behaviour with the phenomena of inheritance, has obviously made it possible to apply the cytological method to the study of inheritance With this profitable field before them, geneticists and cytologists have not hesitated to draw conclusions in the one field from observations made in the other, but in order to do so they have had to apply certain rules of interpretation Their method has naturally been to assume, so far as possible, a direct relationship between cytological and genetical observations The geneticist has therefore not only assumed that the material of every part of the chromosome has a specific genetic effect, which is a widely verified assumption , but also that the capacity of the chromosome for variation is equally specific, so that it is possible to refer to hereditary differences and to particles of chromosome alike as 'genes' This second assumption is also widely verified , but it is subject to serious exceptions in that two different kinds of change have been shown to befall the same particle, namely, internal change and external change such as loss or re-arrangement This constitutes no primary objection to the theory of the gene but rather indicates a necessary enlargement of its scope

Cytologists, on the other hand, in translating their observations into genetical terms, have sought to apply the chromosome theory to the interpretation of meiosis With the help of the simple rule that the pairing of chromosomes is a criterion of their relationship, they have set to work to examine meiosis in hybrids and in ring-forming plants (such as various species of *Œnothera*) The results of these studies have been confusing because investigators have not first examined the principles they were applying to see if they were indeed principles or merely empirical rules of special derivation and therefore of limited application We now have evidence by which to test them

Meiosis consists in the occurrence of two successive divisions of a nucleus in the course of which the chromosomes divide once instead of twice as they would in two ordinary mitoses Where the distribution of the chromosomes is regular, the four daughter nuclei therefore have half the number of chromosomes of the parent nucleus (Fig 1)

At the first division, the chromosomes come together in pairs, and a whole chromosome of each pair passes to one pole to divide at the second division of the nucleus To express this comparatively with regard to mitosis, we may say that while two half-chromosomes (or 'chromatids') are associated in pairs at a mitosis, four are associated at the first metaphase of meiosis A numerical reduction in the chromosomes must be attributed directly to the lack of any splitting of the chromosomes in the interval between the two divisions of the nucleus such as ordinarily occurs But this is readily related to the fact that each chromosome is already split into the two chromatids which have passed together to one pole This in turn is related to the pairing of the chromosomes

It has therefore seemed natural (since 1890) to regard the essential difference between meiosis and mitosis as consisting in the pairing of the chromosomes Since different pairs of chromosomes pass at random to the two poles (so that A_1-A_2 and B_1-B_2 may give daughter nuclei A_1B_1 and A_2B_2 or, equally, A_1B_2 and A_2B_1), and since the chromosomes are qualitatively differentiated, it follows that those which pair and pass to opposite poles must be similar if meiosis is to yield similar reduced nuclei (Boveri) Clearly, likeness is a condition of pairing But since the chromosomes that pair can be seen to be morphologically alike and therefore to be corresponding structures derived (so far as observation then showed) from opposite parents (Montgomery), it seemed enough to say that this pairing was due to the likeness of the chromosomes An 'incipient' association is often to be seen at mitosis in the somatic cells Perhaps, therefore, meiosis was the final step in the sexual process in which the maternal and paternal elements at last united

Such is, in a general way, the 'explanation' of meiosis that is current to day To be sure, we now know that the association cannot be attributed to an attraction between chromosomes derived from opposite gametes, since pairing has been found in meiosis in parthenogenetic organisms,[1 2] and very often between chromosomes derived from the same gamete in polyploid plants It may also be objected that this is merely to explain *ignotum per ignotius* But it is still taken to be a satisfactory basis for cytological, genetical, and evolutionary deduction Incompatible observations are freely ascribed to 'mechanical' or 'physiological' conditions

There are many recent observations of this kind There are tetraploid plants (such as *Primula sinensis*[3]), the nuclei of which contain four identical chromosomes of each of the twelve types that are represented twice in the diploid These chromosomes usually associate in fours at meiosis, as they would be expected to do if likeness were the sole condition of pairing But nearly always one, two, or three of these groups fail to be formed and their chromosomes appear merely paired This is not explicable on the affinity theory The chromosomes should be either *all* in fours or *all* in pairs

Other observations of the same type are (1) The occurrence of unpaired chromosomes in triploids, instead of all three identical chromosomes of each type being associated (*Zea*,[4] *Tulipa*,[5] *Lilium*[6]) (2) The occurrence of unpaired fragment chromosomes, although these have identical mates with which they can pair (*Secale*,[7] *Matthiola*,[8] *Tradescantia*[9])

* Substance of three lectures given at the Royal Institution on Mar. 10, 17, and 24

The only difference between these fragments and the other chromosomes which pair regularly appears to be their smaller size. If the triploids are examined, it is similarly found that the chromosomes which fail to associate regularly in threes are the small ones (*Hyacinthus*[10]). Therefore, not only *likeness* but also *size* bears some relation to the pairing of chromosomes.

If now we turn to consider the structures of the paired chromosomes at meiosis we find a variety of form that shows, at first sight, neither a rule in itself nor any clear relationship with ordinary mitosis. The two processes must be studied in their development in order to be seen in relationship.

The prophase of mitosis is characterised by a linear contraction of two threads, associated side by side, to become the two cylindrical rods which constitute the metaphase chromosome. At meiosis we find at the earliest stage a difference. The threads observed are single. They soon come together in pairs side by side and reproduce the conditions observed at the prophase of mitosis very closely indeed. But on account of their pairing they are present at this pachytene stage in half the number found at the prophase of a mitosis in the same organism. Evidently, therefore, the single threads at the earlier stage were chromosomes still undivided although in the earliest visible stage in mitosis they have already divided.

After an interval, splits appear in the pachytene thread separating it into two threads, each of which is now seen to be double. But instead of these splits passing right along the paired chromosomes and separating them entirely, it is found, when they meet, that the double threads that separate in one part are not the same pair of threads that separate in another. The separated pairs of threads therefore change partners, and the points at which they change partners (there are often several distributed along the paired chromosome) are called 'chiasmata'. This stage is diplotene (Fig. 1).

Between diplotene and metaphase there is further linear contraction, and the structure of the paired chromosomes may remain the same in regard to the relationships of the four threads of which they are composed; that is, the chiasmata may remain stationary. But they may undergo a change which consists in the opening out of the loop that includes the spindle attachment, at the expense of the adjoining loops, as though the spindle attachments of the chromosomes were repelling one another. In other words, the chiasmata appear to move along the chromosome towards the ends; finally, the chromatids are associated in pairs with changes of partners only at the ends. Such changes of partners are called 'terminal chiasmata', and the frequency of the end to end unions at metaphase corresponds with the frequency of the chiasmata seen earlier, when they were still interstitial, in small chromosomes (fragments) which only have one chiasma at most.[11] Further, in organisms with large chromosomes it is still possible to see the change of partner at the end; the association is double; it is between the ends of two pairs of chromatids, not merely between the ends of one pair of chromosomes.

These observations point to the chiasmata being the immediate cause of pairing between chromosomes. How can such a hypothesis be tested? It

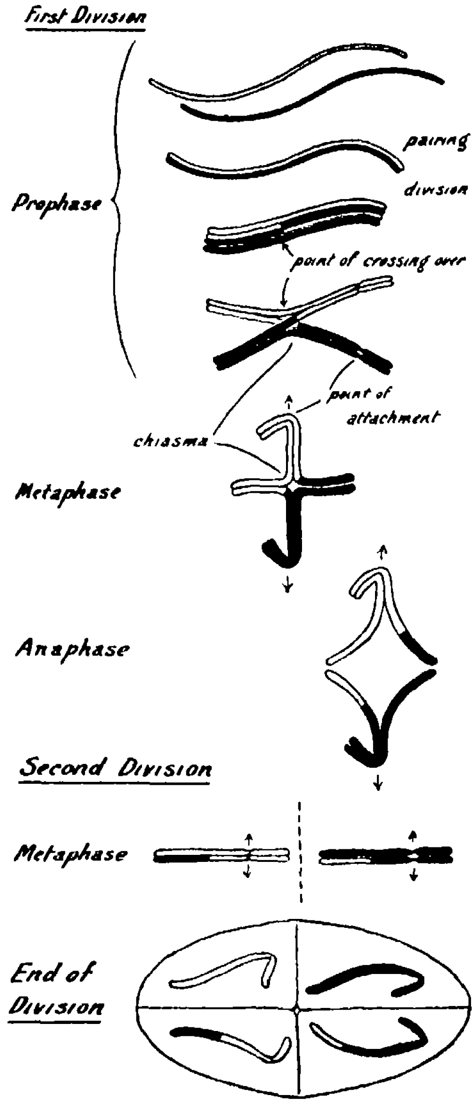

FIG. 1.—Diagram to show the development of one pair of chromosomes at meiosis and their relationship on the assumption that crossing over is the cause of chiasma formation. The four stages of prophase shown are (1) leptotene, (2) pachytene before division, (3) pachytene after division, (4) diplotene to diakinesis.

is found that given pairs of chromosomes have a constant range in the number of chiasmata formed. For example, in the *M* chromosome of *Vicia Faba*[12, 11] from 3 to 13 chiasmata are found at the metaphase, with a mean of 8·1. The *M* chromosome, which is much shorter has a range of 1 to 6, with a mean of 3·0. If we suppose that small chromosomes arising by fragmentation have a chiasma frequency proportionate to their length as compared with their larger neighbours, then we can predict from

observations of their size and of the observed frequency of chiasmata in the large chromosomes what their frequency of pairing will be, on this hypothesis Thus, in the variety "Yellow" of *Fritillaria imperialis* it was found that the chiasma-frequency was 2 58 in the large chromosomes The fragments were about one ninth of the length of the large chromosomes They should therefore have chiasmata in a frequency of 2 58/9 per pair, or 0 29 This means that they should pair in 0 29 cases (neglecting the frequency of one pair forming two chiasmata, which should be slight) They were observed to pair in 0 22 of cases [11] Here is an example of the type of observation which is susceptible of statistical analysis and supports this hypothesis

Now, if we admit chiasmata as the condition of chromosome pairing, a considerable simplification is possible in stating the relationship of mitosis and meiosis Throughout the prophase of mitosis, the threads are held together by an attraction in pairs The same rule applies to meiosis, for the evidences of failure of pairing of fragments, of odd chromosomes in triploids, and of the four chromosomes of a type in tetraploids all point to the chromosomes having no present attraction at metaphase They are merely held together by the chiasmata that is, by the attraction between the pairs of half chromosomes and the exchanges of partners amongst them, and this attraction exists equally at mitosis

This being so, we must look to the earliest stage of prophase to find the essential difference between the two types of nuclear division It evidently lies in the time at which the chromosomes split into their two halves At mitosis, it is probable that this has already happened before the chromosomes appear at prophase At meiosis, it does not happen until pachytene (possibly at the moment at which the diplotene loops appear) The prophase of meiosis therefore starts too soon, relative to the splitting of the chromosomes If we consider that there is a universal attraction of threads in pairs at the prophase of any nuclear division, as we see it at mitosis, it follows that this condition is fulfilled by the pairing of chromosome threads when they are still single, and their separation at diplotene when they have at last come to divide The decisive difference would therefore appear to be in the singleness of the early prophase threads in meiosis This singleness may be attributed to one or both of two causes (i) a delayed division of the chromosomes, (ii) a precocious onset of prophase The second of these seems the more likely explanation, on account of the short duration of the pre meiotic prophase in some animals Either assumption would account for the most characteristic of all secondary features of meiosis, namely, the exaggerated linear contraction of the chromosomes, paired or unpaired, if the time relationship of metaphase to the division of the chromosomes remains the same This hypothesis of precocity [13] may be tested by the observation of a correlation between irregularities in meiosis and (*a*) abnormality in the timing of meiosis, and (*b*) diminished contraction of the chromosomes at metaphase

The first of these tests is applicable to many organisms with occasional suppression of reduction, the aberrant nuclei enter on the prophase of meiosis either earlier or later than the normal nuclei [14 15 16 17] When they are too early, it may be supposed that a premature division of the chromosomes has precipitated the prophase, when too late, it may be supposed that the prophase has been delayed In either case the chromosomes would no longer be single at early prophase and the condition of their pairing would be lost

Such a cause of failure of pachytene pairing may be expected to be distinguishable by its effect on the contraction (the second kind of test) For when failure of metaphase pairing is not due to an upset in the timing of prophase but merely to failure of chiasma formation, we might expect normal meiotic contraction, this is the case in maize [18] Where the prophase has been delayed, we might expect an approach to mitotic conditions this is the case in *Matthiola* [19 20] Other critical evidence in favour of the hypothesis has already been quoted in these columns [21]

By trying to define in this way the relationship of meiosis to mitosis, we find out what is essential and therefore universal in meiosis, and what is unessential and secondary Only when the direct interpretation of events in the nucleus is clear (as it now seems to be) can we attempt their genetical interpretation on a satisfactory basis

Two examples of the genetical interpretation of chromosome behaviour at meiosis are of immediate importance It has been shown in every organism that has been adequately tested that crossing over can occur between corresponding parts of the paired chromosomes at meiosis, actually between the chromatids, so that crossing over in the region between *C* and *D* in a pair of chromosomes *ABCDE* and *abcde* will give four kinds of chromatid *ABCDE*, *ABCde*, *abcDE*, and *abcde* (Fig 1) We may suppose that this crossing over has no relation with anything observable cytologically that it takes place when the chromosomes are intimately associated at pachytene and has no connexion with later behaviour This view can only be taken when other possibilities are eliminated We may also assume that crossing over has some relationship with chiasmata, either as a cause ('chiasmatypy') [22 23] or as a consequence, through breakage and reunion of new threads [10 9] The last possibility has been eliminated by the statistical demonstration that terminal unions correspond in frequency with interstitial chiasmata,[11] and that the number of terminal chiasmata increases *pari passu* with the reduction of interstitial chiasmata [3 4 20] The first possibility, that the chromosomes fall apart as they come together, and that the exchanges of partners at chiasmata are therefore due to exchanges in linear continuity or crossing over between the chromatids, has been demonstrated in two ways

In tetraploid *Hyacinthus* and *Primula* associations occur with such a spatial relationship that

they can only be interpreted as the result of crossing-over [3, 25] In ring forming *Œnothera*,[28] chiasmata occur interstitially between a pair of chromosomes associated terminally with two others to give a 'figure of-eight' Such an arrangement also can arise only on the assumption of crossing over These demonstrations confirm Belling's interpretation of the *Hyacinthus* trivalents, which was not in itself indisputable [5] Whether the observations are of universal application (the simplest assumption) or not, can only be shown by cytological tests of organisms which have been studied genetically

A second problem is that of ring formation Since, on the present hypothesis, the pairing of chromosomes at metaphase is conditioned by the formation of chiasmata at prophase between *parts* of chromosomes of identical structure, it follows that ring formation (where one chromosome pairs in different parts with parts of two others) must always be due to different arrangement of parts, that is, different structure, in the chromosomes contributed by opposite parents [26, 27, 9] Thus the relationship of the chromosomes of two organisms can always be specified from the observation of the pairing behaviour of the chromosomes at meiosis in the hybrid It is therefore possible to study differences of such a magnitude as will sterilise a hybrid and are therefore not susceptible of genetical analysis This method is now being widely applied

Landscape at the Royal Academy

IN "Cape St Vincent" (669) we have an example of the work of the late W L Wyllie in which the revered veteran showed undiminished mastery of his craft The rush of the Atlantic rollers as they mount and comb on nearing the headland will recall to many, besides the present writer, a notable incident on the voyage from England to the East

In 'Moonlight Scilly Isles' (90), Mr Julius Olsson renders with his usual skill one of the most beautiful aspects of the coastal scenery of Great Britain, and the spark of the beacon on the head land both focuses the attention of the eye and adds to the emotional appeal of the picture In "Sunlight" (130), Sir Hughes Stanton depicts a promontorial town of the Mediterranean coast silhouetted against sea and sky, a picturesque relation of architecture and Nature for which we must seek foreign shores The austerities of Spanish landscape have attracted Mr Sydney Lee (' The Ox Cart", 79), Mr Guy Kortright ("Spanish Cactus", 243), and Mr Oliver Hall ("A Town of Southern Spain", 414) In the case of several pictures which embody either the golden glow and dark shadows of evening or lurid light and sombre clouds of storm, the artists have enhanced both the height and depth of tone and colour by a frame of black and gold Notable examples of this judicious device are "The Storm" (80) by Mr Philip H Padwick, "Evening in the Mountains" (268) by Mr William Clarkson, and "Mountains near Beddgelert" (281) by Mr Oliver Hall

In the fine study of "Amiens" (258) by Mr Terrick Williams, the shadowed cathedral owes its immensity to the foreground of small houses, caught by sunlight, on the quay It is an intriguing fact that impressiveness of size should bear so little relation to that which the astronomer calls the 'apparent magnitude' of an object A notable example of the dependence of the impression of size upon grouping is afforded by Windsor Castle, which when seen above the houses of the Borough assumes the appearance of a walled town crowning the hill

In "The Estuary" (301) by Mr Arnesby Brown, we have one of the characteristic landscapes of the British coast, with fine effects of atmosphere Towering clouds fill the larger part of the picture, the horizon of the land and sea lying very low in the field of view Underlying this practice or device of pictorial composition is the singular fact that although the eye is keen to note any lateral divergence from the vertical, it receives no warning sensation of a considerable departure from level outlook Hence great sky views are not so much determined by the circumstance of there being more sky, as by a natural grouping which lures the eye to an upward outlook

In "Northleach" (479), Mr William A Rixon gives us a faithful picture of Arcadian England, the harvest field and church tower, undulating landscape, and rounded masses of spreading trees, with soft white clouds floating overhead We may travel the world over but only in England will such a scene be found This is our particular heritage, which we should cherish and preserve

In Room X, devoted to Water-Colours and Tempera, Mr Cecil A Hunt, in "Glen Brittle, Isle of Skye" (933), has rendered with poetic feeling a

andscape of Britain which stands in greatest contrast to Arcadian England, the rugged range of the Cuillin Hills, pinnacles of dark, volcanic rock, rising above mists hanging in the hollows, where shadows are suffused with the atmospheric colour characteristic of the climate of the Western Highlands

In the Architectural Room, a perspective drawing of "Sydney Harbour Bridge, Australia" (1401), Sir John J Burnet and Partners, displays the latest triumph of steel construction, one of those great lattices which, when left unenclosed by masonry, stand out so splendidly against the sun set and the dawn

The Sculpture Gallery is of particular interest to the scientific community on account of portrait busts, including that of Mr G Buckston Browne (1530) by Mr Charles L Hartwell, Lord Dawson of Penn (1592) by Mr Henry Pegram, Dr Henry S Wellcome (1513) by Mr Edgardo Simone, Sir George Makins (1550) by Mr M Pownall Bromet, Miss Joan B Procter (1624) by Mr George Alexander, and Mr Allan G Wyon's fine rendering of the striking features of the late Sir Henry Wickham (1501), pioneer planter of para rubber in India

VAUGHAN CORNISH

Obituary

PROF A A T BRACHET, FOR MEM R S

ON Dec 27 the death took place, after a painful illness of several months' duration, of Dr Albert Brachet, of Brussels, professor of anatomy and director of the Laboratory of Embryology of the Faculty of Medicine in the University of Brussels He was a foreign member of the Royal Society and *correspondant* of the Paris Academy of Sciences, and was a distinguished leader in embryological science He was also well known in circles wider than those of professional embryologists as the author of the admirable 'Traité d'embryologie des Vertébrés"

Born at Liège on Jan 1, 1869, Brachet received his early training in embryology at the hand of Edouard van Beneden Later he became pupil and assistant to Auguste Swaen In 1904 he was appointed to the chair in Brussels, where he immediately instilled new life into anatomical study in that University

Brachet's permanent place in the history of vertebrate embryology will probably rest mainly upon his investigations into the morphological facts of development His early work with his master Swaen, upon the origin of the mesoderm and vascular system in Teleosts, was followed by a series of valuable investigations upon the early development of Batrachians, and these in turn by researches along corresponding lines upon Ganoid fishes and reptiles His morphological work bears the impress of a passing phase in the history of embryological science which followed as a natural consequence the flood of uncritical morphology poured out by the enthusiasts of the first few decades after Darwin The hasty work and ill-balanced speculation of those days naturally brought in its train a spirit of disillusionment as its errors became apparent—with the deplorable incidental result that one of the most fascinating branches of biological science became reduced for the time being to the level of mere fact-collecting

Brachet was not entirely unaffected by the sterilising spirit of the day He views the process of gastrulation merely as the attainment of the two-layered condition, the ectoderm and endoderm of the embryo merely as ectoblast and entoblast—without any recognition of that splendid and inspiring idea which appreciates their homology and consequent evolutionary significance Or again, as regards that other great idea of vertebrate morphology, the protostoma theory, Brachet, while showing intimate knowledge of the actual facts of observation, will have nothing to do with the evolutionary hypothesis which alone provides an explanation of the phenomena observed, and raises them from the level of mere facts to that of constituent parts of a consistent philosophy Nevertheless, without doubt, Brachet's name will live as one of the important builders of vertebrate embryology

Like so many of his contemporaries, Brachet became eventually drawn aside from the path of morphology into the territory of experimental embryology The spirit which animated the work of himself and of his department in later years cannot be better expressed than in his own words, as quoted in the birthday notice contributed on his behalf to NATURE of Jan 3, p 41

(1) " l'analyse de localisations germinales et du déterminisme de la morphogenèse chez les Vertébrés, spécialement les Amphibiens", (2) " l'étude de la physiologie de la mise en marche du développement et des cinèses de segmentation"

Along such lines, Brachet did much careful and interesting work It is clear that the reproductive cell of a complicated animal such as a vertebrate, possessing all its potentialities for reproducing the peculiarities of the parent, down even to comparatively trivial details, must have a physiology of immense complexity, far transcending human powers of investigation, and certainly the time is not yet for evaluating finally the achievements of experimental embryology It is one of the chief merits of Brachet's admirable experimental studies on the egg of the frog that he was able to demonstrate convincingly to what an extent the substance of the egg is already differentiated in its various regions before the act of fertilisation The further conclusion he reaches as to the active part played by the spermatozoon in readjusting and fixing the localisation of the various organ-forming portions of the egg rests on a less firm foundation

Brachet was no mere laboratory recluse Endowed with a lovable personality, a high idealism, and that power of oratory that caused him to be dubbed 'the Jaurès of Anatomy', he wielded great

personal influence among the students of his university In frequent request to take the chair at sociological meetings, he became the first president of the "Socialist Intellectuals", and at his funeral the Red Flag was prominent An ardent believer in the 'United States of Europe', he was inspired on one hand by his absolute belief in the socialistic ideal, and on the other by his horror and fear of the recurrence of war

In the administrative affairs of his university Brachet also exercised much influence He served his period in the high office of Rector, and his rectorial addresses were marked alike by their eloquence and their lofty and inspiring idealism It was during this period that he obtained the immense influence and inspired those feelings of affectionate regard that made his untimely death felt as a cruel blow throughout the university community

PROF W D ZELENSKY

THE news has just reached Great Britain of the death of Prof Wladimir Zelensky, professor of zoology and head of the Parasitological Department in the University of Leningrad, which occurred on April 27, 1930, at the age of fifty years

The late Prof Zelensky was one of the prominent zoologists of Russia His investigations were devoted chiefly to the morphology, biology, and systematics of leeches, his most important contribution being the "Investigations on the Morphology and Systematics of the Hirudinea 1 The organisation of the *Ichthyobdellidæ*" (1915) Lately Zelensky was engaged on a revision of this group of leeches on behalf of the Zoological Station of Naples, and worked on the collections of leeches belonging to various Continental museums He also prepared for publication the section on leeches for the "Handbuch der Zoologie", by Kukenthal In his earlier days Zelensky established the phagocytic function of the so called 'urnæ' in the Sipunculidæ During the present dearth of biologists of the old school in Russia, the death of Prof Zelensky will be a great loss to his country

WE regret to announce the following deaths

Prof R S Heath, formerly vice principal and professor of mathematics in the University of Birmingham, on April 15, aged seventy-two years

Prof W Valentiner, formerly professor of astronomy in the University of Heidelberg, on April 1, aged eighty six years

News and Views

ON May 3 shortly before 9 26 A M, a sharp local earth shake was felt, chiefly in the coal mining district to the north west of Manchester The area in which the shock was strongly felt is about 13 miles long and 9 or 10 miles wide, and includes about 100 square miles but at one or two places outside it was also slightly felt The shock was strong enough to cause slight damage such as overthrowing chimney pots, at Eccles Irlam o' th' Heights, Patricroft, etc Tremors were recorded at the Stonyhurst College observatory, beginning at 9 h 25 m 56 s and lasting 40 sec, but not at the Godlee observatory in Manchester nor at the Bidston observatory near Birkenhead The small disturbed area (probably less than 200 square miles) and the high intensity near its centre point to a very slight depth of focus, such, for example, as the depth of the coal seams worked in the district The longer axis of the disturbed area runs about north west and south east, in the direction of the Pendleton or Irwell Valley fault and the centre of the area lies close to the fault line It is probable that the earth shake was caused by a slip along this fault, and that the slip was precipitated, not by natural causes, as in the Bolton earthquake of Feb 10, 1889, but by the removal of coal in the neighbourhood of the fault It is of some interest to notice that the disturbed area of the recent earth shake almost coincides with that of one, not quite so strong, that occurred on Nov 25, 1905, and that the places where slight damage to chimneys occurred last Sunday lie close to the centre of the innermost isoseismal of 1905, and to the centres of similar but still slighter shocks on Feb 27, 1899, and April 7, 1900 (*Geol Mag*, vol 7, p 175, 1900 vol 8, p 361, 1901 and vol 3, pp 171 176, 1906)

ON May 4 the Huxley Memorial Lecture of the Imperial College of Science and Technology was delivered in the Royal College of Science by Sir Arthur Smith Woodward, who chose as his subject "Modern Progress in Vertebrate Palæontology" A more appropriate subject or a more befitting lecturer could scarcely have been selected for this particular memorial lecture Sir Arthur, first of all, briefly recapitulated the suggested scheme for the evolution of vertebrates originally proposed by Huxley, who drew up a definite sequence from Hypichthyes (an *Amphioxus* like ancestor) to the ancestral mammals, and then attempted to find their modern counterparts In emphasising the modern research work into the question of vertebrate palæontology, Sir Arthur showed how well our modern conceptions fit in with Huxley's ingenious scheme, and how much further modern workers have gone along the same theoretical lines, based on more practical material now available For example, whereas Huxley could find no modern homologue of the Hypotheria, Sir Arthur was successful in bridging this gap, in the light of modern knowledge So much has been discovered during recent years that Sir Arthur could not help but make some definite assertions with regard to vertebrate evolution, which only a short time ago he would not have been able to make For example, amphibians and reptiles are now so closely related by known fossils that their evolutionary sequence cannot be disputed

As was to be expected from such an authority as Sir Arthur Smith Woodward, the fishes were considered very fully The result was much information concerning American workers, perhaps to the detriment

of the workers of the Old World along this line of scientific work, who have been able to bring so much to light concerning man But perhaps it was a happy thought, for, whereas much information is available concerning man, especially since the discovery of *Sinanthropus*, the work on the lower vertebrates comes as a useful complement to it Here several points of interest and importance were emphasised For example, the work of Prof E A Stensio, of Stockholm, has given us a good idea of the Myrich thyes when they dominated the world, whereas their modern counterparts, the lampreys and hag fishes, are nowhere near enough for this Bone, too, which undoubtedly was preceded by dentine, in the first place as an exoskeleton, probably followed the dentine more closely than has previously been supposed Curiously enough, too, the links between groups are nearly always of the smaller types This, with other observations, leads Sir Arthur to the conception that most probably the same characteristics were arrived at along different channels, that groups began their evolution with definite inherent aims or potentialities which are difficult to describe at present, and that the impetus to evolutionary development was not so much a struggle for existence among the animals themselves as it was between the animals and their environmental conditions

Sir John Russell gave an analysis of the relation of man to the complicated modern machinery of civilisation, in his Essex Hall lecture entitled 'Man and the Machine", delivered on April 30 Sir John pointed out that, until recently, it was the empirical method that has prevailed in our methods of agriculture Empiricism, however, gave man but an uncertain control of Nature's forces In agriculture, scientific workers have been successful in discovering the chief factors controlling the growth of plants, and Lawes, the founder of the Experimental Station at Rothamsted, about 1839, first applied this knowledge so as to increase considerably the fertility of the soil and banish the spectre of food shortage from the world The application of artificial fertilisers and bacteria specially bred for the purpose, have made better crops possible Plant diseases have been brought under control, and disasters, such as the terrible potato blight brought into Ireland about a hundred years ago, can now be avoided The geneticist has, moreover, succeeded in determining many of the characters which decide the nature or properties of plants, their height of growth, time of ripening, etc The result is that, by selection, new types of wheat have been produced with power of early ripening intensified or capable of growth in areas of subnormal rain fall Consequently, arable land has been extended into the cold northern prairies and into the old desert lands, with a great expansion in the wheat potentialities of the world In 1898, Sir William Crookes declared that the methods and knowledge then current could not long suffice to feed the growing population of the world Science and practice have advanced, and, in place of famine, wheat is so abundant that the world's granaries hold far more than can be used Other foods are similarly available more abundantly than ever In the factories, labour saving appliances have become so effective that one man can do what it took the labour of several men to do only a few years ago

We are in possession, Sir John Russell said, of a new 'machine' that easily achieves things impossible to our fathers and does much of our work for us The 'machine' calls for specialists Thus is produced the increasing army of trained men The cultural effects of the 'machine' on the wider public cannot yet be clearly seen It tends to foster passive rather than active pursuits, it is thus inimical to the arts of self expression and self development The 'machine' is reducing the demand for human labour, and by no means equally As a result, a few are overloaded with work and an increasing number find themselves unwanted This displacement of labour is a new permanent factor in our life as a community, and it must increase in importance as the 'machine' further develops The contrast between conditions in the country and the towns is striking The man in the country is much less dependent on the 'machine' than the town dweller The very low rate of unemployment in rural England is in striking contrast with that of the industrial regions, showing the greater elasticity of country life as compared with that of the towns, and Sir John Russell is of opinion that the development of country life and country pursuits affords a promising way out of our present difficulties Our ultimate aim must be to use the machine for the common good

The lecture hall of the Institution of Electrical Engineers was crowded on April 30 to hear Prof W L Bragg give the twenty second Kelvin Lecture He chose as his subject "The Architecture of Solids", and gave a popular exposition of modern theory which was much appreciated by his audience He divided solid bodies into three great classes, metals, organic substances, and inorganic substances Iron, wood, and stone are representative of these classes Metals differ from the others by the presence of free electrons, the attraction between which and the positive ions gives the structure its stability The basis of the structure of pure metals and alloys is one of close 'packing', but the radii of the atoms in metals are much greater than those of the ions in crystals The structures of pure metals are very simple X rays have proved of the greatest value in obtaining an insight into the real constitution of alloys The structure of metals and alloys can be found, but it is very difficult to picture the structure of organic substances The constitution of inorganic substances is a problem in electrostatics The stable configuration is that in which the potential energy is a minimum This enables even the constitution of very complex compounds to be found When these structures are found, we can study the effects of extension and compression on solids and the effect produced by heating them Special hypotheses have to be made in several cases, as, for example, when explaining the expansion of metals by heat Theoretically, heat should be transmitted through salt with the velocity of sound, and rock salt should be stronger than the strongest

steel Prof Bragg gave a convincing explanation of why heat travels much more slowly than this in insulating materials He regards a sheet of mica as simply an electrical condenser It has great mechanical strength parallel to the sheet and very little perpendicular to it

THE twenty first annual May lecture of the Institute of Metals was delivered on May 6 by Mr William B Woodhouse, past president of the Institution of Electrical Engineers Mr Woodhouse reviewed the development of power production throughout the world and in particular the important question of the extent to which Great Britain, dependent as it is on coal for power production, can compete with water power in other countries in the production of cheap electricity for metallurgical and other industrial purposes Electrical methods of treating ores and of producing and refining metals are used to an extent which requires very large amounts of power and is rapidly growing Electric power is being produced in Great Britain by the consumption of coal at a price which compares favourably with water power in other countries The great development of water power in other countries and the large amount still unused calls for the most careful consideration of our relative position as a power-producing country The use of oil fuel, its effect on the production and demand for coal, and the prospects of producing oil fuel from British coal, were also discussed The progress of electric power supply by a single organisation over a wide area, initiated in England some thirty years ago by the electric power companies, the developments of which have, in the face of great difficulties, provided a general supply of electricity at a low price, led the way to nationally and internationally interconnected systems of supply in all parts of the world, and in Great Britain to the establishment of the 'grid' by the Central Electricity Board It is practicable to obtain large amounts of electricity from efficient power stations in Great Britain at a price as low as one fifth of a penny a unit or even less for secondary power or restricted supplies

IN September 1929 the Government appointed a committee to consider and report upon the desirability and feasibility of establishing one or more National Parks in Great Britain, and with commendable promptitude the Report of the National Park Committee has just been issued (Cmd 3851 London H M Stationery Office 2s net) It deals generously with the terms of reference, and covers a wide range of aspects of the preservation of scenery, of fauna, and of flora The objects to be achieved by a system of natural reserves and Nature sanctuaries in Great Britain are stated to be three fold the safeguarding of areas of exceptional natural interest against disorderly development and spoliation, the improvement of means of access for pedestrians to areas of natural beauty, and the promotion of measures for the protection of flora and fauna The Committee is strongly in favour of the preservation of such areas for the public, and makes suggestions for the extension of planning powers and for the formation of regional committees which would see the necessary arrangements carried through. It distinguishes between national reserves, of interest to the nation as a whole, and regional reserves, selected for their convenience of access from industrial centres, but thinks that at the present stage it would be premature to select specific areas The variety of opinion with which the Committee had to deal is well and interestingly illustrated in the summaries of evidence which form an appendix to the Report

THE annual meeting of the members of the Royal Institution, for the election of officers and to receive the report of the visitors for the year 1930, was held on May 1 Lord Eustace Percy was elected president, Sir Robert Robertson treasurer, and Major C E S Phillips secretary In August last, the Institution suffered the loss of its president (and devoted servant), the Duke of Northumberland, a vacancy filled afterwards by the election of Lord Eustace Percy The roll of the Institution at Dec 30, 1930 comprised 944 members Of 40 members deceased, special reference is made to eight, whose average tenure exceeded fifty years Lord Balfour had been a member for sixty years The managers are in the fortunate position of being able to report the completion of the alterations to the building, involving in parts a reconstruction The house is now fully open to members, and the library books, apparatus, and equipment have been replaced The Faraday celebrations in September will therefore be held under happy home auspices Additional cause for congratulation is found in the situation that the efforts of the managers to meet the expenses of the alterations have proved successful There will be no contingent burden of debt to carry forward Besides receiving generous donations from immediate friends, the Institution has derived most timely and substantial aid from the Pilgrim Trust

IT is not the British way to allow a regularly established and accredited organisation to fail, otherwise the Royal Institution would have ceased to function, during earlier generations, in any national sense and conception The adoption of the new plan of management and activities promulgated in 1810 brought, however, permanent ideals and adherents Notwithstanding, the managers in those times endured heavy financial trials, still, they held on In 1814, during the absence of Sir Humphry Davy, "the Institution did little for science, but though poor, it strove to be fashionable" (Bence Jones) It gave "a cold collation" to the Grand Duchess of Oldenburgh on May 23 of that year The funds were not flourishing, as premised, indeed, many bills were paid out of a special benefaction fund for discharging debts Somewhat earlier, the managers had refused lectures on physiology and comparative anatomy "because they could not convince themselves that scientific lectures can be given on these subjects without offence to a part of their audience" Varied as the story is, of which present day managers of the Royal Institution must have ample knowledge, the past fluctuations of

the establishment provide stimulating thought and instruction Faraday gave his first lecture within its walls in 1824

A NOTEWORTHY feature of the Safety Week arranged by the National Safety First Association, which is to be held in Leeds on May 11 16, is the chemical session arranged for Tuesday, May 12 This session, at which Dr E F Armstrong, chairman of the Association of British Chemical Manufacturers and of its Works Technical Committee, will preside, is open not only to members of the chemical and allied industries but also to representatives of all firms which are members of the National Safety First Association The Association of British Chemical Manufacturers has already been responsible for much valuable work in regard to safety in the chemical industry A series of *Safety Circulars*, giving information on accidents occurring from time to time in chemical industry, and indicating precautions which may be taken to avoid their repetition, as well as a quarterly summary of safety literature, are regular features of the Association's activities In addition, the Works Technical Committee has already issued Part 1 of "Model Safety Rules for Chemical Works", and a first section of Part 2, dealing with fire and explosive risks

AT the chemical session on May 12, Mr J Davidson Pratt, general manager of the Association, will present a paper on the cleaning and repair of vessels containing dangerous materials This is a subject of interest to almost every industry and neglect or ignorance of the precautions to be used in cleaning or repairing containers, particularly those used for organic solvents, has been responsible for numerous accidents, many of which have been fatal The incidence of such accidents is far from being confined to chemical industry, where the necessary precautions are indeed comparatively well known and observed, and one of the fundamental problems of industrial safety is indeed here encountered—that of securing the dissemination of the safety information in every quarter where it may be of use The Leeds meeting provides a valuable opportunity for the consideration of an important safety problem, and a good attendance should ensure that the principles to be observed in handling such containers are made known in quarters not otherwise easily reached

AT a meeting of the International Executive Council of the World Power Conference of 1929 the need for a comprehensive and authoritative survey of current literature on power, fuel, and related subjects was recognised and a sub committee appointed by the British National Committee considered the suggestion Its report was unanimously approved at the meeting held in Berlin in June 1930 It was suggested that a bulletin be prepared, with the following recommendations (1) Each country to abstract its own literature, the abstracts to be in English, French, or German, (2) the abstracts to be indexed in accordance with the Universal Decimal Classification, (3) the arrangement of the abstracts to follow that in use by the Institut international de Bibliographie, to be printed on one side of the paper only, and to be capable of being mounted on 5 in × 3 in cards This last recommendation is a good one, since it allows for either binding annually or a card index system The first number of this *Power and Fuel Bulletin*, published by the British National Committee, has recently appeared The abstracts are grouped under four main headings—(*A*) sources (fuel, water, wind), (*B*) generation (steam, electricity, water, mechanical power), (*C*) distribution and storage (steam, electricity, water, gas, oil, pneumatic), (*D*) utilisation The following organisations are co operating in the compilation of the bibliography Fuel Research Division, Department of Scientific and Industrial Research, British Chemical Plant Manufacturers' Association, British Electrical and Allied Manufacturers' Association, Institution of Petroleum Technologists, National Federation of Iron and Steel Manufacturers, and the National Gas Council of Great Britain and Ireland The *Bulletin* will be published monthly, and the subscription is ten shillings for twelve issues A copy of the first number and a subscription order form will be sent, post free, on application to the Honorary Secretary, British National Committee of the World Power Conference, 63 Lincoln's Inn Fields, London, W C 2 The National Committees in Czechoslovakia, Germany, Japan, and Poland have also begun publication, or will do so in the near future

AN instructive article appeared in the *Times* of May 1, concerning two new research stations, of much importance to the deep sea fishing industries of the British Empire, which have been founded in Newfoundland and Scotland The Newfoundland station, which is being set up jointly by the Newfoundland Government and the Empire Marketing Board at Bay Bulls (near St John's), starts operations this spring The Torry station, under the Department of Scientific and Industrial Research, and also financed largely by the Empire Marketing Board, has been in existence at Aberdeen for a little more than a year These two stations represent the latest endeavours to organise and conduct scientific investigations on two great problems with which the modern fishing industries are confronted Newfoundland, as a great exporter of fish, will be served by the scientific workers at Bay Bulls in the search for a fuller knowledge of the great natural fluctuations in yield of the fisheries for cod and other economically valuable fish, knowledge which will render possible the establishment of an effective intelligence service for recording the movements, quantities, and quality of the fish shoals upon which the fishermen depend At Torry, on the other hand, efforts are being directed towards the perfecting of methods designed to preserve the catch in the best possible condition as food and in a form which will appeal to the palate of the consumer Success at Bay Bulls will free the producer from the present trammels of uncertainty in yield, while good work at Torry will facilitate the successful exploitation of far distant fishing grounds, and ensure to the consumer a better and more acceptable food commodity

IT is pointed out, in a recent *Daily Science News Bulletin*, issued by Science Service, Washington, D C,

that the route of the proposed Nicaraguan canal lies almost directly across the epicentre of the earthquake that ruined Managua on Mar 31 That epicentre lies in lat 11 9° N long 86° W, close to the north western end of Lake Nicaragua Another shock of similar intensity from the same origin might cause great damage to canal locks and power houses, or to the canal itself by landslides It is worth noticing, however, that in all excavations, the intensity of an earthquake is much less than on the surface This fact has frequently been experienced in railway tunnels and in mines, and even at the bottom of pits 10 18 ft deep as was shown by measurements made in Japan about forty years ago by Milne, Sekiya, and Omori (*Trans Japan Seis Soc* vol 10, pp 25 26, 36, 1887, and vol 16, pp 19 45, 1892)

ADMIRAL D W TAYLOR U S N and Rear Admiral Sir Douglas Brownrigg Bart, have been elected honorary vice presidents of the Institution of Naval Architects

AT the meeting of the Royal Society on May 14 there will be a discussion on "Ultra penetrating Rays" The discussion will be opened by Prof H Geiger, of Tubingen, followed by Lord Rutherford and others

THE centenary of the birth of David Edward Hughes (May 16 1831) will be commemorated at the Institution of Electrical Engineers on May 14, when a short discourse on the life and work of Hughes will be delivered by Mr Sydney Evershed

THE sixteenth Guthrie Lecture of the Physical Society will be delivered by Sir Richard Glazebrook, who will take as his subject "Standards of Measurement, their History and Development" The lecture will be delivered at 5 15 P M on Friday, May 15, at the Science Museum South Kensington

THE Carnegie Gold Medal of the Iron and Steel Institute has been awarded to Mr E Valenta, of the Skoda Works Pilsen, for his work entitled Heat and Acid resisting Cast Iron with High Chromium and Carbon Content"

BY his will, the Hon Sir Charles Algernon Parsons, who died on Feb 12, aged seventy six years bequeathed £4000 to the North East Coast Institution of Engineers and Shipbuilders, £3000 to the Armstrong College, Newcastle, £3000 to the Royal Institution of Great Britain, and £2000 to the British Association

THE second Spiers' memorial lecture of the Faraday Society will be given by the president, Dr Robert L Mond, on June 17, at the Royal Institution The lecture will be entitled "Michael Faraday", and tickets for admission may be obtained from the Secretary of the Faraday Society, 13 South Square, Gray's Inn London, W C 1

THE Geological Society of London will hold a conversazione in the Society's apartments in Burlington House on June 3, from 8 30 to 11 P M During the evening, Dr W F Whittard will describe the geological work of the Cambridge expedition to Greenland in 1929

AT a dinner of the Society of Apothecaries on April 28 Sir Stanley Hewett, Surgeon Apothecary to the King, was presented with the diploma of the Society (*honoris causa*) This is the third time only that the honorary diploma has been presented, the other two having been awarded to the Prince of Wales and Sir John Lynn Thomas, consulting surgeon of King Edward VII Hospital and to the Welsh National Memorial Association

THE Council of the Institution of Civil Engineers has made the following awards in respect of papers read and discussed at the ordinary meetings during session 1930–31 A Telford Gold Medal to Mr W T Halcrow (London), Telford Premiums to Mr F R Freeman (London), Mr G C Minnitt (Bombay), jointly to Mr C S Berry, Mr H P Gaze, and Mr C E H Verity (London), and jointly to Prof A H Gibson (Manchester), Mr T H Aspey, (Wigan), and Mr F Tattersall (London), a Manby Premium to Mr A R Ellison (Nag Hammadi, Egypt), a Crampton Prize to Mr R T McCallum (Derby), the Council would have awarded a Telford Premium to Mr Percy Allan (Sydney, N S W) had he been still living

THE Dorothy Temple Cross Research Fellowships in tuberculosis for the academic year 1931-32, for persons "intending to devote themselves to the advancement by teaching or research of curative or preventive treatment of tuberculosis in all or any of its forms", will be awarded shortly by the Medical Research Council Candidates must be British subjects and possess suitable medical, veterinary, or scientific qualifications The fellowships will preferably be awarded to those who wish to conduct inquiries outside Great Britain They are generally awarded for one year, and are of the value of not less than £300 per annum, with travelling expenses in addition It may also be possible to award a Senior Fellowship of considerably greater value to a specially well qualified candidate wishing to undertake an intensive study of some particular problem of tuberculosis at a chosen centre of work outside Great Britain Particulars and forms of application, to be returned before June 6, are obtainable from the Secretary, Medical Research Council, 38 Old Queen Street, Westminster, S W 1

APPLICATIONS are invited for the following appointments, on or before the dates mentioned —A director of the Research Institute of the Cancer Hospital, Fulham Road—The Secretary, Cancer Hospital, Fulham Road, S W 3 (May 11) An assistant master for mathematics and electrical engineering in the Junior Technical School for Boys of the Paddington Technical Institute, and for evening classes—The Education Officer (T 1), County Hall, S E 1 (May 16) A technical assistant under the Department of Scientific and Industrial Research, for abstracting work in connexion with fuel research—The Secretary, Department of Scientific and Industrial Research, 16 Old Queen

Street, S W 1 (May 18) A technical assistant in the department of economics of the Edinburgh and East of Scotland College of Agriculture—The Secretary, Edinburgh and East of Scotland College of Agriculture, 13 George Square, Edinburgh (May 18) An assistant tutor for adult education in rural districts, principally, in North Lancashire under the Lancashire Education Committee—The Director of Education, County Offices, Preston (May 20) An assistant lecturer in mathematics at Westfield College—The Principal, Westfield College, N W 3 (May 27) A principal of Brierley Hill Technical Institute—The Director of Education, County Education Offices, Stafford (May 27) A student probationer (zoologist or physiologist) at the M B A Laboratory, Plymouth—The Director, Marine Biological Laboratory, Plymouth (May 29) An assistant lecturer in the department of mathematics of the University College of Swansea—The Registrar, University College, Singleton Park, Swansea (May 30) A professor of pathology in the University of Hong Kong—The Chief Medical Officer Ministry of Health, Whitehall, S W 1 (June 24) A part time lecturer in engineering production and works management at Battersea Polytechnic The Principal, Battersea Polytechnic, S W 11 A biology master at Haileybury College—The Master, Haileybury College, Hertford

Our Astronomical Column

The Siberian Meteor of June 30, 1908—The *Scientific American* for April contains a note by J G Crowther on the above meteor, which is undoubtedly the most remarkable one on record It will be remembered that many square miles of forest were levelled, thousands of reindeer killed, and that a blast of hot air was felt by people at a considerable distance from the fall Mr Crowther now reproduces barographs taken on that day at five stations in England, they all show a series of well marked oscillations, at times that get later as they are farther from the place of the fall The deduced velocity is about that of sound, and the time of travel from Siberia to England is 5 hr 10 min, which is about right for a sound journey of 3550 miles Hence there is little doubt that the oscillations indicate air waves produced by the fall

There is, however, a further phenomenon, that evening there was a remarkable, red sunset glow which lasted all night At midnight it looked like the glare of a distant conflagration A photograph of the Greenwich Naval College was taken from the Royal Observatory at midnight by the light of the glow It was discussed at the meeting of the British Astronomical Association on July 1 (see *Jour Brit Astr Assoc*, **18**, No 9, p 354) Mr H P Hollis said "About half past nine as seen from Greenwich, it did not differ much from a fine sunset, except that the luminosity was more to the north than sunset effects usually are, but the appearance lasted, and at one o'clock had shifted a little to the east, being if anything rather more brilliant than it had been earlier But the most remarkable thing was the light over the whole of the northern sky, which was then as bright as the southern sky is when there is full Moon "

The writer of this note remembers that at the time he compared the phenomenon with those that followed the eruption of Krakatoa in 1883, and suggested that there might have been an eruption in some little known region But it now appears that it was probably due to dust raised by the meteor, and carried westward by the same rapid current in the upper air that carried the Krakatoa dust so quickly round the world The speed would be 185 miles per hour Mr Crowther records that at 7 P M on June 30, Mr de Veer, of Haarlem saw "an undulating mass to the north west, it was not cloud for the blue sky itself seemed to undulate"

The meteor may have belonged to the Pons Winnecke swarm, but it could not (as is erroneously suggested in the article) have been the comet itself, as that passed perihelion on Oct 9, 1909, so that it was a long way from the earth in June 1908

Temperatures of the Sun, Moon, and Mars—Prof H N Russell gives in the *Scientific American* for April an account of recent researches at Mt Wilson by Messrs Pettit and Nicholson using a delicate thermopile on the 100 inch reflector They find for the moon's surface under a vertical sun the temperature 101° C, just above boiling water, at altitudes 60°, 30°, and 10° the temperatures are 88°, 40°, and −30° respectively They studied the effect of an eclipse of the moon, finding that a region that was at 60° C before the eclipse began, fell to −100° when the region entered the umbra, the return of heat after the eclipse was also rapid, suggesting that the moon's surface is composed of loose volcanic ash and that the heat only penetrates a few inches below the surface The temperature at night is concluded to fall below −150° C There is thus a range of 250° C between day and night in the equatorial regions of the moon, this would tend to disintegrate rocks by alternate expansion and contraction, as R A Proctor pointed out fifty years ago New observations on Mars indicate that with an overhead sun in perihelion the temperature is 18° C The temperature at the pole at the end of summer is about the same Observations of sunspots gave for their temperature 4750° K, or about 1200° cooler than the surrounding photosphere This refers to the middle of the disc, where vision penetrates to a lower layer in the sun than with oblique rays

Perturbations of Wolf's First Periodic Comet—*Circular* No 10 of Warsaw Observatory contains a summary of Prof M Kamienski's exhaustive researches on the motion of this comet from 1884 to 1919 The comet was observed at every return in this interval, except that of 1905 After the perturbations of all the planets except Mercury and Neptune have been carefully computed and applied, there are several fairly large residuals, amounting in seven cases to 14″ or more It is shown that these can be greatly reduced by the assumption that the mean daily motion of the comet is diminishing by the amount 0 00000042″ per day, this is in addition to the changes due to planetary perturbations There is now one residual of 6″, one of 5″, the remainder are less than 4″ The mean residual is reduced from 6 5″ to 1 8″ The author points out the similarity to the case of Encke's comet, found by Prof O A Backlund to have an increasing mean daily motion De Sitter's value of the mass of the system of Jupiter was used, it is 1/1047 40 Incidentally, the result supports de Sitter's conclusion that it is better not to use results based on comets in adopting the mass of Jupiter, since these are subject to unexplained anomalies

Research Items

Art of the Bush Negroes of Dutch Guiana—For some years, Dr Morton H Kahn has conducted expeditions to Dutch Guiana on behalf of the American Museum of Natural History, with the object of investigating the culture of the descendants of the West African Negro slaves who revolted from the Dutch in the seventeenth century, and have remained practically untouched by white or Indian influence ever since He has now contributed to the *Journal* of the Museum an advance account of their art in anticipation of a book on these people which he is about to publish Their art is a well developed highly conventionalised form with considerable social significance Common objects of every day life are developed by carving into highly elaborated forms Combs, paddles, stools, and other objects show great beauty of form and design with a sense of line and balance The carving is done by men, and the objects have a ceremonial significance, for these wooden pieces are tokens of love Though the people are largely promiscuous, there is a certain amount of wooing necessary, which is done by means of the presentation of a carved object A woman is, therefore, proud of her collection of carved objects and does not part with them readily, for each piece is the token of the affection of a male As a skilful carver is held in considerable repute, and those who are not skilful must obtain their services by trading game or fish, wood carving is practised assiduously from boyhood The carved objects are made of hard jungle wood, some of lignum vitæ, those of light wood not being popular The carving is done with a jack knife and a pair of compasses and finished with matted grass and river sand The objects are not used for trade purposes Colour other than that natural to the wood is not usually shown, though occasionally inlay of other woods is employed The objects are sometimes so highly carved as to be useless The symbolism of the designs is individual Prominent motives are the snake, the vulva, and the human scapula

Ecological Methods and the Tsetse Problem—In *Ecology*, vol 11 (1930), pp 713 733, Dr J F V Phillips discusses the application of ecological methods to a better understanding of the behaviour of the tsetse fly (*Glossina* spp) in Tanganyika Territory At least 60 per cent of the country is either lightly or densely infested by various species of *Glossina*, the most important being *G morsitans* and *G swynnertoni* In 1925 funds became available, through the Tsetse Subcommittee of the Committee of Civil Research, for the establishment of a special department for the scientific study of the vectors of trypanosomiasis and its organisation upon lines of modern ecology The detailed application of the latter method, it may be added, is under the direction of Dr Phillips The conception of the plan of campaign is based upon the fact that tsetse flies are associated in varying degrees not only with the specific animals upon the blood of which they feed, but also with vegetation communities The tsetse fly investigator requires, therefore, to be versed both in the purely entomological aspects of the problem, and also to have a knowledge of the relationships of the biotic communities whereof the insect is a constituent It would appear that a productive method of helping to solve the menace of these insects lies in an understanding of its ecology The principal lines of investigation include the detailed study of the insects in relation to the physical and biological characters of their environment, their interrelations with the vertebrate fauna, their biological control and the experimental alteration of the biotic and physical characters of selected areas These and other aspects of this great problem are discussed in this paper which outlines a comprehensive and far reaching plan of campaign

Fauna of the Dutch East Indies—The scientific results of the expedition of the Prince and Princess Leopold of Belgium accompanied by Prof Van Straelen in 1929 (Résultats scientifiques du Voyage aux Indes Orientales Néerlandaises de LL AA RR le Prince et la Princesse Léopold de Belgique, publiés par V van Straelen, Directeur du Musée Royal d'Histoire Naturelle *Mémoires* du Musée Royal d'Histoire Naturelle de Belgique) are being published handsomely in quarto form, eight parts of which have been issued in 1930 These cover a wide field, and each is written by an expert Vol 2 contains "Suesswasserschwaemme", fas 2, by Walther Arndt, "Cœlentères hydropolypes", fas 3, by E Leloup, "Schyphomedusen", fas 4, by G Stiasny, and "Oligochæten", fas 5, by W Michaelsen vol 3 includes fas 1, "Isopoda (excl Oniscoidea and Epicaridea)" by A F Nierstrasz, and "Isopoda Epicaridea" by H F Nierstrasz and G A Brender a Brandis, fas 2, "Parasitic Copepoda" by W H Leigh Sharpe, and fas 3, "Cirripedes" by C A Nilsson Cantelli—vol 5, fas 1, containing "Batraciens" by S F de Witte The most comprehensive are the parts on the oligochætes and the Crustacea, fourteen species of cirripedes being recorded from various parts of the Malay Archipelago, including a new genus and two new species, two new species of parasitic copepods, and some interesting new isopods The oligochætes collected belong mostly to the large genus *Pheretima*, and these are very carefully worked out Most of the papers are illustrated by text figures, but there are line drawing plates in Leigh Sharpe's "Parasitic Copepoda" and photographic plates in Leloup's "Hydroids", all of which are good

Growth of Lobsters—An appendix to the *Interim Report* (Report on Crabs, 1930) of the Interdepartmental Committee on Crabs and Lobsters (London H M Stationery Office), by Mr Richard Elmhirst, brings out some interesting facts with regard to the growth of lobsters The growth curves from all available data show that a three year old lobster is about 110 mm long These data are from lobsters reared in captivity and also from those marked and recaptured After about seven years the growth is slow At about ten years old the males and females are of equal size, but nearly all very large lobsters are males At first the females grow faster than the males, but when maturity sets in the growth is slower Weighing experiments which have been undertaken at the Millport Laboratory, especially with reference to the increase of weight at moult, show that this increase may be as much as 30 per cent, but exceptional cases are cited and one lobster was actually lighter after the moult The cast shell is eaten by the lobster, even if this is withheld for some time There is no relation between the weight of exuviæ consumed and the increase of weight during the shell eating period, the lime taken in during hardening probably replacing water in the skin The data available show that the inter moult increase is about 10 per cent in males and 8 per cent in females Tables are given showing details both of lengths and weights

***Parapseudecheneis*, a New Genus**—Dr Sunda Lal Hora and Dr Paul Chabanaud have studied the siluroid fish *Pseudecheneis paviei* in much detail, and find that it is undoubtedly not congeneric with *Pseudecheneis sulcatus*, the only other species ascribed

to the genus In their paper "The Siluroid Fish *Pseudecheneis* and an Allied New Genus" (*Records* of the Indian Museum, 32, 3, Oct 1930) they describe the characters of both genera *Pseudecheneis* and *Parapseudecheneis* both have an adhesive apparatus composed of a series of transverse lamellæ resembling in superficial appearance and form the adhesive disc of *Echeneis* or *Remora*, but they are quite different in general form, especially in the head region It is suggested that both genera are derived from those members of the genus *Glyptosternum* which live in calm and placid waters of the highlands of Central Asia The fact that the pectoral fins are placed somewhat higher than the ventral surface of the body shows that they have taken to life in rapid waters comparatively recently, and that their ancestors were probably well adapted for life in deep and calm waters *Pseudecheneis* and *Parapseudecheneis* appear to have been evolved from two different stocks, but, under the influence of the current, have developed a similar type of adhesive apparatus

Larch Poles for Transmission Lines—Experiments have been carried out at the Forest Products Research Laboratory at Princes Risborough in the treatment of home grown larch poles to render them suitable for use in telegraph, telephone, and power transmission lines The objections to larch (which for many purposes has long been held in high repute in Great Britain) for transmission lines are apparently based on the behaviour of creosoted poles used during the War It was recorded of those poles that the creosote did not penetrate the pole to any depth when subjected to the methods of treatment then in use, consequently after erection the poles were liable to crack or split severely Experiments carried out with consignments of poles from the well known larch woods in Tintern Forest have shown that with suitable treatment these difficulties can be overcome By peeling and making a number of incisions in the poles with a broad knife, a satisfactory penetration of the preservative is obtainable Although the incisions have a slight weakening effect on their strength, home grown larch poles so treated are said to be 25-30 per cent stronger than imported poles of Scots pine of the same dimensions Provided, therefore, that the larch poles are grown as clean as the imported pine, they should easily be able to hold their own in competition *Bulletin* No 8 of the Forest Products Research Laboratory (Jan 1931), recently issued by the Department of Scientific and Industrial Research, gives full technical details of the experiments carried out

The Old English Mile—In a paper recently published in the *Geographical Journal*, Sir Charles Close showed that the mile in use in the fourteenth century in England was not less than ten furlongs Lieut Col J B P Karslake returns to this matter in the *Geographical Journal* for April, and shows that the old English mile was actually eleven furlongs This can be proved to be the mile of 1500 paces It was identical with the *leuga*, the common unit of maximum linear measurement in early Saxon times It was introduced into England in the first century B C, and it is the measurement that was used in the Domesday survey Apparently it was replaced by the mile of eight furlongs by the use in Saxon times of the Roman mile of 1000 *passus*, divided into eight *stadia* So early as the ninth century, the *stadium* became the equivalent of the furlong This mile of eight furlongs was adopted by the Post Office on its establishment in the reign of James I for the determination of rates of horse hire for postal purposes Thus milestones eight furlongs apart were set up, and this mile became the accepted standard of measurement in Great Britain

The Labrador Current—In a report on the coastal waters of Labrador based on explorations in 1926 (*Proceedings* of the American Academy of Arts and Sciences, vol 66, No 1), Mr C Iselin directs attention to certain features of the Labrador current revealed by sections across its waters Two sections showed that the colder water is separated from the coast by a band of fresher warm water derived from land drainage, and that the coldest water in the current lies at a depth of about one hundred metres A further comparison with sections of the current taken some years ago in Davis Strait shows that the current keeps practically the same temperatures and salinities throughout A cross section in Davis Strait gives 10 square miles of water below 0° C, and a cross section off Sandwich Bay in the south of Labrador gives a comparable figure of 12 45 miles The temperature of the body of the current (−1° to −1 5° C) is maintained by scanty solar warming, the shortness of the summer, and the melting of bergs and floes, which hinder any rise in temperature Mr Iselin points out how the water supply from the surface of Labrador supplies an urge for the current, just as he believes that the chief source of the current is the urge supplied in Baffin Bay by land drainage and the northward setting West Greenland current Low salinity, in spite of low temperature, gives a reduced salinity on the west of the bay The eastern side has a higher salinity by the inflow of Atlantic water This difference forces the western waters southward

Magnetic Analysis of α-Rays—An article by S Rosenblum in the December number of the *Journal de Physique*, on recent progress in the study of the magnetic spectra of α rays, contains some details of the apparatus by means of which he was able to show that certain α rays, for a long time accepted as simple actually consisted of discrete groups The magnet employed was the large one of the Paris Academy of Sciences The largest pair of pole pieces used had a diameter of 75 cm, and gave a constant field of 24,000 gauss over a region 35 cm in diameter, which was adequate to enable him to apply to α particles the focusing method with large deviations that had already been used with much success with β particles by Ellis, Meitner, and others The paper contains several interesting photographs of apparatus, as well as a number of reproductions of the magnetic spectra of the α rays from thorium C

Past and Future in Quantum Mechanics—In a short communication appearing in the second March issue of the *Physical Review*, Prof A Einstein, R C Tolman, and B Podolsky have raised the question of whether or not the quantum mechanics limits knowledge of the past path of a particle in the same way that it does knowledge of its future The test is made by consideration of an idealised experiment of a type now familiar in demonstrations of the uncertainty principle The history of two particles proceeding from one region of space to another by different routes is followed out in detail, and, to avoid a paradox in connexion with measurement of time and energy, it is first shown that momentum cannot be determined without changing its value, and then the original problem is decided in the negative A final remark is added to the effect that it is desirable to emphasise that quantum mechanics imposes limitations on the localisation in time of a macroscopic phenomenon like the opening and closing of a shutter

Reduction of Potassium Perrhenate—Noddack, one of the discoverers of the new element rhenium, found that the yellow oxide, Re_2O_7, when heated in sulphur dioxide, was reduced to a blue oxide of indefinite composition, and this when heated in

hydrogen gave a black oxide ReO_2. This was not obtained with milder reducing agents on a perrhenate solution, these yielding a yellow solution which when made alkaline with barium hydroxide gave a yellow precipitate believed to be barium rhenate. The yellow solution was believed by Noddack to be rhenic acid. In the March number of the *Journal of the Chemical Society* Briscoe, Robinson, and Stoddart describe experiments which show that the first light coloured product of reduction is a colloidal suspension of the black material which it afterwards yields. This black product is $ReO_2 \cdot 2H_2O$, and can be obtained quantitatively from the perrhenate, a reaction reminiscent of that by which the black reduction product of osmic acid, namely, $OsO_2 \cdot 2H_2O$, is produced. No evidence of the formation of rhenic acid or the precipitation of barium rhenate was obtained. The action of various reducing agents under varying conditions is described in the paper. The hydrate $ReO_2 \cdot 2H_2O$ when heated at 250° for twelve hours in an evacuated tube gave the anhydrous oxide, ReO_2, in the pure state.

Cosmic Rays.—M. F. Baldet contributes to *L'Astronomie* for March an interesting review of the progress of knowledge about these rays. So far back as 1903, Rutherford and McLennan had noticed the tendency of electroscopes to lose their charge; they thought that this might arise from gamma rays of terrestrial origin. To test this, an electroscope was carried up to a great height by a free balloon in 1910; it was found that the loss of charge was more rapid than on the ground, suggesting that the rays had a cosmic origin. Prof. Millikan discovered in 1913 their remarkable penetrating power, finding that it needed 20.8 metres of water or 1.8 of lead to quench them. It was inferred that their wave-length was only 1/50 of that of the gamma rays. It was shown that the rays did not come from the sun, since there was no appreciable difference between the strength by day and by night. When Prof. Størmer traced auroræ to the impact of electrons from the sun, it was thought that these rays might arise in a similar manner; accordingly Prof. Millikan made an expedition last year to Hudson's Bay, near the magnetic pole; there were bright auroræ on three nights, but the strength of the cosmic rays was no stronger than at Pasadena. It was concluded that they are not connected with the aurora. A slight tendency has been found for the strength of the rays to vary with the barometer; this is explained by atmospheric absorption, since the barometer measures the mass of air above the place. M. Baldet goes on to explain Prof. Millikan's suggestion that these rays may have their origin in the coming together of hydrogen atoms in space to build up more complex atoms; such transformations would be accompanied by an emission of energy. Sir James Jeans prefers to explain them by the annihilation of protons and electrons, showing that this would give rays of the right wave-length.

The Antimony Electrode.—The electrode consisting of metallic antimony in a solution containing solid antimonous oxide (Sb, Sb_2O_3) has been used in electrometric titrations and can be applied in cases where the hydrogen and quinhydrone electrodes do not function satisfactorily. It has also been used to measure pH values. In the March number of the *Journal of the Chemical Society*, Britton and Robinson describe experiments made with the object of determining the scope of the electrode as a titrimetric indicator and the extent to which the electromotive forces may be accurately converted into pH values, previous researches on the latter not being in good agreement. The work dealt with acids (including hydrocyanic acid) and salts which could not be titrated in the presence of the hydrogen or quinhydrone electrode. The results show that the antimony electrode possesses a wide range of applicability and is capable of rapidly indicating prevailing pH values with a moderately high degree of accuracy. A single universal buffer solution was employed, composed (according to the work of Prideaux and Ward) of a mixture of phosphoric, phenylacetic, and boric acids, each 0.04 molar, neutralised with 0.2 normal sodium hydroxide. Rods of pure cast antimony, cleaned with emery paper at the beginning of each titration, and purified antimonous oxide added to the buffer solution, were used, but it was found that addition of the oxide was unnecessary. Vigorous mechanical stirring is essential.

Flame Temperatures.—Jones, Lewis, Friauf and Perrott in the March number of the *Journal of the American Chemical Society* record measurements of the temperatures of hydrocarbon flames made at the Pittsburgh station of the U.S. Bureau of Mines. The method used was the reversal of spectrum lines of sodium and lithium salts in the flame, a heated tungsten strip examined by an optical pyrometer providing the light transmitted through the flame. The flame temperature increases rapidly, starting with a mixture near the lower limit of inflammability, and reaches a maximum with a gas-air mixture containing combustible slightly in excess (due to dissociation of the products) of that requisite to consume all the oxygen present. With further increase in percentage of combustible the flame temperature falls again, although not so sharply as for mixtures containing excess oxygen. The maximum flame temperatures of the gases tested vary from 1880° for methane to 1975° for ethylene; the maximum variation for the different hydrocarbons is less than 100°. The maximum flame temperatures of the unsaturated hydrocarbons (ethylene, propylene, butylene) are higher than those of the saturated hydrocarbons (methane, ethane, propane, butane, isobutane). The combustible-gas-air mixture which gives the highest flame temperature does not correspond to that which gives the highest speed of uniform propagation of flame, except for methane and possibly Pittsburgh natural gas. In other cases the mixtures for highest flame temperature contain less combustible gas. Attempts to calculate the flame temperatures, making use of specific heats, gave satisfactory results, the temperatures being 100° higher for the unsaturated and 40°–70° higher for the saturated hydrocarbons, in such a direction as to account for the difference by radiation losses from the flame.

Deformation of a Single Crystal of Silver.—A normal sample of silver consisting of an aggregate of crystals when worked and annealed is known to twin readily. This metal was, therefore, chosen by Gough and Cox (Institute of Metals, annual general meeting, Mar. 11) to investigate the formation of such twins in a single crystal. After being subjected to alternating torsional stress, however, no definite twin markings were to be observed, though the surface was covered by slip-bands on octahedral planes and in good agreement with the maximum shear stress hypothesis of elastic failure. After complete fracture, the specimen was vacuum annealed without, however, any twins being produced. Under compressional stress, both static and dynamic, the same result was obtained. The complete failure to produce twins in these experiments must be held to constitute proof of an essential difference of the mode of deformation between the single crystal and an aggregate.

Climatological Literature and Research

PROF. R. DeC. WARD'S recent paper, entitled "The Literature of Climatology"[1] deserves to be brought to the notice of English readers. It is an attempt, in so few as eighteen pages, at a survey of the various lines along which climatological research has been carried out, and of the literature available in each branch. There are a number of branches of science—for example, biology, medicine, and engineering—in which a research worker is sometimes confronted with the need for information about the climates of different parts of the world, and the precise kind of information required varies with the nature of the research work that is being done.

Prof. Ward tells us that the number of inquirers seeking the kind of information that his survey attempts to supply is greater among workers in subjects not obviously connected with climatology than among meteorologists and climatologists. Their special requirements are many. In agricultural science, soil temperature, the water content of soils, the extent to which the moisture present in the air as invisible vapour falls below the amount required to produce saturation, and the desiccating power of the air, may all be of particular interest. It is important for the inquirer to know whether any or all of these items have been studied, and, if so, where the necessary books of reference are to be found. The anthropologists, with their curiosity about past climates, must follow up a different branch of climatology with a literature of its own.

Prof. Ward is known on the eastern side of the Atlantic for his excellent work on American climates; he may become even better known if he will call in the aid of the official librarians of different countries, and produce the comprehensive survey of which his present paper might well form the nucleus. In an addendum to the paper, the author admits the consciousness that he has done his work with a certain degree of sketchiness—that is a feature of the paper that most meteorologists will undoubtedly notice. But until the thorough cataloguing of the available literature has been done in combination with a judicious weeding out of the unreliable or unsuitable works, few are likely to judge of the extent to which this fault is present.

A recent paper by Dr. C. Braak[2] is an example of meteorological literature of importance outside climatology. The requirements of horticulture have no doubt influenced the course of meteorological study in Holland, and most of the information given in Dr. Braak's paper is of practical importance to nurserymen, who are very much concerned with minimising frost damage, and must take advantage of any available knowledge about the average annual march of temperature both in the air and in the ground, and of the abnormalities of this seasonal march that may be expected to occur in particular years. Dr. Braak's paper is supplementary to an earlier paper by Ch. M. A. Hartman, No. 24 of the same series of publications, in which air temperature alone was considered. Dr. Braak deals, however, with earth as well as air temperature.

In regard to air temperature, the author's discussion is on the customary lines. He does not omit to give statistics in regard to the earliest and latest dates of frost. There is little that calls for criticism in these studies, unless one may be allowed to cavil at a minor point of interpretation of certain statistics in relation to the amount of water vapour in the atmosphere and to the occurrence of night frosts. Dr. Braak found that the average vapour pressure on nights of frost at each of thirteen representative stations was greatest for stations nearest to the coast, and diminished on passing inland. For example, the mean value was 5.6 millibars at Winterswijk and 7.1 millibars at Katwijk, the first named being an inland station, and the last named a coastal one. This is cited as evidence that the distribution of water vapour is of importance in determining the distribution of frost frequency.

Now it is well established that dryness of the atmosphere up to a considerable height favours a rapid fall of temperature at night under a clear sky, but it seems doubtful whether these statistics can be said to prove it. If the interior had sharper frosts than the coast for some other reason, would not the greater fall of temperature ensure a lower vapour pressure as measured near the ground through the greater condensation of hoar frost or fog? It must be remembered that on still and initially clear nights temperature generally falls below the value corresponding with the dew point at sunset and condensation of some kind invariably takes place, provided that the sky remains clear and the wind light. The condensed moisture is partly derived from the air, and the water vapour is thereby reduced.

The section dealing with earth temperature gives far more information on this subject than is to be found in most text books of meteorology. Using the equation

$$a_p = a e^{-p\sqrt{\frac{\pi}{kT}}}$$

where a_p is the amplitude of the periodic variation of period T at a depth p in the ground, and k is the thermal diffusivity given in terms of the depth of soil which can be warmed 1° C. by the heat passing in unit time (here 1 minute) through a layer of soil 1 cm. deep across which a constant difference of 1° C. is maintained, the thermal diffusivity of different soils at De Bilt, Wageningen, and Groningen are examined. The results are compared with similar information given for soils of the same type in Hann's well known "Lehrbuch". The agreement is not close, but the Dutch observations are reasonably consistent among themselves, and the above mentioned divergences may safely be referred to probable differences between the soils in the two sets of observations. The well known effect of aeration of the soil is brought out clearly: for a mixture of sand and peat, k was found to be 0.086 cm. at Groningen, and at the same place for a relatively compact and air free mixture of clay and sand k was 0.482. For peat and sandy clay, Hann gives 0.133 and 0.816 respectively. It is generally recognised that the conductivity of a particular soil is greatly affected not only by the amount of air contained in it but also by its water content and by other factors, which provide additional sources of divergence when closely similar soils are compared at different times.

In conclusion attention may be directed to interesting curves of air and soil temperature in the severe frosts of January-February 1917 and February 1929, on page 55. It is notable how, when the soil is frozen to some depth, the action of the latent heat of fusion of ice during a thaw destroys the normally good general agreement between curves of air temperature and soil temperature at a depth of less than 1 foot, and excellent examples are to be found in these curves. The same applies when freezing is taking place.

The National Institute of Industrial Psychology

THE tenth annual Report of the National Institute of Industrial Psychology, as we have already indicated (May 2, p 679), shows steady development of the work of the Institute, despite the prevalent industrial depression Among the industrial investigations undertaken by the Institute in 1930 were time studies of the various operations of machine moulding in aluminium works, which have led not only to considerable savings in time but also to improvements in the working conditions, particularly in ventilation Similar results have attended investigations in a calico dyeing and printing works, whilst studies of packing in a chocolate works led to the design of a new bench which increased output by 10 per cent, and also to the introduction of an improved packing method Other problems examined relate to internal transport in a cotton doubling mill, and the Institute's investigations have been responsible for improvements in the organisation of such varied types of factories as gas works, engineering works a potted meat and fish paste factory, radio works, rubber products factory, spinning mill, wireless and cable offices, oil distribution company During the year, investigations conducted for the railways resulted in valuable recommendations for eliminating accidents in goods shunting and for reducing pilfering and damage to goods

A feature of the industrial investigations of the Institute during 1930 is, however, the extent to which it has been called upon to apply its experience and methods of vocational selection to the solution of problems concerning personnel Contributions of this kind have been made in the recruitment of staff for chemical works, cleaning works the selection of telephone operators for the G P O, as well as in the selection of general staff for insurance offices and retail stores It is thus evident that the value of the research in the field of vocational guidance already carried out by the Institute is now widely recognised, and the account of the Institute's Carnegie experiment, to be published under the title of Methods of Choosing a Career ", should be assured of a wide reading

Research work is being carried out in this field in association with the Juvenile Employment Department of the Birmingham Education Committee to determine the applicability of the Institute's methods in the Borstal institutions The Fife Carnegie experiment in vocational guidance has continued in co-operation with the Medical Department of the Fife Education Authority and with the Juvenile Advisory Committee of the Employment Exchange, whilst other members of the research staff are attempting to follow up private vocational guidance cases and to prepare occupational analyses for the use of the vocational guidance section Some of the research on industrial psychology in progress at the Universities of Cambridge, London, Leeds, Durham (Armstrong College), Edinburgh, Glasgow, Aberdeen, and St Andrews is itself definitely related to vocational guidance or selection Examples are the studies of vocational guidance in the Cambridge area carried out by Mrs Ramsay, of employment psychology at Durham, educational psychology at Leeds, on perseverance and character at King's College, London, and on the testing of printers' apprentices at Edinburgh

The Institute of Industrial Psychology is itself responsible for research on the nature and measurement of the mental abilities involved in various types of factory assembly operations, on colour discrimination, on daily fluctuations in industrial efficiency, and on occupational prospects for boys, based on a representative group of 500 working boys, employed and unemployed An investigation conducted by Dr Pinard elaborated tests for perseveration which have facilitated a division of people into three and not into two classes as required by Jung's theory, and are now being applied for the selection of good leaders A research on methods of diagnosing social ability, especially the capacity to 'handle' people has been commenced, and investigations which have led to the elaboration of standardised tests for motor drivers have attracted a considerable amount of interest

Not the least important feature of the Institute's work is that which it has carried out on behalf of the National Institute for the Blind (more particularly during the past year), its studies of the organisation, working methods, and conditions of various blind workshops The interest of this work lies not so much in its remarkable effect in increasing efficiency in such workshops, but in the extent to which it assists the blind to become useful and effective members of the community and breaks down the isolation so characteristic of the blind worker

The Microscope and the Paint Industry

THE value of the microscope in the study of pigments is being increasingly realised by the British paint industry, also in Germany and elsewhere It has long been known that chemical analysis alone was quite insufficient for evaluating the true properties of a pigment, but that particle size and shape are, among other things, of very great importance, especially in determining the nature and extent of the reaction, for example, between the pigment and an oil medium like linseed oil

In a recent article in the *Farben Zeitung* (Mar 7, 1931), Dr A V Blom describes the results of an examination of red lead by a polariscope with crossed nicols One of his principal findings was that the reactivity of the red lead with linseed oil depended not only on the size of the particles but also on their shape, and that even particles of the same form varied in this respect He distinguished at least six different forms and conditions of particle, of which the first is smooth and crystalline, and not readily affected by linseed oil, the second is small and spherical, and the others are more or less oxidised varieties of the first or second The most recent research in crystal growth has shown that atoms are most active at their edges and corners, also that crystals are made up of blocks or sections separated from one another by submicroscopic channels Surface energy is not, therefore, uniformly distributed in a crystal, but varies with its molecular density, and the critical energy increment of the surface reaction may vary considerably in one and the same crystal In the case of red lead, linseed oil only enters into reaction where it is in direct contact with the lead oxide surface, forming lead soap or linoleate These soap molecules also occur in many different forms, including the colloidal, in which case they would not be seen between crossed nicols

It was found that a 100 per cent red lead from which all free lead oxide had been removed by careful and repeated extraction with ammonium acetate solution was changed quantitatively in the course of two years into non isotropic spherical crystals if it was in contact with pure linoleic acid In commercial red leads, all these various forms of particles are found in widely differing proportions, causing correspondingly wide differences in the qualities of the red lead

University and Educational Intelligence.

CAMBRIDGE.—The General Board has appointed Dr. H. Jeffreys, of St. John's College, reader in geophysics.

The Council of the Senate has recommended that it be authorised to inform the Plummer Trustees that the University would approve of the establishment in the University, on the John Humphrey Plummer Foundation, of professorships of inorganic chemistry, of mathematical physics, and of colloid science, and of an annual payment at the initial rate of £300 from the Plummer Fund towards the maintenance of the Department of Colloid Science.

The Council of the Senate has issued a report on the proposed allocation of the Rockefeller benefaction. In 1928, the International Education Board offered to provide a sum not exceeding £700,000, provided that the University obtained from other sources the balance of £479,000 necessary to put the scheme into operation. At his installation last year, the Chancellor announced that the University had received promises which would enable it to satisfy this condition. The complete scheme consists of two parts, one dealing with the University Library involving a capital sum of £500,000, and the other dealing with scientific developments involving a capital sum of £679,000.

On the scientific side of the Rockefeller scheme, money is to be received from the International Education Board *pro rata* as it has been collected and paid in from outside sources or guaranteed by the University. At present, the University has received approximately £110,000 from outside sources and £210,000 from the International Education Board. The income of the sums already in hand will be about £15,000. In the opinion of the Council of the Senate, this income is sufficient to finance those parts of the Rockefeller scheme which the heads of departments think can now suitably be put in hand, provided that the professorship of mathematical physics and a professorship of colloid science (to replace the temporary professorship of colloidal physics) are financed from the Plummer Foundation. The Council has accordingly recommended that the General Board be requested to take the necessary steps to bring into operation, by Oct. 1, 1931, so much of the scheme as can be carried out under present conditions.

EDINBURGH.—The University Court, at its meeting on April 27, resolved to appoint as the first professor of geography, Mr. Alan G. Ogilvie, at present reader in geography at the University, the appointment to begin from Oct. 1, 1931. The foundation of this new chair has been made possible by a grant from the Carnegie Trustees and funds collected by public subscription through the action of the Royal Scottish Geographical Society.

LONDON.—Prof. Max Jakob is giving a course of four lectures on "Steam Research in Europe and in America", at the Institution of Civil Engineers, on May 7, 8, 14, and 15 at 5.30 P.M. The lecture on May 14 will deal with optical measurements—theories and thermodynamical evaluation and control of the results of experimental work, and that on May 15 with special thermal properties and processes of water and steam, and a note on international steam table conferences and international steam tables. Admission to these lectures is free, without ticket.

OXFORD.—The debate on the enlargement and improvement of library facilities in Oxford has been postponed to May 19; the voting on the actual decree to take place on May 26. In each of the schemes now before Congregation, the addition is advocated of a new wing to the Radcliffe Science Library.

The Rhodes Memorial lectures will be delivered in German, on May 9, 16, and 23, by Prof. A. Einstein, on "The Theory of Relativity".

APPLICATIONS for a Ramsay Memorial Fellowship for Chemical Research will be considered at the end of June next. The fellowship will be of the annual value of £250, with a possible additional sum of not more than £50 per annum for expenses. The tenure of the fellowship will be two years, but it may be extended for a third year. Applications should be sent not later than June 5 to the Secretary, Ramsay Memorial Fellowships Trust, University College, Gower Street, W.C.1.

UNIVERSITY COLLEGE, London, in its recently published report for the year ending February 1931, records the closing, as from July 31, 1930, of the College Centenary Appeal Fund, which was inaugurated in 1925. The appeal was for £500,000 and towards this a sum of £227,764 was raised. Among the departments for the development of which contributions from the fund have been made are those of chemical engineering and zoology. To the former has been allocated more than £60,000, the full amount appealed for in 1925; but meanwhile the position and needs of the department have been reviewed by a special committee over which the late Lord Melchett presided and a further sum of £110,000 will be needed to give effect to this committee's scheme. For the department of zoology, the appeal asked for £50,000, but the International Education Board interested itself in the matter and offered to pay half the cost of a wider scheme involving an expenditure of £240,000. The question of ways and means for qualifying for this gift is now engaging the attention of the College Committee. The total number of students registered last session is 3150, as against 3249 the preceding year. The decrease is more than accounted for by the fact that there was in 1929 no vacation course in spoken English for foreign students, the attendance at which normally exceeds two hundred.

Birthdays and Research Centres.

May 9.—SIR JAMES IRVINE, F.R.S., Principal and Vice-Chancellor of the University of St. Andrews.

In large measure through the adoption of methods developed in my earlier researches on sugars, the structural chemistry of carbohydrates has been greatly expanded during the past thirty years. The progress is gratifying, yet, after all, it must be admitted that these advances, which enable us to ascribe structural formulæ to representative carbohydrates, do not lead very far towards the interpretation of fundamental problems.

So many questions remain unanswered. Is glucose the first product of photosynthesis? Why are sugars optically active, and why is the glucose configuration favoured above all others? By what processes are the hexoses converted one into the other? What is sucrose and how is it formed? These are but examples. If I had my scientific life to live over again, I would study these additional problems, but would do so under conditions approximating to those which prevail in plant and animal life. If it be the case that "even a paramecium is not quite himself under the fierce light which beats on the microscope stage", it is equally true that a sugar is unlikely to reveal its true characteristics when exposed to the fierce reagents of the organic chemist.

Societies and Academies

LONDON

Royal Society, April 30 —**A E H Tutton** Determination of the yard in wave lengths of light The author has carried out a determination of the number of wave lengths of the red light radiations of hydrogen (H_α) and cadmium (Cd_r), and of the yellow radiations of neon (Ne_c), in the British Imperial Standard Yard, by an original method The Imperial Standard Yard, at the official temperature 62° Fahrenheit and 760 mm barometric pressure, is found to comprise 1,420,210 3 wave lengths of the standard red lines of cadmium, Cd_r, 1,562,408 6 wave lengths of the yellow neon line Ne_c and 1,393,266 5 wave lengths of the red hydrogen line H_α Instead of relying on direct determinations with cadmium light, to produce which the vacuum tube has to be heated to 340° C which was found gravely to affect the thermal equilibrium and thereby the accuracy of the observations, the direct determinations with H_α (which is very close to Cd_r) and Ne_c were used to calculate the value for Cd_r, the two independent values thus obtained for Cd_r were 1,420,210 8 and 1 420,209 8, an agreement which gives every confidence that the round number 1,420,210 is very near the truth It is suggested that this round number might be taken as the length of the British yard —**U R Evans, L C Bannister, and S C Britton** The velocity of corrosion from the electrochemical standpoint By excluding oxygen from the anodic areas, it has been found possible to tap and measure the whole of the electric current responsible for the corrosion of iron, and to show that the whole attack is of an electrochemical character The current can never exceed that limiting value which would cause so much polarisation as to make the cathodic and anodic potentials equal, such 'equipotential' conditions are closely approached at high salt concentrations Most of the polarisation occurs at the cathodic area The law governing the ratio of anodic and cathodic areas is that the anodic area extends until the cathodic current density reaches the 'protective value' requisite to prevent further extension —**T L Eckersley** On the connexion between the ray theory of electric waves and dynamics There is a very close analogy between the analytical description of the transmission of such electromagnetic waves and Schrödinger's wave theory of quantum dynamics Optical ray methods are often used in the analysis of wireless wave transmission and the rays can be given a dynamical interpretation as the orbits of a group of waves (considered as a particle) The approximate ray method of analysis bears the same relationship to the true wave method that the Newtonian dynamics bears to the new wave mechanics The theory can be applied to the transmission of waves between the earth and Heaviside layer and approximate solutions obtained which, in the particular case of a well defined conducting layer give G N Watson's value of the attenuation coefficient The solutions, like the older Bohr Sommerfeld quantum solution, are incomplete, giving the direction cosines and attenuation coefficients, but not the amplitudes The method, however, can be applied to a wide variety of cases —**Lord Rayleigh** On a night sky of exceptional brightness, and on the distinction between the polar aurora and the night sky An exceptionally bright night sky on Nov 8, 1929, is described, with photometric observations It was of about four times the ordinary brightness and eight times the minimum ever observed It was of the same chromatic constitution as usual, and the aurora line was not conspicuous There was no accompanying magnetic disturbance Spectra of the aurora and of the normal night sky are reproduced for comparison Nitrogen bands are absent in the latter Two unidentified bright lines in the night sky spectrum are remeasured The wave lengths found are 4419 and 4168 —**T H Havelock** The wave resistance of a spheroid It is shown how to calculate the wave resistance of an ellipsoid submerged in water and moving horizontally in any orientation Explicit results are given for prolate and oblate spheroids moving in the direction of the axis of symmetry and at right angles to that axis —**O W Richardson and P M Davidson** The spectrum of H_2 The bands ending in $2p\,^3\Pi$ levels The bands of the H_2 spectrum are described which start on the levels $3d\,^3\Sigma$, $3d\,^3\Pi_{ab}$, $3d\,^3\Delta_{ab}$, $4d\,^3\Sigma$, $4d\,^3\Pi_{ab}$, $4d\,^3\Delta_{ba}$ and end in $2p\,^3\Pi_{ab}$ The upper levels show pronounced uncoupling phenomena, and their properties are otherwise similar to those of the corresponding singlet levels of H_2 and also to those of the $d\,^3\Sigma$, $d\,^3\Pi$, and $d\,^3\Delta$ levels of He_2 The $3d\,^3\Sigma \rightarrow 2p\,^3\Pi$ bands show a strong Zeeman response, just as do the $3d\,^1\Sigma \rightarrow 2p\pi\,^1\Sigma$ bands The constants of the final Π levels, common to all the bands, are in good agreement with the supposition that this is the continuation at $n = 2$ of the upper levels of the α, p, λ bands for which $n - 3$, 4, and 5 —**C M M Dowell and F L Usher** Viscosity and rigidity in suspensions of fine particles (1, 2) In lyophobic suspensions of charged particles in an aqueous liquid, variation of viscosity with rate of shear is dependent on the formation of aggregates, whilst rigidity depends on the linking of the aggregates to form a continuous structure Measurements of rigidity and of viscosity in relation to rate of shear were also made in suspensions of uncharged particles in inert organic liquids of the same density as the solid, in conjunction with microscopic observations Photomicrographs show the existence of aggregates and structures or their absence, accordingly as the suspensions exhibit or fail to exhibit variable viscosity and rigidity

FRIDAY, MAY 15

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 4—Sir Arthur Keith Human Monsters and Malformations (6) A Consideration of the Commoner Malformations to ascertain how far they can be explained by regarding them as Atavistic States or as due to Parental Influences.

ROYAL SOCIETY OF ARTS (Indian Section), at 4 30—F S Grimston The Indian Ordnance Factories and their Influence on Industry

BRITISH INSTITUTE OF RADIOLOGY (Medical Meeting), at 5.

PHYSICAL SOCIETY (at Science Museum, South Kensington), at 5 15—Sir Richard T Glazebrook Standards of Measurement their History and Development (Guthrie Lecture).

INSTITUTE OF CHEMISTRY (Belfast and District Section) (at Royal Belfast Academical Institution), at 7 30.—Annual General Meeting

ROYAL SOCIETY OF MEDICINE (Obstetrics and Gynæcology Section) (Annual General Meeting), at 8.—The Relative Value of the Induction of Premature Labour, Test Labour, and Cæsarean Section in the Treatment of Minor Degrees of Contracted Pelvis.

ROYAL INSTITUTION OF GREAT BRITAIN, at 9—Prof J C Philip Experimental Aspects of Hydrogen Ion Concentration

SATURDAY, MAY 16

INSTITUTION OF MUNICIPAL AND COUNTY ENGINEERS (Southern District Meeting) (at Cheltenham), at 10 30 A M

PUBLIC LECTURES

FRIDAY, MAY 8

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE (Public Health Division), at 2—Dr J J Buchan Industrial Hygiene The Rôle of the M O H

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE (Public Health Division), at 5—Sir George Newman The Rise of Preventive Medicine (Heath Clark Lectures) (5)

MONDAY, MAY 11

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE (Public Health Division), at 5—Dr C F White Port Work

TUESDAY, MAY 12

LONDON SCHOOL OF ECONOMICS, at 5—Prof L. Hogben Some Aspects of Human Inheritance (8) Mental Inheritance

INSTITUTE OF PATHOLOGY AND RESEARCH (St Mary's Hospital W 2), at 5—Prof C A Ariens Kappers The Function of the Various Layers of the Cortex

WEDNESDAY, MAY 13

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE (Public Health Division) at 5—Dr B Hart Mental Hygiene

ST THOMAS'S HOSPITAL, at 5 30—Prof G Grey Turner Resection of the Rectum (Succeeding Lecture on May 15)

THURSDAY, MAY 14

GUY'S HOSPITAL MEDICAL SCHOOL at 5—Prof W R Sorley Science and Morals (Fison Memorial Lecture).

NATIONAL HOSPITAL FOR DISEASES OF THE HEART, at 5—Sir Thomas Lewis Ischæmia of Muscle as a Cause of Anginal Pain (St Cyres Lecture).

FRIDAY, MAY 15

LONDON SCHOOL OF ECONOMICS at 5—Lord Lugard of Abinger British Rule in Tropical Africa (Succeeding Lectures on May 18 and 19)

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE (Public Health Division), at 5—Prof E L Collis Industrial Hygiene Respiratory Diseases

IMPERIAL COLLEGE—ROYAL SCHOOL OF MINES, at 5 30—Dr H de Bockh Selected Chapters of Regional Geology and Tectonics (Succeeding Lectures on May 19 and 21)

KING'S COLLEGE LONDON at 5 30—Col the Master of Sempill Air Communications of the British Empire

INSTITUTION OF MECHANICAL ENGINEERS, at 8—Prof E L Collis The Coal Miner His Health and Occupational Diseases (1) Environment of Work (Chadwick Lecture)

ANNUAL MEETING

MAY 7 AND 8

IRON AND STEEL INSTITUTE (at Institution of Civil Engineers) at 10 A M

Friday May 8, at 10 A M—General Meeting

Announcement of the award of the Andrew Carnegie Research Scholarships for 1931-32

Announcement of the award of the Carnegie Gold Medal to Dr E Valenta.

Announcement of the award of the Williams Prize to F Bainbridge

Dr W Rosenhain and A J Murphy Accelerated Cracking of Mild Steel (Boiler Plate) under Repeated Bending

H J Gough and A J Murphy On the Nature of Defective Laminations in Wrought-Iron Bars and Chain Links

A L Norbury and E Morgan The Effect of Carbon and Silicon on the Growth and Scaling of Grey Cast Iron

At 2 30—V Harbord The Basic Process Some Considerations of its Possibilities in England

E C Evans L Reeve, and M A. Vernon Blast-Furnace Data and their Correlation—Part II

C O Bannister and W D Jones The Sub-Crystalline Structure of Ferrite

C H M Jenkins and H J Tapsell Some Alloys for Use at High Temperatures Complex Iron Nickel Chromium Alloys. Part III—The Effect of Composition and Exposure to High Temperatures

Papers to be presented and discussed by correspondence—

Sir H C H Carpenter and J M Robertson The Formation of Ferrite from Austenite.

J H Chesters and W J Rees Refractory Materials for the Induction Furnace.

Dr J Newton Friend and W West The Resistance of Copper Nickel Steels to Sea Action.

E Ohman X Ray Investigations on the Crystal Structure of Hardened Steel

G Phragmén: X Ray Investigation of Certain Nickel Steels of Low Thermal Expansion.

SATURDAY, MAY 16, 1931.

Forestry Research in Great Britain

IN days gone by, research work in connexion with forestry was regarded by the average forest officer, whether administrative or executive in grade, as of little practical value , only by the few was the idea even held that such work might have an academic value That this was the accepted point of view throughout the greater part of last century can be readily ascertained by studying the work of the various forestry departments in European countries Outside Europe, India and Japan may be instanced as examples where the same ideas prevailed amongst senior forest officers

The dawn of the twentieth century witnessed the beginnings of a change of opinion in some of the more efficiently managed forest departments in Europe The awakening came slowly, and cannot be attributed to any one set of factors Greater demands for timber and other forest products, more intensive working of the forests, the larger areas of artificially formed forests, and the introduction and increase in areas of plantations of exotics, especially coniferous species - all of these may be said to have aroused interest in, and shown the necessity for, research work The recognition resulted in the establishment of research centres or departments in several European countries, either in connexion with universities where forestry schools were in existence or in strengthening the pure science branches of the existing forest schools

It was, however, one of the outcomes of the War which may be said to have given the greatest impetus to forest research work in Europe, as was the case in India, though the chief causes in the two instances were to some extent dissimilar The greatly increased costs in connexion with forest work of all kinds necessitated a reduction, or elimination, where possible, of all waste According to locality factors, climate, species dealt with, and so forth, a set of problems were presented to the forest administration which demanded a solution, the underlying financial idea being the production of forest crops yielding a larger volume of material on a smaller area or in a shorter space of time than had been the case in the past, or on poor quality land not under forests

These types of problems have a varying importance for the research officer, depending upon the nature of the forest in question, whether indigenous or not The matter becomes of the first importance, however, when (1) exotics, especially conifers in Europe, are being employed on a large scale to reafforest areas formerly occupied by indigenous

forest, (2) where bare lands, which have been for long unforested, and may or may not have carried forest before, are being planted on a wholesale scale, whether with indigenous or exotic species—the latter usually with the expressed or implied wish or hope that a larger volume of material will be produced per unit of area in a shorter space of time than is the case with an indigenous species

The officers responsible for the introduction of the policy implied under (1) and (2) are the administrative forest officers, the executive officers carrying it out Until comparatively recently, the research officer, if he existed, has had no voice in formulating an afforestation or reafforestation policy, nor was he often consulted with reference to the species to be made use of in afforesting bare lands, or in the choice between indigenous or exotic species The part of the research officer came into play when disease had made its appearance in the plantations formed under a preordained policy

Of late this position has been reversed in some of the countries of Europe Sweden may be quoted as an illustration, since it is common knowledge that the Swedish forests play a most important part in the economy of the nation, forest produce taking a high place in that country's export trade Apart from the ordinary work in regenerating the areas annually felled, Sweden has undertaken an extensive afforestation campaign on barren lands, of which large areas are of a varying type of peat As Dr Rayner has shown in her letter in NATURE of April 4, a close collaboration exists in Sweden between the pure science workers and forestry specialists at the research centres and the Swedish Forest Service To quote Dr Rayner's example ' the significance ', she points out "of mycorrhiza in nutrition, and the urgent need for laboratory research directed to promote control of its formation in new plantations, have long been matters of concern in the Swedish Forestry Service, and are becoming so in those of other countries, for example, in certain of the North American States In Great Britain and many parts of the Empire the matter is one of special interest and concern in view of the extensive afforestation of non woodland soils and the use of exotic tree species "

That research work would be necessary in connexion with an afforestation programme in Great Britain was realised by the framers of the 1919 Forestry Act, for under the powers given to the Forestry Commissioners was a clause "to conduct and assist research" In the interests of true research work (apart from its purely forestry aspects) it might have been better had the words ' to conduct ' been omitted from the above clause, and so have left research without the fetters of Government control more especially in the case of a new department with all to learn

In their Annual Report for the year ending Sept 30, 1925, in connexion with research and experiments, the Commissioners wrote "The work embraces the establishment and periodic measurement of permanent sample plots of growing timber, from which valuable data on the rate of growth and methods of thinning are being obtained, extensive nursery and plantation experiments directed towards the improvement of afforestation technique, entomological and mycological work on the protection of nursery stock and trees from insects and fungi, as well as botanical, physiological, and chemical work on subjects such as the establishment of trees in peaty soils" This work, it was said, was carried out by the Commission's experiment officers, "while allied laboratory work is conducted at the educational institutions which are in receipt of grants from the Commissioners"

It may be at once admitted that some valuable work of a purely professional nature—the maintenance of sample plots, the preparation of yield tables for several species, investigations into the importance of the origin of seed, preliminary work on the treatment of peaty soils, the issue of leaflets on certain common diseases, and so forth—has been accomplished during the first decade of the Forestry Commissioners' work They have also co operated with the Forest Products Research Board When, however, the question of pure research work and its value and importance to the future of forestry in Great Britain are considered, it cannot be said that the Commissioners have approached the matter from an unbiased point of view

The Commissioners commenced their work with the underlying idea that they were to be the sole arbiters on everything connected with forestry in Great Britain Up to a certain point this may have been sound In the case of true research the contrary was the case The research work to be carried out and the lines upon which it was to proceed were laid down by the Commissioners, and yet it is certain that they would be the first to admit that they laid no claim to be considered, as a body, men of scientific attainments Choice of work to be carried out, choice of centres at which certain parts were to be undertaken, all were laid down in the absence of a knowledge of the broader and vital aspects of the work envisaged—aspects the

importance of which, as is so well indicated by Dr Rayner's letter, can only be foreshadowed by the research worker Perhaps as fatal to progress of real value was the policy, so common to Government departments in the past, of concentrating the work desired either in a cadre of inevitably more or less inexperienced 'experiment officers' of their own, or of confining part of the work to centres selected on some narrow system of choice and without a definite knowledge of the work being carried out at other institutions in the country, perhaps already better equipped than the ones chosen and accorded grants

The next decade of the work of the Forestry Commissioners will be a momentous one The money to be spent in pure afforestation work on new lands runs to a considerable figure In this one instance it is becoming obvious that soil research work will perhaps be the deciding factor between success and failure The Commissioners will be well advised if they mobilise for this work every centre in the country—and they are but too few—capable of assisting in this vital matter A few more or less isolated investigations into peat areas barely touches upon the fringe of the soil investigation problem

If research work in forestry in Great Britain is to achieve progress and be of practical utility, it will be necessary to enthuse all research centres and pure science research specialists throughout the country, and the programmes of research, under the different aspects required (as indicated by the forestry authorities), should be drawn up by the scientific investigators involved In this way the principles and aims of forestry will become better understood by the latter, whilst the public will be assured, in so far as human agency can assure it, that the money being sunk in forestry is not being wasted

Scientific Inference

Scientific Inference By Dr Harold Jeffreys Pp vii + 247 (Cambridge At the University Press, 1931) 10*s* 6*d* net

SCIENTISTS generally care so little for scientific principles that the title of this book may repel as many as its author's name attracts Let it be, therefore, stated at once that it is not a formal treatise, but a collection of essays of which some have a value independent of the doctrines they illustrate Everyone with a logical mind will enjoy Chapters vii, viii, ix, in which it is shown how three great branches of mathematical physics, mensuration, Newtonian dynamics, light and relativity, can be developed concisely from the minimum of experimental fact, and everyone will find something novel and suggestive in Chapter x, on miscellaneous questions

However, the main purpose, indicated by the title, is to expound the views that the papers of Drs Jeffreys and Wrinch have made familiar to those who study the logic of science This view is explained generally in Chapter i Probability is the fundamental notion in scientific inference, all propositions have a comparable, and therefore measurable, 'probability on the data", general propositions cannot have high probability unless they are 'mathematically or logically simple" On these grounds it can be shown why the "classification of sensations" that science actually adopts is to be preferred to any other Chapters ii, iii, together with certain appendices, develop the necessary calculus, Chapters iv, v, vi apply it successively to quantitative laws, errors, physical magnitudes

Chapter ix, on other theories of scientific knowledge, will seem to many readers the most important of all For the feeling that discussions of scientific inference are necessarily barren is undoubtedly due to the contrast between the agreement concerning what is actually true in science and the disagreement concerning why it is true Whether Dr Jeffreys has succeeded at all in reducing this disagreement must be decided in the first instance by those whose theories he criticises But it is permissible to point out that he has noticed only theories with some similarity to his own, and that even if he abolished all discrepancies between these theories, there would still remain others who reject the most fundamental postulates from which his arguments start Prof Bridgman's theory belongs to this class, I think, my own certainly does perhaps I may show very briefly how completely irreconcilable our views are

I maintain that the only propositions that have a measurable probability are those concerned with the happening of future events of the kind that can be shown experimentally to possess a measurable chance, such propositions form a very small fraction of all scientific propositions * I maintain further that all scientific inference hangs on certain primary laws more fundamental than any that Dr Jeffreys has considered, and, in particular,

* Thus I deny that as Dr Jeffreys first postulate demands, the probability on the data of any one of the following three propositions is greater than, less than, or equal to that of any other —The year 1933 will be wetter than 1934, There is extra terrestrial life King Alfred is one of my ancestors The first will the second may, the third will not some day be known to be definitely true or false

that mathematical conceptions cannot be logically introduced into science until the non mathematical laws that underlie measurement (and its inevitably associated error) have been investigated

Can such extreme disagreement be resolved? If it cannot, what is the use of all this discussion? An obvious suggestion is that the disagreement arises from a preoccupation with one of the two distinct forms of scientific activity, experiment and explanation, to the exclusion of the other and that a thinker may arise some day, equally at home in the laboratory and in the study, who will weld these partial views into a single complete whole The first part of this suggestion may be accepted without the second, personally, I hold that certain outlooks are essentially antagonistic, that, outside the narrow bounds of pure science and pure mathematics, one man's truth may really be another man's error, and that mathematical science is the highest form of intellectual activity just because it permits co operation, and not mere toleration, between diverse minds But even if that is true, the discussions have some value At the lowest, they amuse those who take part in them, at the highest, they sometimes reveal an agreement in unexpected places, which should surely be regarded as peculiarly significant

If there were a generally accepted theory of scientific inference, it would probably have little influence in determining the course of scientific investigation, but it might have a great influence in determining the form in which conclusions were presented, particularly for instruction Scientific education might cease to be mere absorption of unco ordinated facts and become a training in precise thought That stage has not yet been reached, but some small steps towards it have been taken It is encouraging to find that even Dr Jeffreys and I can agree in condemning certain features of the theory of measurement that pervades our text books and it is not too optimistic to hope that our grandchildren will be taught the difference between fundamental and derived magnitudes and be no longer confused by nonsense about dimensions

NORMAN R CAMPBELL

Science and Parenthood

The Retreat from Parenthood By Jean Ayling Pp xvi+293 (London Kegan Paul and Co, Ltd, 1930) 10s 6d net

IN "The Retreat from Parenthood", the author makes a vehement plea for the application of science to life in all the small details of home comfort, child-rearing, and marital relations—a plea for the emancipation of these provinces from the domination of age old formulæ and customs It is suggested that the traditional machinery of home life is particularly ill adapted to the rearing of healthy and happy children, and that those more intelligent sections of the community typified by the professional classes will tend increasingly to curtail their reproductive activities unless biological ideals are applied to modern life It is an acknowledged and deplored fact that during the last twenty or thirty years the birth rate among the professional classes has fallen to an alarming extent The author examines the causes of this curtailment of fertility and her analysis makes depressing reading, indeed, if her diagnosis is correct, the vast majority of men and women of intelligence must be living most unhappy lives, dominated by the tyrannical inefficiency of modern life

In the first part of the book, a survey is made of the conditions in modern homes the practical difficulties connected with running homes in a world where science, while having revolutionised commerce, transport, production, and amusements, has scarcely, if at all, penetrated to the individual household, the unfitness of most men and women, by reason of their upbringing and incomplete education, for happy marriage and intelligent parenthood, the traditional shroud of mystery surrounding child-bearing, which prevents any but the most determined of women from obtaining the knowledge necessary to produce children without undue physical and mental injury to themselves and to their offspring the economic and social influences which in so many cases relegate the child bearing woman to a life entirely devoid of mental activities, with consequent harm to herself, the children, and conjugal relations

In the author's opinion, the most important factors determining the present decline in birth-rate in the professional classes are the prevalence of the idea that from the womb to the school door the needs of the child must be supplied within the family as a unit, the fact that, in so many cases, women determined to bear children have to pay the price of exile from professional fields, while women determined on a professional life-work have to pay the price of sterility If the provision of healthy and intelligent children is regarded as one of the most important services that any man or woman can render the community—and by a large section of our generation it is so regarded—then this penalisation of parenthood requires explana-

tion, especially since this obstructive attitude is directed particularly against those women who, by reason of sound physique, trained intelligence, and high ideals, are undeniably best fitted for maternity

The author maintains that, instead of adapting the biological needs of the race to professional regulations, it might be possible to adapt professional regulations to biological needs Accordingly, a scheme is outlined in the second half of the book for arresting the decline of birth rate among professional workers, taking due account of the factors at present predisposing to failure, whereby services would be provided by a co operative organisation to deal with all phases of child rearing Great stress is laid on the necessity for easily available, up to date medical supervision for the child from the moment of conception until it reaches school age

The book suffers from diffuseness, repetition, and, above all, from irritating mannerisms and a certain immaturity of style reminiscent of the college debating society But it is an illuminating account of the difficulties encountered by women attempting to conduct their parenthood in a sane and unsentimental way, and is a strong indictment of the progress of medical knowledge and availability of that knowledge on all matters concerned with pregnancy and child rearing The problems are difficult of solution and there is urgent need for organised research in this, as yet, almost virgin field But the author justly remarks "No one can visualise the splendour of man's material achievements without wondering why for so long the human race has neglected its own needs "

M A

The Wry-mouthed Feather-stars

Smithsonian Institution United States National Museum Bulletin 82 *A Monograph of the Existing Crinoids* By Austin Hobart Clark Vol 1 *The Comatulids* Part 3 *Superfamily Comasterida* Pp vii + 816 + 82 plates (Washington, D C Government Printing Office, 1931) 2 dollars

IT is ten years since the second part of this elaborate monograph was published, but, considering the enormous amount of detail here assembled after personal checking by the author, one cannot complain of undue delay

The unstalked crinoids herein discussed are those with the anus in the centre of the oral face and with the mouth consequently excentric Though all are included in a single family Comasteridæ (formerly Actinometridæ), they are here placed in a superfamily Comasterida The object of this conception, which we owe to Gislén, is to contrast them with the super families Tropiometrida and Mariametrida, which with the Comasterida make up the curiously named Oligophreata, one of the two sub-orders of the Comatulida The Comasteridæ again are subdivided into three sub families—Capillasterinæ, Comactiniinæ, and Comasterinæ, and these between them cover nineteen genera As moderately familiar examples we may mention *Comaster* itself, based by L Agassiz on *Comatula multiradiata* Lamarck, a species that has given occasion for much controversy and *Comatula* Lamarck, with genotype *C solaris*, of which *Actinometra* Muller and its genotype *A imperialis* are respectively synonyms These two species exemplify in intensified degree that variability which renders the identification of all these animals a task of perplexing difficulty, enhanced in practice by the mutilation of most available specimens Those confronted with the problem will be grateful to Dr Clark for his careful diagnoses and elaborate keys, which, as he says, should be followed very closely and literally

The more general worker will value the introduction, which traces the development of the scheme of classification adopted in the present monograph To that development the largest contributor has been Dr Clark himself in a long series of papers, of which summaries are here given Other writers, especially T Gislén, are also mentioned Besides this, the synonymics and references to literature at the head of each classificatory division give a brief précis of nearly every work cited In view of these remarkably complete and detailed references, it is not easy to understand why on pp 76 and 81 Dr Clark assigns the establishment of the family Actinometridæ to himself in 1907 That family, with Atelecrinidæ and Thaumatocrinidæ, was already defined in the Echinoderm volume of "A Treatise on Zoology", edited by Lankester in 1900

The numerous photographs of specimens reproduced in half tone on 82 plates (back to back) add to the appearance and weight of the volume and make one marvel the more at its remarkably low price It may, however, be doubted whether they are so useful for purposes of identification as the outline drawings of special structures used in previous volumes There is an index to systematic names, but a complete index to vol 1 is promised for part 5 We wish Dr Clark health and strength to complete his great work F A BATHER

A Survey of Television

(1) *Television To-day and To-morrow* By Sydney A Moseley and H J Barton Chapple Pp xxiii + 130 + 47 plates (London Sir Isaac Pitman and Sons, Ltd , 1930) 7s 6d net

(2) *A B C of Television, or Seeing by Radio a Complete and Comprehensive Treatise dealing with the Theory, Construction and Operation of Tele photographic and Television Transmitters and Receivers, written especially for Home Experimenters, Radio Fans and Students* By Raymond Francis Yates Pp viii + 210 + 13 plates (London Chapman and Hall, Ltd , 1929) 10s 6d net

(3) *Television Present Methods of Picture Transmission* By Dr H Horton Sheldon and Edgar Norman Grisewood Second printing Pp x + 194 (London The Library Press, Ltd , 1930) 10s 6d net

THESE three books together furnish a useful survey of television up to 1930 There have doubtless been subsequent developments It may be convenient to deal first with the work by S A Moseley and H J Barton Chapple This consists of a review of the work of J L Baird, who furnishes a foreword The other two volumes, which are of American origin, are of a more general character

(1) Mr Moseley and Mr Chapple deal with what is usually regarded as the real process of television, that is, the conveyance to a distance of a picture of something actually occurring at that instant, which may include moving objects The wireless transmission of drawings, photographs, signatures, etc , by a graphic process that is far from instantaneous is really a different problem, though naturally also of great scientific interest Mr Baird's foreword refers to the difficulties in securing facilities for broadcasting and the limitations imposed by the narrow waveband available, which at present leads to images being restricted to simple scenes He contends, however, that the number of pictures sent per second (about 12½ on his systems) need not be nearly so great as in cinematography

The "History of Television", which forms the first chapter to this work, makes references to the early pioneering work of Nipkow (1884), and to the transmission of silhouettes by Jenkins (1925) , but regards the demonstration by Mr Baird, described in NATURE of July 3, 1926, and quoted by the authors, as the first instance of the wireless transmission of real images In subsequent chapters the details of the apparatus are explained It is shown how the object is illuminated by intermittent light, the reflection of which excites changing currents in a photoelectric cell, how such currents are transmitted, magnified, and ultimately operate at the receiving end a neon lamp, which reacts instantaneously to each change in current, and how scanning discs at the transmitting end and carefully synchronised complementary discs at the receiving end serve to produce the illusion of an actual image The process, in this and other systems of television, is equivalent to selecting and conveying each element in a picture in turn, but with such rapidity that an apparently complete picture is presented The reproduced pictures, thus formed by a series of luminous lines, are certainly recognisable portraits The authors suggest that the equipment is relatively simple and within the scope of the amateur Efficient results, however, obviously demand technical skill, and perfect synchronisation at the transmitting and receiving ends demands great care

The concluding chapters are concerned with subsidiary recent developments, in themselves highly ingenious and interesting, but presumably requiring greater perfecting of the main process before they can be applied in practice We have, for example, 'phonovision', a process involving the reproduction on a gramophone record of rhythmical sounds, corresponding to the changes in the photoelectric current, which are thus stored, and can be released at any time in order to repeat a television image The authors also discuss the possibilities of colour and stereoscopic effects The former involves two scanning discs and two sources of light, one of neon gas furnishing red light, the other a combination of helium and mercury vapour, furnishing yellow, green, and blue Stereoscopic effects would require two identical but distinct sources and duplicate spirals on the scanning disc permitting 'double exploration' Of considerable interest also is the 'Noctovisor' apparatus, which consists essentially of a television transmitter and receiver coupled together but adapted to respond to infra red rays It is claimed that with such an apparatus a mariner could detect the presence of a distant source of light, even though completely shrouded by fog

(2) "The A B C of Television", by Mr R F Yates, is conceived on somewhat broader lines A chapter is devoted to "telegraphing pictures" Prior to this there is a review of existing television systems, which includes a useful explanatory diagram showing the details of transmitting and receiving ends The experiments made in the Bell Telephone Laboratories are described in detail, one

interesting feature being the use of a neon tube image-forming grid with no less than 2500 independent electrodes Other experiments mentioned are those of Max Dieckmann (based on the movement of cathode rays) in Germany and Belin and Holweck in France Subsequent chapters deal with photoelectric cells, amplification, the neon lamp, the problem of scanning, synchronisation, etc

(3) Dr Sheldon and Mr Grisewood, in their historical survey, deal mainly with the conveyance of pictures by telegraph and devote only a small space to television proper Subsequent chapters deal with optical systems and the eye, electro magnetic waves, selenium and photoelectric cells, glow-lamps and telephotography In Chapter xii and subsequent chapters, there is to be found what is perhaps the best review of various systems of television occurring in these volumes The Baird, Bell, Jenkins, and Alexanderson systems are dealt with successively

One cannot escape the feeling that the moving mechanism imposed by all these systems does not represent a final solution A final chapter points out, however, that the technical difficulties of television, great as they are, may be surpassed by those involved in a general process of broadcasting Had television arrived before the era of audible wireless, the use of the somewhat broad range of wave-lengths necessary for good reception would have presented little difficulty, to day, possible interference with the existing wireless broadcasting systems all over the world has to be considered

Universities of the British Empire

The Yearbook of the Universities of the Empire, 1931 Edited by Sir H Frank Heath Published for the Universities Bureau of the British Empire Pp xiii + 917 (London G Bell and Sons, Ltd, 1931) 15s net

THIS annual, first published in 1914, is primarily a conspectus of the staffs, organisation, and activities of universities, the numerous colleges connected with them, and a few other, unattached, colleges situated in various parts of the British Empire, as follows

	Universities	Unattached Colleges
England	11	4
Wales	1	
Scotland	4	
Ireland	3	
Canada	21	
Newfoundland		1
West Indies [1]		1
Australia	6	
New Zealand	1	
South Africa	5	
Mauritius [2]		1
Malta	1	
Palestine [3]	1	
India	18	
Ceylon [4]		2
Singapore [5]		2
Hong Kong	1	

[1] Imperial College of Tropical Agriculture Trinidad
[2] College of Agriculture
[3] Mandated Territory The Hebrew University, Jerusalem
[4] Medical College and University College, Colombo
[5] King Edward VII Medical College and Raffles College

From the calendar of each of these institutions have been selected such items of information as are likely to prove of interest to the members of other universities, schoolmasters, persons engaged in scientific researches, government departments, clubs, and the general public A directory of the officers and members of the staff of each university is followed by information as to its constitution, equipment, residential accommodation, courses of instruction, fees, scholarships open to graduates, extra mural work, publications, etc, and a summary of events of outstanding interest which occurred during the past academic year, with statistics of the number of students in attendance and degrees, diplomas, etc, conferred In the staff directories the names are grouped under subject headings and an additional indication is thus afforded of the scope of the instruction offered An alphabetical index at the end of the volume contains upwards of 12,000 names

In chapters introductory to the sections dealing with the universities of Great Britain and Ireland, of Canada, of Australia, of South Africa, and of India, respectively, are given summaries of information regarding their history, regulations, and practice, but not reviews of the academic year The Canadian chapter has been largely rewritten for this year's issue by Dr Stanley Mackenzie, of Dalhousie University, and now gives British readers a clearer idea of a series of developments of extraordinary interest The Canadian universities are kept in touch with one another by annual conferences, the fourteenth of which was held in May 1930 at Toronto, and by co operation with a National Council of Education which organises triennial conferences, the next of which will be in Toronto in 1932 The Australian universities, like the Canadian, hold conferences, which are arranged by a Standing Advisory Committee established in 1920 Similarly, in South Africa, since 1923, representatives of the universities and university colleges have met from time to time to discuss matters of common interest These universities,

moreover, have statutory powers to make joint regulations regarding matriculation, professional examinations, etc. The Indian universities set up in 1924 an Inter-University Board which meets annually: it has published a handbook of Indian universities. The question suggests itself whether it would not be worth while, with the help of these various co-ordinating organisations, to add to the introductory chapters annual reviews of the past academic year.

Appendices, extending to 170 pages, include summaries of the conditions governing admission, in Great Britain and Ireland, to the universities and to the medical and other professions and careers for which university studies are a fitting preparation, lists of open post-graduate scholarships, fellowships, etc., both British and foreign, and lists of centres of scientific research and information in the Empire, whether connected with universities or not, to which independent research workers are admitted. These lists have been greatly extended and rearranged and, of course, brought up to date. The aids open to British students in Great Britain and Ireland have now been arranged by grouping under subjects of study instead of under the names of the institutions offering the aid. This has not been done in the case of the Dominions and foreign countries, because the number available was too small. Anyone desiring to discover the relative amounts of provision of this kind made by universities, governments, scientific societies, or other bodies, can easily collect the information by using the general index.

The centres of scientific information in Great Britain are grouped under the four heads—botany and agriculture, industrial, pure science, and medical; the centres of research under these heads and forestry, fisheries and tides, and meteorology. The list of centres of research and information in the Dominions, India, and the Colonies is much fuller than before.

The extent and variety of the ground covered in the "Yearbook", especially the appendices, are such that the labour expended on it would be to a large extent wasted unless it were furnished with an adequate general index. This matter has evidently received the attention it deserves. In connexion with the indexing of the names of staff and officials, the treatment with any kind of uniformity of the Indian, Burmese, and other Oriental names presents extraordinary difficulties which the editor seems to have grappled with successfully.

Glancing through the summaries of events of the past year, one sees many significant items. Among the lists of benefactions one finds numerous gifts from American philanthropic foundations associated with the names Carnegie and Rockefeller. The beneficiaries include, naturally, many of the Canadian universities, eight of which participate in the benefits of the pension scheme of the Carnegie Foundation for the Advancement of Teaching, and the Universities of London, Cambridge, Durham (Armstrong College), Tasmania, Otago (New Zealand), and the Witwatersrand and University colleges at Exeter and Christchurch (N.Z.).

The 1931 "Yearbook" will have more than ordinary importance by reason of the fact that the fourth Congress of the Universities of the Empire is to be held this year, July 7–10, at Edinburgh. The previous congresses were held in 1912 (London), 1921 (Oxford), and 1926 (Cambridge).

Our Bookshelf

The Psychology of Clothes. By Dr. J. C. Flugel. (The International Psycho-Analytical Library, No. 18.) Pp. 257 + 17 plates. (London: The Hogarth Press, 1930.) 21s.

BOOKS which deal with dress from any but the historical point of view are only too few, and it is therefore refreshing to meet with a new one. Dr. Flugel's Psychology of Clothes should be read by everyone who takes an interest in modern garb, for it contains a wealth of facts and theories bearing on its origin, its effects, and its future.

To the widespread belief that clothes originated to enhance the attractiveness of the wearer, the author adds another, that they were intended to direct attention to the sexual organs. He further contends that garments may actually represent these, but his examples do not seem to be very convincing. To-day he finds the essential opposition between the motives of decoration and modesty to be the most fundamental fact in the whole psychology of clothing.

In the chapter on "Individual Differences", Dr. Flügel recognises a number of types, among them those who like to feel their skin uncovered and their muscles unhampered. Of these, some never get resigned to dress. Then there are unemotional individuals whose feelings fuse clothes and body into an harmonious whole.

One of the most striking matters touched upon under the heading of "Sex Differences" is the "great masculine renunciation", or sudden reduction in male decorativeness at the end of the eighteenth century, which it is claimed was connected with the French Revolution.

In discussing the "Why of Fashion", it is explained that the higher classes, when their sartorial distinctions are gradually appropriated by the lower, seeing that sumptuary laws seldom prove effective, adopt a different dress in order to re-establish their signs of superiority. In our days of levelling up, however, we are inclined to look for

commercial influences behind the scenes, which result in mistress and maid both wearing—shall we say?—'Russian boots'

Dr Flügel dwells in detail on other matters connected with fashion, and devotes a chapter to the "Evolution of Garments", a subject to which Sir George Darwin first directed attention

W M W

Principles of Soil Technology By Prof Paul Emerson Pp xv+402 (New York The Macmillan Co, 1930) 14s net

THE success in the arrangement and presentation of the subject matter in this book is the result of long teaching experience by the author This branch of agricultural science has progressed rapidly in recent years, and it is essential, therefore, that the establishment and development of the fundamental principles involved should be clearly understood by the student

The four sections of this book are (1) soil genesis, morphology, and classification, (2) soil physics, (3) soil chemistry, (4) soil biology In the first section the author stresses rightly the importance of studying the soil *in situ* Readers will appreciate the definitions and explanations that are given of the many less familiar terms used in soil classification and morphology, together with a description of the soil areas of the United States The presentation of soil physics to a student, without entailing the use of an advanced treatise on mathematics, is a difficult task The author has, however, succeeded, and conveys to the reader the essential principles and the results of recent work on soil structure air, and water movement, and their effects on plant growth Equally well treated is the section on soil chemistry, where the mechanism of base exchange is explained, as well as the source and utilisation of plant nutrients It should be pointed out, however, that a wrong impression of the salts of ortho phosphoric acid is given on p 242 All secondary and tertiary phosphates are not water insoluble, nor is the use of the descriptive terms, acid soluble and insoluble, for these, very fortunate Both forms, if we consider the case of calcium only, are soluble in dilute weak acids

Apart from this, the book is very well written It contains, in addition to the sections already mentioned, a very useful glossary of terms, numerous tables, graphs, diagrams, and maps of the United States

The excellent printing and binding make reading a pleasure, the price is low, and the references to the literature will be useful to post graduate workers

Elementary Biology for Matriculation and Allied Examinations By Mary E Phillips and Lucy E Cox Pp xiv+480 (London University of London Press, Ltd, 1931) 7s 6d

Now that biology has been introduced by all examination boards of England and Wales for the school certificate, as well as in many cases for the matriculation examinations, we may expect an outcrop of British text books in a field which hitherto has been largely in the hands of American authors The book under consideration is one of the first of the new series to enter the lists, and though primarily designed for matriculation examinations, its authors express the hope that it "may also prove useful in those schools in which biology is studied as a cultural subject" And why not? It is attractively written, well printed, and copiously illustrated No pains have been spared to render into assimilable form the subject matter, which is marshalled into five well balanced sections Thus (1) Simple living forms of increasing complexity, (2) external morphology and mode of life of some members of the chief classes of animals, (3) general morphology and physiology of the mammal (4) general morphology and physiology of the flowering plant, (5) the soil, bacteria, parasites and saprophytes, distinction and interrelation between plants and animals

With discrimination, the practical work is sifted from the text and collected at the end of each chapter The 282 illustrations cover a wide range of subjects, a very large proportion of them have an accuracy of finish which is not always associated with elementary text books There is no chapter on evolution, but the outlook of the authors is quite clear from their all too short "Introductory", while only the dullest reader could fail to be stimulated to think on evolutionary lines, by many remarks in the text

A Handbook of Physics Measurements By Ervin S Ferry, in collaboration with O W Silvey, G W Sherman, Jr, D C Duncan and R B Abbott Vol 2 *Vibratory Motion, Sound, Heat, Electricity and Magnetism* Third edition Pp xi+277 (New York John Wiley and Sons, Inc, London Chapman and Hall, Ltd, 1929) 12s 6d net

THIS book is devoted to measurements in vibratory motion, sound, heat, electricity and magnetism Practical details are preceded by a theoretical treatment which should enable the student to understand what he is doing The considerable space allocated to the theory of damped vibrations and the logarithmic decrement is welcome in view of their importance in relation to alternating currents, though in this connexion it is a pity that the theory of forced vibrations has not been included

A Junior Course of Practical Zoology By the late Dr A Milnes Marshall and the late Dr C Herbert Hurst Eleventh edition, revised by H G Newth Pp xliii+519 (London John Murray, 1930) 12s net

NOT many scientific text books first published in 1887 have still a demand in the laboratories of to day, at least in anything like their original form In preparing the eleventh edition, Mr Newth was probably well advised not to introduce physiology, which would, as he says, "have added greatly to its bulk, and the result could only have been a hybrid of very doubtful viability" In its present form, the book is likely to retain its position as the standard work on animal morphology for junior students

Letters to the Editor

[*The Editor does not hold himself responsible for opinions expressed by his correspondents Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE *No notice is taken of anonymous communications*]

The Action of a Crystal as a Two-Dimensional Lattice in Diffracting Electrons

KIKUCHI[1] first described examples of electron diffraction in which a crystal appeared to behave as a two dimensional or cross grating Very thin sheets of mica give an equilateral net like pattern of diffracted beams on the photographic plate (the N pattern), as if the only conditions for interference were those required by the lattice net of the mica cleavage plane Kikuchi further showed that, with increasing thickness of the mica, some spots are enhanced and others weakened until what he termed the L pattern is obtained The selection of the enhanced spots was accounted for satisfactorily by the operation of the third condition for interference, which depends on the regular repetition of the crystal structure in successive planes The L pattern, in other words, is explained by diffraction at a three dimensional lattice, in the manner familiar in the case of X rays

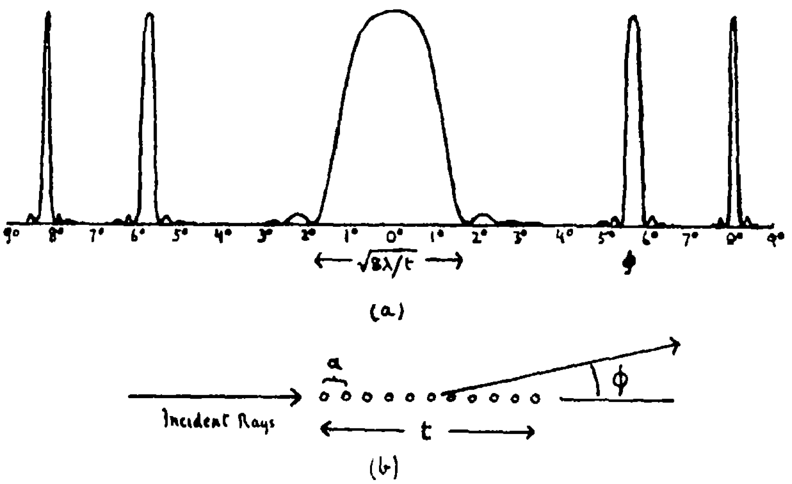

FIG 1

Linnik[2] obtained patterns somewhat like Kikuchi's N pattern, with copper K_α rays and mica which had been heated He suggested that they were due to a breaking up of the mica into sheets so thin that each acted as an independent two dimensional grating W L Bragg put forward an alternative explanation[3] that Linnik's effect was due to a slight distortion of the mica, which might be described as a random orientation of the normal to the cleavage plane over a small range It was suggested that a similar explanation might account for Kikuchi's N pattern

Certain experiments on electron diffraction by very small crystals made by one of us (F K) seem to show very clearly, however, the disappearance of the third condition for interference, namely, that depending on the repeat of the crystal pattern in the direction of the incident beam It is interesting to examine how thin a crystal must be for this condition to become inoperative

Let a row of n scattering points with spacing a be parallel to the incident rays, as in Fig 1 (b) The intensity of radiation scattered in a direction Q is proportional to $\sin^2 n\psi/\sin^2 \psi$ where $\psi = \pi a(1 - \cos\phi)/\lambda$. This curve is plotted in Fig 1 (a) for the case where $\lambda = 0\ 05$ A , $n = 10$, $a = 10$ A (thickness of crystal $t = na = 100$ A) Its interesting feature is the breadth of the central maximum, which is nearly 4° ($2\phi_0 = \sqrt{8\lambda/t}$) For all directions within this range, the whole row acts as a single diffracting unit and gives a strong resultant effect *

In actual cases of electron diffraction by a small crystal, the wave length is so short (0 05 A for 60,000 volts, as compared with 1 54 A for copper K_α) that many diffracted beams appear at angles well within this range The crystal in a fixed orientation can therefore give simultaneously a complete series of cross-spectra, for the crystal may be considered as a cross-grating of these rows, each of which acts as a single unit For example, in the case considered above, if the crystal also had spacings of 10 A at right angles to the beam, the cross spectra would be 17′ apart and more than one hundred would appear within the central maximum The difference between the patterns of X ray diffraction and electron diffraction is apparent, it is not merely one of angular scale For the row to act as a unit, it is necessary that $t(1 - \cos\phi) = t\phi^2/2 < \lambda$ When ϕ is small, $t\phi^2/2$ is a small quantity of the second order, and the condition is readily satisfied for directions of electron diffraction and crystals of the order of 100 A in thickness In the case of X rays, the 'cross grating' spectra fall outside the central maximum when the crystal is more than one or two atomic planes thick, and we have the familiar effect that only one diffracted beam is formed at a time, and that only appears when the crystal is correctly oriented

We may picture electron diffraction by a small crystal as follows Whenever the crystal is so oriented that a zone axis (row of scattering points) is approximately parallel to the incident beam, a complete cross-spectrum flashes out The cross grating is the projection of the crystal on a plane at right angles to the zone Such an orientation is a very special case More generally, when the crystal is so oriented that a set of planes is nearly parallel to the rays, the crystal acts as a *line grating* and forms several orders simultaneously on either side of the central beam

Both cases are shown in Fig 2 A powder photograph, taken with a coarse powder, has spots on the Debye Scherrer rings due to individual crystal grains These spots, in the case of electron diffraction, mostly occur in pairs symmetrically placed on either side of the central spot Each crystal grain is obviously diffracting spectra to both sides simultaneously The effect is very marked in powder photographs of sodium fluoride, where more than one order often appears on either side, but these photographs are difficult to reproduce here Fig 2 (b), which shows the same effect, is taken with crystalline matter in a collodion film, and the centro symmetry is very striking In Fig 2 (a), a single crystal chances to have a zone axis parallel to the beam, and the complete cross spectrum appears. These sheets were less than 100 A in thickness

We were privileged to hear recently a lecture by Dr Eisenhut in which slides of similar cross grating spectra produced by single crystals of cadmium iodide

* G P Thomson ("Wave Mechanics of Free Electrons", p 72) refers to the same feature in discussing the extent of the electron wave packet

and iron oxide (Fe_3O_4) were shown (O Eisenhut and E Knapp, I G Farbenindustrie Forschungs Laboratorium, Oppau)

This explanation is only partial, because the patterns are often more extended than any broad central diffraction maximum which is probable The central maximum can be seen in Kikuchi's photographs (for example, Fig 5, loc cit), but the corresponding mica thickness proves to be 200 A , which is much smaller than Kikuchi's estimate for the sheets he used In the single crystal photographs, the pattern is sometimes so extended as to indicate impossibly small crystal thicknesses It is interesting to note, however, that theoretically a small three dimensional crystal produces the effect of a two dimensional grating and gives a number of diffracted electron beams simultaneously Its dimensions at right angles to the beam can be sufficiently great to give a sharp cross grating spectrum, while an equal depth in the direction of the beam is insufficient to bring in the third condition for interference

The Velocity of Light

In a recent discourse broadcast by the B B C, reference was made to my communication in Nature of April 4 on the subject of the velocity of light Two objections were presented to the deduction that the velocity of light decreases, derived from the values quoted , these must have occurred to the readers of my letter, so that perhaps I may be allowed to refer to them briefly

(1) The possible errors do not rule out the possibility that the values are evaluations of a constant I stated this myself Physicists, however, are apt to overlook the fact that possible errors are no guide whatever in such a case as the one occupying our attention They are a mere mathematical guess as to the accuracy of any individual determination, and no more They leave entirely out of account the fact that observers, methods, apparatus, conditions, etc , may be different Of course, identical results from different observers have more weight than if the observers were the same person, and similarly for the methods, apparatus, etc For example, the value of a constant for which two different observers, working with entirely different techniques, have obtained results such as, say, 126 ± 50 and 128 ± 60 respectively is far more likely to be in the vicinity of either value, and therefore far better established, than if a single observer had obtained say, 102 ± 4 and 152 ± 6, using the same method and apparatus What is true of the constancy is also true of any law of variation

(2) In my letter, I have limited myself to determinations made in the present century This does not mean at all that I have rejected values obtained before which were acknowledged as being reliable Those who quote these earlier values without having made a thorough investigation, such as that which was published in Nature, Sept 17 and Oct 22, 1927, little realise how they allow themselves to be misled by a mere number alongside a name The value 299,853 obtained by Michelson in 1882, for example, has been mentioned as disproving a decrease of the velocity of light, when considered together with the four determinations I gave in my letter The fact is overlooked that this determination is one of three, made on relatively short bases, and therefore more liable to be affected by systematic errors of a given magnitude than the values obtained over very long bases or with a technique giving results of an equivalent order of physical accuracy, such as that of Karolus and Mittelstaedt, in which the high order of frequency of interruption of the luminous beam compensates for the shortness of the base These three values are

Michelson	1879 5	299,910 ± 50 km /sec
Newcomb	1882 7	299,860 ± 30 ,, ,,
Michelson	1882 8	299,853 ± 60 ,, ,,

They were obtained by two observers in close relationship, using the same method and the same experimental technique, with apparatuses which were similar , they constitute a set of their own, being the only observations made on such short bases (excluding the pioneer experiments of Foucault, which are admittedly mere attempts to ascertain the possibilities of the method) Now, each of these observations gives a result smaller than the one before ! The one before that of 1879 5 is Cornu Helmert's value, 299,990 ± 200 They, therefore, demonstrate a decrease of velocity, during the period which they cover , at any rate, their distribution along a perfect straight line, which, moreover, points exactly towards Cornu-Helmert's value, cannot be said to be accidental, any more than their agreement in giving a constant value, if they did so, could be said to be accidental !

I have treated the whole question at full length in a series of articles in *Ciel et Terre* (*Bulletin de la Société Belge d'Astronomie*, 1927–1931) In these, I establish the twenty two coincidences referred to in my letter There is not a single one against a decrease of velocity Can this be accidental?

Another point to be remembered is that the method of the revolving mirror, used by Michelson, is based on assumptions which, to my knowledge, have not yet been proved, namely, that the laws of oblique reflection on a moving reflecting surface, having a speed which is small compared to that of light, are the same as if the surface was at rest, and that the laws of

reflection of a pencil of light from a source, real or virtual, having a transverse speed of the same order as that of light, are the same as if the source was at rest

Deep-Focus Earthquakes

WITH reference to Mr. Scrase's letter in NATURE of Mar. 28, p. 486, a few additional remarks concerning deep focus earthquakes may be of interest. Such earthquakes are comparatively rare occurrences, and in the years 1918–1926 the late Prof. H. H. Turner reported only 138 in the "International Seismological Summary".

Turner's very great focal depths, amounting in one instance to 0·090 of the earth's radius below normal had to some extent fallen under suspicion, for three reasons:

(1) His depth of 0·040 for a normal earthquake shock is certainly faulty; the Montana earthquake of June 28, 1925, examined by Byerly, was not found by Turner to have an abnormally *high* focus, yet Jeffreys was able to show that the time distance curve agreed with that found for the Jersey and Hereford earthquakes of 1927, for which the foci were less than 20 km. deep, and he furthermore deduced from Byerly's curve a set of corrections to the Zoppritz-Turner tables that agreed with a set inferred by Turner from the residuals of a very large number of earthquakes.

(2) Turner's estimates of focal depth depended upon Knott's seismic rays which were in turn calculated from the Zoppritz-Turner tables; the known errors of these tables, particularly for small epicentral distances, require a revision of Turner's focal depths.

(3) The crucial test had not been applied to Turner's deep focus earthquakes that in view of a general reciprocal theorem in dynamics, the amplitude of a surface wave generated by a deep focus disturbance should be small if the amplitude of the disturbance of a wave of that type is relatively small at the depth in question (cf. H. Jeffreys, 'The Earth', 2nd edn., p. 136). Actually, the presence of *L* and *M* readings in the "International Seismological Summary" for many of the earthquakes of supposed very deep foci seems *prima facie* to constitute a valid objection to presuming foci of these depths.

As regards (1), it seems definite that Turner's value of the normal focal depth must be abandoned; (2) awaits the thorough testing of much improved tables, but a definite answer may be expected in the near future; (3) has recently been the subject of a detailed investigation, and the result which I am publishing in the forthcoming number of *Gerlands Beiträge* entirely supports the idea of abnormal focal depth, at any rate for the additional focal depths of 0·040 and more; a further investigation is being undertaken for depths of less than 0·040 below normal. The typical deep focus earthquake is most interesting; most of the energy is carried by body waves, and *P*, *PP*, *PPP*, *S*, *SS*, *SSS* are of very great amplitude; at the time where *L* and *M* normally appear there is a disturbance which is just the general motion corresponding to the dying down of the distortional waves. This weakening of the normal long wave phase is, of course, one of the distinctive features that Mr. Scrase refers to.

There is one partial exception to the previous statement. Although the normal *L* and *M* phases are practically absent from the shocks of very great depth, the phase known as *G*, Gutenberg's "Early Long Wave", of velocity about 4·4 km./sec., is often still discernible, although of rather small amplitude. It is to be expected that this wave of very long period should be sensible at much greater depths than the long waves of the normal *L* and *M* phases.

There is no difficulty in explaining the recorded *L* and *M* of the 'International Seismological Summary". A graph shows at once that they are sometimes *G*, but more often the large amplitudes of *S*, *SS*, *SSS*, so conspicuous in these deep focus shocks, are mistaken for surface waves.

It is greatly to be regretted that Prof. Turner, who carried out so many of the pioneer investigations of focal depths and to whose energy and enthusiasm their systematic study and report in the "International Seismological Summary" are due, has not lived to see the confirmation, both by the reciprocal theorem argument adduced by Dr. Jeffreys and by the important method discovered by Mr. Scrase, of the occurrence of abnormally deep foci.

Opacity and Stellar Structure

THE emission of the nuclear γ-rays from radioactive elements is accompanied by the photo-electrons emitted from the atom giving rise to the γ-radiation. This has been described by Ellis[1] as the internal photoelectric effect. For a long time, the obvious explanation has been that the γ-ray is sometimes absorbed by the extranuclear electron which is emitted with the energy given by the Einstein equation. Calculations based on this view, made recently by Casimir, lead to the conclusion that the probability of emission of the photoelectron is about 1/10 to 1/30 of that experimentally observed. Thus, for RaC γ-ray of energy 6.12×10^5 volts experiment shows that in 994 disintegrations out of 1000 the γ-ray escapes and in 6 it is absorbed. Therefore, the value for the probability of absorption is 6×10^{-3}, while the calculated value for this case is only 0.46×10^{-3}; that is, *the experiment shows the atom to possess about ten times more opacity for its γ-radiation than is indicated by calculation.*

The wave mechanics[2] does suggest, however, a different kind of energy transfer between the nucleus and the outer electron; that is, energy can pass directly from the nucleus to the electron without the intervening process of the emission of radiation in the nucleus and its absorption by the electron taking place. This may be called a radiationless energy transfer, and in fact the experimental results taken in conjunction with the calculations of Casimir indicate that such radiationless transfers are ten to thirty times more frequent than the radiational ones.

We now turn to the stellar structure.

The recent investigations of Prof. Milne[3] have led us to consider every star as made up of a degenerate core surrounded by a gaseous envelope. In the case of white dwarfs this gaseous envelope is negligible. The important question in connexion with the theories of stellar structure is that of opacity. The greatest difficulty of the theory of Eddington has been that it demands stellar opacities about ten times higher than can be allowed by physical considerations. It has been said[4] that Milne's theory only enhances this discrepancy.

The purpose of this note is to suggest that Milne's theory is capable, at least qualitatively, of overcoming this difficulty. In the degenerate core

because of the interaction between the electrons, there is a finite probability for the energy (and momentum) of an electron in one part of the core to pass directly to another electron in some other part of the core without the intervening process of radiation taking place; that is, in the degenerate core the transfer of energy mostly takes place by the radiationless process and this energy is then converted into radiation in the non-degenerate envelope surrounding the core. Because the energy is transferred by the radiationless process, the 'opacity' may be (as in the case of the radioactive atom) considerably higher than it would be if this transfer of energy took place in the form of radiation. *We may thus connect the discrepancy in stellar opacity to the same cause as that of the internal photoelectric effect in the atom.*

Another interesting point which may be mentioned is that of the emission of high speed electrons from the white dwarfs, which are almost completely degenerate, and hence the chances of collision for an escaping electron are very small. These high speed electrons *will in some cases have energies comparable to the cosmic radiation.* In fact, it can be easily seen that due to this electron escape a black dwarf will lose almost all of its mass—*the final state of a black dwarf is a diffuse mass.* These considerations will be published elsewhere in detail.

Coherent Expanded Aerogels and Jellies

THE continuity of the liquid permeating jellies is demonstrated by diffusion, syneresis, and ultrafiltration, and the fact that the liquid may be replaced by other liquids of very diverse character indicates clearly that the gel structure may be independent of the liquid in which it is bathed. Hitherto the attempt to remove the liquid by evaporation has resulted in shrinkage so great that the effect upon the structure may be profound.

Mr. Charles Learned and I, with the kindly assistance and advice of Prof. J. W. McBain, undertook to test the hypothesis that the liquid in a jelly can be replaced by a gas with little or no shrinkage. Our efforts have met with complete success.

The procedure that we have adopted is as follows. The jelly is first formed in a suitable liquid in dilute form. The liquid is then replaced by another which does not dissolve the structure and has a reasonably low critical temperature. Alcohol has proved quite satisfactory for most of the inorganic gels, ether has advantages in the case of easily reduced substances, and propane was used for all of the organic jellies. In making the replacement, it is necessary that each liquid used be completely miscible with both that which precedes and that which follows it. For example, water may be replaced by alcohol and then by ether. Mere evaporation would inevitably cause shrinkage. However, the jelly is placed in a closed autoclave with an excess of liquid and the temperature is raised above the critical temperature of the liquid, while the pressure is maintained at all times at or above the vapour pressure, so that no evaporation of liquid can occur and consequently no contraction of the gel can be brought about by capillary forces at its surface.

When the critical temperature is passed, the liquid has been converted directly into a permanent gas without discontinuity. The jelly has had no way of 'knowing' that the liquid within its meshes has become a gas. All that remains is to allow the gas to escape, and there is left behind a coherent aerogel of unchanged volume.

Silica aerogel with a density so low as 0.1 is very easy to prepare, and we have prepared some with a density of only 0.02. The silica aerogels are highly opalescent, although quite transparent; they display a glassy fracture and small pieces emit a metallic ring when dropped.

So far, we have prepared silica, alumina, nickel tartrate, stannic oxide, tungstic oxide, gelatine, agar, nitrocellulose, cellulose, and egg albumin aerogels and see no reason why this list may not be extended indefinitely. Apart from the scientific significance of these observations, the new physical properties developed in the materials are of unusual interest.

Two Modifications of Liquid Nitrobenzene

THE changes of dielectric constant and density of liquid nitrobenzene with temperature, studied by one of us (J. M.) and described in communications to NATURE, suggest that at 9.5° the liquid undergoes an energy transformation analogous to that found for liquid helium by M. Wolfke and W. H. Keesom,[1] and for liquid ethyl ether by M. Wolfke and J. Mazur.[2]

To confirm this supposition we have made a study of the heating curve of carefully chemically purified nitrobenzene. Nitrobenzene cooled to a temperature lower than the point in question (6° C.) was contained in a Dewar vessel provided with a nickel-plated

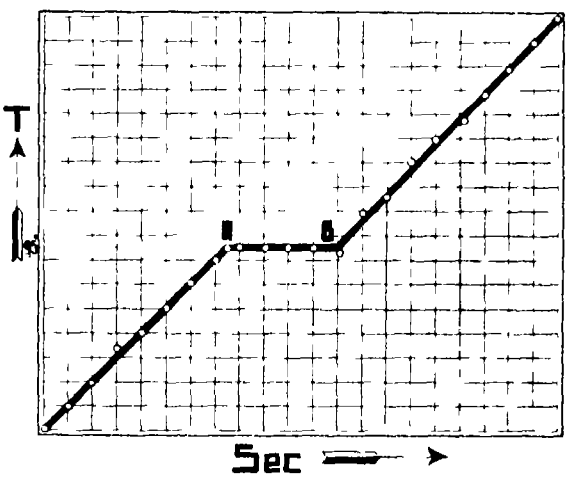

FIG. 1.

refrigerator. We have studied the change with time on gradually increasing the temperature of nitrobenzene which was isolated from all external disturbances.

The platinum resistance thermometer, calibrated with the aid of the standard thermometer of the Cryogenic Laboratory at Leyden, was used as a stirrer.

The experiments were repeated three times and they show that at 9.5° there is a distinct slowing down of the rate of change of temperature (see the part *A B* of the curve, Fig. 1). The parts of the curve above and below the point 9.5° are parallel straight lines, which

shows that the specific heat of nitrobenzene does not undergo a change at 9 5°

This phenomenon is a third case of appearance of a transformation point for two different modifications of a liquid

Adsorption of Hydrogen on Charcoal

IN connexion with the recent development of the theory of activation of adsorption processes by H S Taylor (J A C S, 53, 578, 1931), it may be interesting to note that a 'Norite charcoal, which adsorbed practically no hydrogen at room temperatures, adsorbs hydrogen at increasing rates as the temperature is raised Thus, when 1 17 c c hydrogen were admitted to the charcoal at 395° C, the pressure fell from 0 514 cm to 0 076 cm after 9 hours, about 1 c c of gas being adsorbed At 340° C, with an admission of 1 19 c c, the pressure only fell from 0 572 cm to 0 251 cm in a similar period, showing a much smaller and slower adsorption of hydrogen than at 395° C At temperatures below 200° C the rate of adsorption is too slow to be measurable

The Wall of the Cotton Hair

MEASUREMENTS of the dimensions of cross sections of cotton hairs have been obtained by us at Giza, in some preliminary studies for technological purposes, of different pure lines of Egyptian cotton On plotting correlation diagrams between the thickness of the cell wall and the 'ribbon width' (the maximum diameter of the collapsed cell tube) we have detected several facts which are of exceptional interest to plant physiology as well as to technology A characteristic diagram is here reproduced (Fig 1)

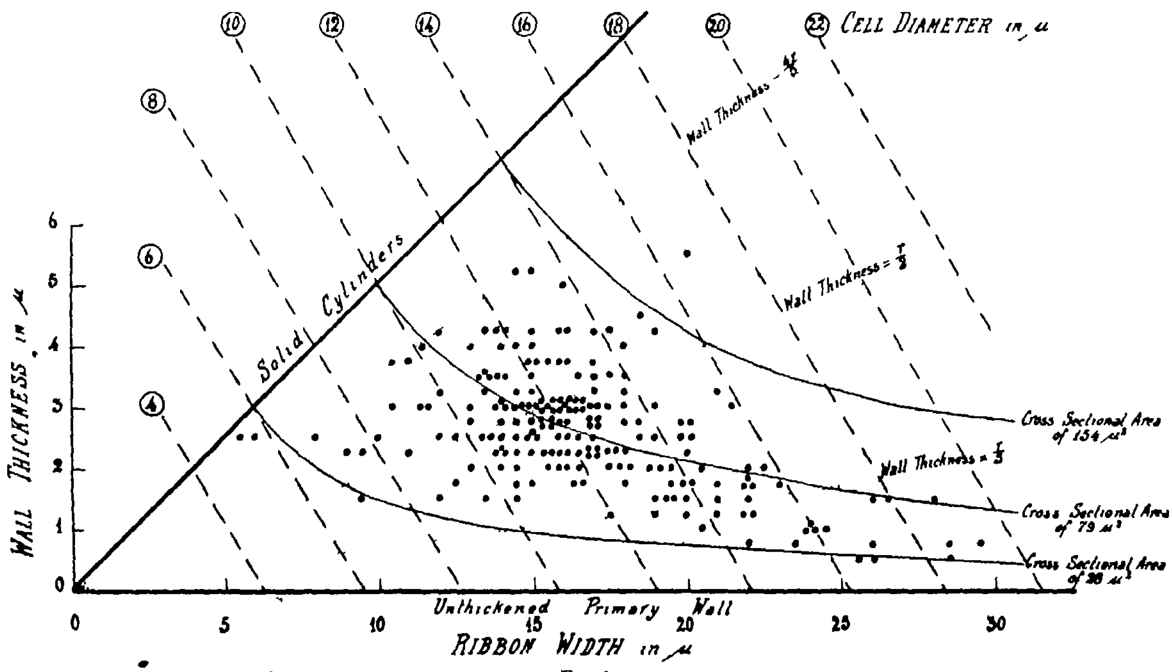

FIG 1

The nomograph lines drawn on this diagram are self explanatory, excepting perhaps those of equal cell diameter, which are the result of the fact that a fully thickened hair cannot collapse at all, so that its ribbon width is identical with the cell diameter, contrariwise, a very thin walled hair collapsed until its ribbon width is almost equal to half the circumference of the cell [1] Strictly speaking, these lines should not be straight, also there are small sources of error in measuring the ribbon width of very thin walled hairs, but we can disregard these minutiæ for the present purpose

The outstanding feature is that the correlation axis tends to follow the curved lines of equal cross sectional area Otherwise stated, the volume of cellulose forming material which enters each cell would be approximately constant if the cells were of equal length A strong cross checking observation has been formerly recorded by one of us [2] in the fact that variations of wall thickness during the whole fruiting season are not of linear dimensions, although the quantity measured is a linear one, but they are definitely of square dimensions, that is, areas This result is, however, not simply a matter of volume of cellulose, because the hair weight per centimetre is known to be nearly constant for all lengths of hair,[3] so that we cannot describe the wall thickness as being conditioned by the area of primary wall surface which has to be covered in spite of the fact that it is so conditioned by the perimeter of the tube This curious discrepancy may help to illuminate the mechanism of cellulose deposition [4]

Actually the diagram shows that in the cells of larger diameter the wall is even rather thinner than a strict adherence to constant area would suggest, the curvilinear correlation axis (not drawn) crosses the 79 μ^2 line

A problem of the cell wall as yet unsolved is whether thin walls have the normal number of growth-rings, or whether they are thin because only a few growth-rings have been deposited The form of the lower boundary of the group of dots (bounded as it is by the 28 μ^2 line) strongly suggests that every one of

the two hundred cells measured has undergone the full sequence of growth-ring deposition, otherwise there should be thin walls among the small diameter hairs

The form of the upper boundary, showing that a lumen the radius of which is about one fifth of the cell radius is normally left unfilled, is of physical interest, as will be seen presently

A result of technological importance, both to cotton spinner and cotton grower, relates to the question of 'nep' These hairs (which have walls so thin that they easily roll up into tangled bundles during their passage through the machines) are seen in this diagram to be predominant in the cells of big diameter, and to be absent among small diameter cells Formerly one had imagined that they would be found in all diameters

Lastly, we would point out that care should be taken in translating such data as these, drawn from the dead dry hair, into terms of growth and development We have found that the frequency diagram of cell diameter undergoes remarkable modifications according to the condition of the hairs when measured Living hairs measured from the green boll are much larger than the dead hairs, and these again are much larger than hairs 'swollen' with caustic soda to restore them to cylindricality, in Harland's method [5] But, whereas the shape of the frequency distribution is unchanged between the living hair and the soda treated hairs, the case is quite otherwise with the dry dead hairs, these have a far more compact distribution, and we have verified by direct search through our material that the thick walled small hairs actually enlarge their diameter when the irreversible loss of water takes place at death, their centre is in compression when alive, presumably through convergence of the space lattice columns of the fibrils towards the centre This inference is cross checked by Slater's unpublished observation, that the core of a cylindrical hair is more rigid than its periphery In the thin walled hairs, the removal of the water lost irreversibly after death allows the periphery to contract, the outer growth rings, primary wall, and cuticle are thus in a state of tension, which accounts for the fact that most cross sections of the dead cell have a crumpled appearance, unless the wall is more than half a radius in thickness On softening with caustic soda, this tension relieves itself and the diameter decreases still further, even in the thick walled small hairs

It is remarkable that the physical properties of the cellulose wall should result in presenting to the cotton spinner a much more uniform product than is produced on the plant, even though the plant has already done its best for him by making hairs of fairly uniform weight out of cells the diameter of which varies greatly Thus, in the present diagram, the range of cell diameter from 5 to 19 microns (μ) might be expected to entail a range of cross sectional area from 25 to 361 (being the squares of these diameters), whereas the actual area range is only from 25 μ^2 to 220 μ^2

Plankton Changes on the Coast of Ecuador.

I HOPE some oceanographer will be prompted to write at length some explanation (1) of the erratic behaviour of El Niño and (2) of the lenses of foul yellow water of which Mr G Sheppard writes in NATURE of April 25 May I make two suggestions ?

The coolness and fertility of the Humboldt water is due to the upwelling of water from the depths to replace surface water blown westward by the prevailing off shore winds of Peru and Chile In *Yachting* of March and April, I read that the sailing yacht *Carlsark*, in six weeks of a voyage across the Atlantic last year, in the trade wind belt had only one day of north east trades—and that, the first day out of Santa Cruz Might not the cause of El Niño overcoming the Humboldt be due to a similar failure of the south east trades over the Andes ?

Winter gales pile up sea wrack in the salens of Scotland's west coast Several such inlets have the appropriate place name of Brennfort (stinking port) With an off shore wind and a high spring tide, I have seen huge areas of this putrid weed carried out into the sound in summer time May I suggest, though unfamiliar with local physiography, that the prevailing in shore wind of the Bay of Panama chokes up lagoons with rotting sea ware, and that, concurrently with high tides, a reversal of the usual wind, for example, by the north east trades crossing the Isthmus, might carry out the stagnant water to join El Niño ?

I fear this is not a sufficient cause for the vast volume of putrid water that created such havoc among fish and birds off the Peruvian coast some six years ago I have heard that boats painted with white lead turned quite black That extensive miasma might have been due to volcanic action in the seas round the Galápagos

WILLIAM SEMPLE

April 27

MR G SHEPPARD's letter under this heading, in NATURE of April 25, directs attention to a matter which may be of serious importance Apparently, the fœtid plankton accumulations described were dead material Years ago, when oil began to be discharged upon the troubled waters of the oceans, some of us suggested *that the plankton might suffer* Since then, multitudes of birds have been cast dead upon our shores enwrapped in oil Occurring as these discoloured patches do, in the steamship lanes, they may be but a fulfilment of our prediction—one which sooner or later must come true we cannot for ever sin against Nature Has any attention been paid to such possibility by those who are studying the problem ? Forced by modern sanitary practice to send our phosphates to sea, it will be strange if revenge be taken, through the oil wasters who are everywhere fouling the ways of life through their interference with the recovery of phosphate by plankton

The Mode of Action of Insulin

IN a consideration of the mode of action of insulin it is of some importance to know the equivalent relationship between the amounts of hormone and dextrose, that is, the number of molecules of dextrose equivalent to one molecule of insulin Up to a recent date this ratio was not known, on account of lack of knowledge of the molecular weight of insulin A recent communication to NATURE [1] from Prof The Svedberg has, however, provided the necessary information on this point The molecular weight of 35,100 deduced

by Prof Svedberg is in agreement with the physico chemical behaviour of insulin, and is of the same order as those of ovalbumin and Bence Jones protein

According to the extensive determinations of Culhane Marks, Scott, and Trevan,[2] one international unit of insulin is equivalent to 1/24 mgm of crystalline insulin The weight of dextrose which this amount of insulin will remove from the blood is provided by data from the standardisation of insulin by the fall of blood sugar in the rabbit Assuming that the blood of a rabbit averages 1/13 of the total weight the mean of the blood sugar decrease in 174 rabbits (starved for 24 hr), following injection of one unit of insulin, amounts to 100 mgm of dextrose In order to obtain this figure (for which I am indebted to the Pharmacological Department of these laboratories) the maximum drop of blood sugar level has been taken The true figure is probably higher, for although the decreased blood sugar level inhibits the physiological production of insulin, the resulting liver glycogenolysis would tend to prevent the minimum level being attained This glycogenolysis is subnormal in rabbits starved for 24 hours

The only other figure available in the literature is that due to Bouckaert *et al*,[3] who found that in order to maintain a normal blood sugar level in rabbits receiving parenterally 1 26 gm of dextrose per kgm per hour, the injection of 6 8 units of insulin per kgm per hour was necessary This indicates that one unit of insulin is equivalent to 185 mgm of dextrose I have taken a mean value of 150 mgm as the dextrose equivalent of one international unit of insulin Hence it follows that 1 gm of insulin will remove 3600 gm of dextrose, or using the value of 35,100 for the molecular weight of insulin, one molecule will remove $\frac{3600 \quad 35100}{180}$, or approximately seven hundred thousand molecules of dextrose Thus, there is no possibility that the action of insulin in removing dextrose from the organism is a stoichiometrical one depending on the presence of a number of certain active groups in the insulin molecule F O HOWITT

Singlets of the Two-Electron Spectra B II, C III, N IV, and O V

IN a recent analysis of C III the absolute term values of singlets and triplets could be independently determined from the D series in both systems The difference $2\ ^1S_0 - 2\ ^3P_1$ was obtained as 52 380 ± 200 cm^{-1}, which conclusively proves that λ2297, ν43524 cannot be the intercombination line, proposed by Bowen and Millikan [1] Indeed, no such line has been found, in agreement with the improbability of a change of s in a spectrum with such small j separations

The strong C III lines λ2297 and 1247 are identified with transitions to the normal $2s\ 2p\ ^1P_1$ from the two deep terms $^1D_2$ and $^1S_0$, arising from the configuration $2p\ 2p$ The terms thus obtained are checked by a large number of combinations with higher singlet levels

In consequence of these identifications, the corresponding transitions in B II are taken as the lines λ3452 and 1842, previously thought [1] to be $2\ ^1S_0 - 2\ ^3P_1$ and $2\ ^1P_1 \quad 3\ ^1S_0$ Using the irregular doublet law, the combinations $2S - 2P$, $2P - 2D'$, and $2P - 2S'$ are then found for N IV and O V as shown in the accompanying tables Three of the tabulated lines, B II $2P - 3D$, B II $2S - 2P$, and C III $2S - 2P$, were given their right assignment by Bowen and Millikan [1] The terms are calculated from $2P - 3D$ on the assumption that

$$3D - Z^2 \times \frac{109{,}737}{3^2}\frac{1}{\ },$$

which was very closely verified for C III by 5 members of the D series The n^* for D' and S' are referred to the $2p$ state of C IV

	$2P \quad 3D$	$2s\ 2p\ ^1P_1$	$2S - 2P$	$2s\ 2s\ ^1S_0$
B II	72,519 1378	121,291 1 90	73,396 1362	194,687 1 50
C III	174,131 574	283,868 1 86	102,351 977	386 219 1 60
N IV	298 525 335	493,613 1 89	130,687 765	624,300 1 68
O V	453,819 220	758,644 1 90	158,795 629	917,439 1 73

	$2P - 2D$	$2p\ 2p\ ^1D_2$	$2P - 2S$	$2p\ 2p\ ^1S_0$
B II	28 966 3452	92 325 1 77	54 264 1842	67,027 1 95
C III	43 524 2297	240 344 1 80	80 168 1247	203 700 1 92
N IV	58 189 1724	435 424 1 85	104 676 955	388,937 1 93
O V	72 924 1371	685 720 1 87	129 112 774	629 532 1 94

In the next table, $3P$ is determined from $2S \quad 3P$, and then, confirming the term system strong lines are found in all the spectra at exactly the calculated position for $2D - 3P$ In C III, $2S' - 3P$ was also found

	$2S - 3P$	$2s\ 3p\ ^1P_1$	$2D - 3P$ calc	$2D - 3P$ obs
B II	144,105 693	50 582 2 95	41 743	41 740 2395
C III	258 941 386	127,278 2 79	113 056	113,056 884
N IV	404 524 247	219,776 2 83	215 648	215,652 463
O V	580,828 172	336,611 2 86	349,149	349,113 286

These transitions, $2p\ 2p\ ^1D_2 - 2s\ 3p\ ^1P_1$ and $2p\ 2p\ ^1S_0 - 2s\ 3p\ ^1P_1$, are in accord with the Heisenberg selection rule [2] for two electron jumps, $\Delta l_1 = \pm 1$, $\Delta l_2 = 0$ or $+2$ However, no trace has been found of the corresponding transition in the triplet system, $2p\ 2p\ ^3P - 2s\ 3p\ ^3P$, agreeing with another form, $\Delta l_1 = \pm 1$, $\Delta l_2 = \pm 2$, given as the Heisenberg rule by Grotrian [3] and Pauling and Goudsmit [4] It seems as if the observed data in C III could be represented by the addition to the selection rule that the transitions $\Delta l_1 = \pm 1$, $\Delta l_2 = 0$ are allowed only if $\Delta L = \pm 1$

Modern Progress in Vertebrate Palæontology *

By Sir ARTHUR SMITH WOODWARD, F R S

IN a paper read to the Zoological Society in 1880, Huxley remarked that the astronomer who had determined three places of a new planet could calculate its place at any epoch, however remote, and if the law of evolution was to be depended upon, the zoologist who knew a certain length of the course of that evolution in any given case, might with equal justice reason backwards to the earlier but unknown stages He accordingly surveyed the back-boned or vertebrate animals both living and extinct, so far as they had then been discovered, and he defined the successive stages through which they must have passed before they ended in the higher warm blooded quadrupeds and birds which dominate the world of life to day He pointed out how, in the existing world, most of the earlier stages are represented only by animals with very special adaptations to their several modes of life, which give little idea of the variety displayed by animals of the same stage in former geological periods He concluded that a multitude of extinct groups of each stage had still to be revealed, most of those groups being short lived adaptations to the several spheres of life which were open to them at the time, and only a small proportion on the direct line of ancestry of the existing vertebrate animals The actual links in the chain of life from the lowest to the highest rank must, therefore, have been comparatively few

Even in Huxley's time there were already indications of several more extinct groups than those he dealt with in his researches, but the fossils by which they were known were too fragmentary to be satisfactorily interpreted During more recent years, those early discoveries have been supplemented by numerous collections from various parts of the world, while the methods of preparing and studying even the most unpromising fossils have in all respects greatly improved Much progress has, therefore, been made in understanding the relationships of the extinct forms of life, and in using them for discussing the problems of organic evolution The vertebrates, especially, have proved remarkably interesting

The earliest forerunners of the vertebrate animals (the Hypichthyes of Huxley) have not yet been found among fossils, probably because they had no hard parts capable of being preserved in ordinary circumstances in rock They are still known only by their highly modified living representative, *Amphioxus* Huxley's second stage, however, that of the Myzichthyes, represented by the lampreys and hag-fishes at the present day, has now been identified among fossils exactly where it might have been expected It flourished especially in the latter part of the Silurian period, but ranged from the Ordovician to the Devonian It included free-swimmers like the Anaspida, which have been found well preserved in the Upper Silurian (Downtonian) rocks of southern Norway and southern Scotland They had an external skeleton enough to show that, while they agreed with the lampreys in the single narial opening and in the pouched gills, they had less degenerate jaws and possessed incipient paired pectoral fins They also resembled the larva of the existing lamprey in having the end of the body turned downwards into the tail fin They were accompanied by other Myzichthyes, like the Cephalaspidians, which were bottom dwellers and had both an external skeleton and an internal head skeleton so well ossified that in specimens discovered in Spitsbergen, Prof Erik A Stensio, of Stockholm, has been able to recognise many of their lamprey like characters The surviving lampreys and hag-fishes, therefore, give no idea of the variety and adaptations of the Myzichthyes in their prime, when they dominated the world of life

The next stage, that of the Chondrichthyes, represented by the existing sharks, skates, and chimæroids, has also lately been recognised as dominant in its proper place in the geological record Thanks especially to the researches of Stensio, it now seems clear that during the latest part of the Silurian period and the Devonian period, when these fishes were in the forefront of progress, they developed true bone both externally and internally They included the free swimming Acanthodians, which are very shark like, but have long been puzzling because, although their skeleton does not consist of typical bone, it is of more complex structure than the hard tissue of any modern shark or skate The Chondrichthyes also included the heavily armoured grovelling fishes like *Coccosteus* and *Dinichthys*, which are now generally known as *Arthrodira* Quite lately, Prof F Broili has described a skate-shaped fish, *Gemuendina*, from the Lower Devonian of Germany, which seems to combine the characters of an Arthrodiran with those of a skate Also, not long ago, Prof P Pruvost found, in the Lower Carboniferous of Belgium, part of a peculiar shark, *Cratoselache*, which retains the remnants of the bones of an Arthrodiran in the roof of its skull

Huxley's next stage in the evolution of the vertebrates, that of the Herpetichthyes, or fishes which gave rise to the lung-breathers as well as to the typical modern fishes, proves to be represented among fossils not precisely as he supposed it to be The Dipnoi, which he thought were the ancestral lung breathers, seem now to be merely an offshoot which ended in the existing *Lepidosiren*, *Protopterus*, and *Ceratodus* The real links between the Herpetichthyes and the earliest lung-breathers or Amphibia are the osteolepid fishes, which begin just where they might be expected, in the Middle Devonian rocks

The Amphibian stage occupied the foremost place in the world of life of the Carboniferous period, and

* From the Huxley Lecture delivered in the Imperial College of Science on May 4

Prof D M S Watson has shown that some of its representatives during this period, the early stegocephalians, are remarkable links between the osteolepid fishes and the later amphibians

The next or Hypotherian stage, which flourished in the Permian and Triassic periods, included the ancestors of the mammals besides those of the reptiles and birds Huxley did not recognise the former, but since 1880 the discoveries of Seeley, Watson, Haughton, and especially Broom, in South Africa, have revealed skeletons of cynodonts which can scarcely be distinguished from those of primitive mammals In general appearance the skull always resembles that of a carnivorous mammal, and the teeth are arranged as if they were incisors, canines, premolars, and molars The teeth also differ from those of ordinary reptiles in having scarcely any replacing teeth Still more remarkable is the lower jaw, which consists almost entirely of the pair of dentary bones, as in a mammal, the other bones being reduced to a little cluster behind where they articulate in the reptilian way with the quadrate bone of the skull In some of the little cynodonts which are no larger than rats (Ictidosauria), the quadrate bone is so small that it forms only part of the articulation for the lower jaw, the rest being formed by the squamosal bone, which extends to the whole of it in mammals Through the cotylosaurian reptiles there are indications of every gradation between these cynodonts and the earlier amphibians, so that satisfactory links between the lowest and the highest land vertebrates will probably soon be forthcoming

It is especially interesting to note that the nearest approach of the hypotherian stage to the next higher or prototherian stage is made by species of comparatively small size, for when undoubted Prototheria first appear later in the Jurassic rocks, scarcely any of them are larger than rats When the first known representatives of the next higher mammalian stages of Metatheria and Eutheria follow them in the Upper Cretaceous rocks, the species are of equally small size So far as palæontologists have experience at present, all links between the greater groups of vertebrate animals are to be found among the smallest, not the largest species

Owing to the fragmentary nature of the fossils, little can be said about the Prototheria, which are represented in the existing world only by the monotremes of the Australian region During the Jurassic and Cretaceous periods, they were overshadowed by the reptiles which flourished everywhere, and they seem always to have occupied a subordinate position Very little is known also of the earliest Metatheria and Eutheria, which are represented at the present day by the marsupials and the higher (placental) mammals respectively They appear together in the Upper Cretaceous formations of western North America, and skulls of small Eutherians have lately been found by an American expedition in corresponding rocks in Mongolia. It is clear, however, that by the beginning of the succeeding Tertiary period, which has well been named 'The Age of Mammals', the chief groups of Eutherians were already diverging into the several lines which have eventually become more clearly separated and even again subdivided In certain paragraphs of his classic paper of 1880, Huxley distinctly recognised these facts and briefly stated them It is, therefore, curious that he used parallel lines instead of diverging lines to represent the hypothetical pedigrees in his "Table of the Arrangement of the Mammalia", which has accordingly been criticised with some justification

Huxley's interest in the subject was first roused by the numerous discoveries of ancestral mammals which were being made in the 'seventies in the Tertiary land deposits of western America, and especially by his visit to Prof O C Marsh in 1876, when he examined the great collection of fossils in the Museum of Yale University at New Haven At this time, Prof Marsh had just arranged a series of specimens to show the genealogy of the horses, beginning with little four toed swamp animals which had low intelligence and crushing teeth, and ending in the largest one toed, plain roaming animals, which had a much superior brain and grinding teeth Subsequent more elaborate collecting and research in the same rocks by Prof H F Osborn and his colleagues, of New York, have shown that the gradual evolution of the horses can sometimes be followed even in the most minute characters At the same time, they have proved that the tracing of genealogies among the fossil mammals is not so easy as was at first supposed, even when the specimens are numerous and display well-preserved important features It now appears that in each group there is no single line of advance, but there are several lines all changing in the same direction, only with slight differences and often at different rates These are generally assemblages adapted for somewhat different modes of life Such parallel developments have been observed in America among the fossil rhinoceroses, camels, cats, and other groups, and they are especially evident in the extinct hoofed animals known as the Titanotheres, which have lately been described by Prof H F Osborn in the most exhaustive treatise ever devoted to a group of fossil vertebrates There can, indeed, no longer be any doubt that each great group starts its career in geological time with certain innate potentialities which we do not understand, but which compel all its members, however varied may be their respective adaptations and modes of life, to follow the same course to the end

In the Old World, we have had fewer opportunities of following the evolution of the Eutherian mammals, because the fossil record has so far proved much more incomplete Among achievements during this century, however, must be specially mentioned the discovery by the late Dr Charles W Andrews of the pedigree of the elephants Even in this case, we now realise that some remarkable changes occurred independently in more than one line Among the later elephants, at any rate, there must have been several parallel series evolving in the same direction

The Old World, nevertheless, has its compensations, for here we are able to study the most fascinat

ing problem of all among mammals, the ancestry of man himself There can now be no doubt that the man-like apes have always been restricted to the Old World, and that the ancestors of man must be sought among their ancestors Hitherto, we have not made much progress, but the few discoveries that have rewarded our efforts during the present century are decidedly encouraging In Huxley's time, the only fossil man known which exhibited more resemblances to the ape than any existing man, was that of the race first met with in 1856 in a cave in the Neanderthal, near Düsseldorf, Germany His skull resembled that of the apes in its great bony brow-ridges, and his lower jaw lacked the usual prominence at the bottom of the bony chin Among subsequent discoveries, the fragment of skull of *Pithecanthropus* from Java has still more prominent brow-ridges, and a human lower jaw from Heidelberg has a still more ape like bony chin On the other hand, the equally ancient skull of *Eoanthropus* from Piltdown, Sussex, has a good forehead without brow ridges, and it approaches apes chiefly in its remarkable lower jaw and teeth Now we welcome the recent discoveries of skulls and teeth of another fossil man, *Sinanthropus*, which have been made in a cave not far from Peking, in China These fossils date back to a geological period at least as remote as those of *Pithecanthropus*, *Eoanthropus*, and the Heidelberg man, and it is not impossible that they are more ancient They are, therefore, of extreme interest, and Dr Davidson Black's preliminary descriptions and beautiful photographs of them show that they are specially important as displaying in combination several characters which in previous specimens have been separate and distinctive In top view, for example, the skull of *Sinanthropus* looks astonishingly like that of *Pithecanthropus*, with the same bony brow-ridges, but the frontal region and parietal bosses are more tumid, and the bone is much thicker The brain-case is as thick as that of *Eoanthropus*, and the bone has the remarkably fine spongy texture which has previously been observed only in the Piltdown fossil The skull of *Sinanthropus* is also low and squat, with the same broad base and peculiarly-shaped occiput as in *Eoanthropus* It also has the modern-looking deep sockets for the articulation of the lower jaw The lower jaw and teeth of *Sinanthropus*, however, are more like those of Heidelberg man This combination is indeed curious, and each new discovery makes it more clear that modern man is the sole and successful survivor of many and very varied former approaches to the unique position which he now holds

In conclusion, the question arises as to whether such modern advances as have been described here, in the study of fossil vertebrate animals, are definitely leading to a better understanding of the general principles of our science We may reply that the progress already achieved has, indeed, been helpful in this respect, and that it is now much easier to predict lineages and the course of discovery than it was in 1880, when Huxley ventured on his pioneer essay We have made distinct progress in correlating changes in the world of life with alterations in surrounding conditions, and we can often trace gradual improvement in adaptation to controlling circumstances

It seems possible to recognise now even that the few fundamental advances in the evolution of the vertebrates have all coincided with widely spread "revolutions of the globe", to adopt Cuvier's old expression, which we may now use in a new sense The passage of the Myzichthyes into the Chondrichthyes seems to have occurred when fishes first ventured from the shallows into the open ocean The Herpetichthyes probably began in adaptation to the conditions of the fresh-water lakes, in the deposits of which we first find them During the Devonian period, when this adaptation was complete, the rocks show that there was widely spread desiccation in many parts of the world Conditions were, therefore, favourable for the origin of the amphibia, which seem to have appeared at about this time In the Permo-Triassic period there were again most extensive deserts, and the speculation has been hazarded that the reptiles, which had then become established, were stimulated to activity and evolution by the need for long journeys in search of food Some of the earliest reptiles, or Hypotheria, passed into the Prototherian mammals when genial conditions were advancing The Metatherian and Eutherian mammals first began to spread and take the place of the vanished dominant reptiles at the end of the Cretaceous period, when there were world disturbances in mountain building and a cooling of the climate in large areas of the northern hemisphere Finally, man emerged from the ape grade probably in the northern hemisphere during the hard circumstances at the beginning of the Great Ice Age in the Pleistocene period

Direct competition between the representatives of one stage and the next seems rarely to have happened The giant land reptiles, for example, which dominated the world during the Jurassic and Cretaceous periods, can scarcely have been exterminated by the competition of the mammals, which were all very small and scarcely came in contact with them The mammals spread and flourished only when the lands had become practically vacant, and long after the reptiles had disappeared, even so late as the Lower Eocene period, there were still no land animals of any kind larger than a pig Similarly, the great sea reptiles which lived until the end of the Cretaceous period, were not exterminated by the whales which eventually took their place We now know that the whales originated only after the ichthyosaurs, plesiosaurs, and mosasaurs had vanished, and that even the comparatively small ancestors of the whales never entered into competition with these forerunners in their sphere in the oceans

It is, indeed, probable that the procession of life which we observe has depended as much on the influence of surrounding conditions as on the inherent characters and tendencies of the various groups of organisms themselves For a further understanding of the subject, therefore, geologists and biologists must still continue to co-operate

Engineering Research in Great Britain

JAMES FORREST, who died on March 2, 1917, at the age of ninety one years, was connected with the Institution of Civil Engineers for fifty-four years, during forty of which he was assistant secretary or secretary It was the ambition of his life to make the Institution the premier professional society in the world, and during his tenure of the secretaryship the names on the roll of the Institution rose from between 800 and 900 to 6900, and the annual income from £3000 to £20,000 He retired from office in 1896, but six years previously the Council, to mark its appreciation of his work, presented his portrait to the Institution, and a little later the members placed at his disposal a sum of £500 Forrest himself determined that this should be devoted to the establishment of a James Forrest lectureship, to be administered by the governing body of the Institution and in 1893, Sir William Anderson was chosen to deliver the first lecture in accordance with the trust

Anderson's lecture was on the Interdependence of Abstract Science and Engineering ' Another lecture, given in 1896, was by Sir Alexander Kennedy, whose subject was ' Physical Experiment in Relation to Engineering

While these subjects gave a wide field over which the lecturer could roam at will, other lectures have been devoted to some specific branch of engineering, as, for example, the lecture on ' Unsolved Problems in Metallurgy ', delivered by Sir Robert Hadfield in 1906, and that on ' Unsolved Problems in the Design and Propulsion of Ships ', given by Dr Francis Elgar in 1907 but throughout the entire series of lectures research has been given great prominence, and in the opening of the thirty seventh James Forrest lecture, delivered at the Institution of Civil Engineers on May 5 of this year, Sir Thomas Stanton stated that his immediate object was ' to trace the changes which have taken place in the nature of the subjects studied in engineering laboratories from the date of Sir Alexander Kennedy's lecture in 1896 to the present time "

Forty years ago almost all engineering laboratories were attached to educational establishments and were simply physical laboratories modified for engineering purposes Problems of engineering research, however, became of a more ' physical ' nature, and in consequence engineering laboratory methods had to some extent changed their character, while engineering laboratory research is becoming more and more detached from engineering education

The matters discussed by Sir Alexander Kennedy were concerned almost entirely with the performance, economy, and efficiency of machines and prime movers work admirably adapted to meet the urgent educational need of that time, but the scope of modern investigatory work in engineering can be illustrated by a review of problems of interest studied recently at the National Physical Laboratory The work of the Engineering Department of the Laboratory can be divided into three groups (a) Government research done for research committees and boards of the Department of Scientific and Industrial Research, for certain research associations, for the Air Ministry, the War Office, the Ministry of Transport, and other Government civil departments (b) researches forming part of the general programme of the Laboratory Research Committee and (c) special investigations for the general public The latter work is undertaken at a scale of fees determined by the measure of publicity which clients are willing to allow to the Laboratory report Under group (b) were included in 1929 investigations of the efficiency of power transmission by gears, of hardness tests of materials, of stress distribution in reinforced concrete columns due to shrinkage, of the properties of waves set up by wind blowing over water, of vortex rings discharged in the wake of a disc immersed in a stream of fluid, and of the variation of pressure in steel cylinders containing dissolved acetylene as the temperature is raised

No fewer than twenty four subjects were included in the Government research programme in 1929, among these being investigations on lubrication, the transmission of heat, the ignition of gases by sudden compression, the fatigue phenomena exhibited by single crystals of metals, the bearings of aircraft engines, the endurance of laminated springs as found in motor vehicles, the mechanical properties of materials at high temperature, the resistance of projectiles, the pin joints of caterpillar tractor track shoes, the efficiency of motor lorry gear boxes, the distribution of wind pressure on roofs, the mixing and laying of concrete roads, and the friction of road surfaces Special investigations carried out in 1929 dealt with ceiling fans, steam pipe coverings, safety glass, brake linings, ball and roller bearings, the vibration of buildings, and the action between white metal alloys and lubricants

One piece of work of a novel and interesting character has arisen out of a visit to Paris in 1918 by the British Ballistic Mission, who saw there apparatus in which a model projectile was exposed to a momentary jet of air at high speed At the National Physical Laboratory it was found that the construction of a continuously flowing current of air up to twice the speed of sound presents far fewer difficulties than those experienced with the momentary jet, and a three-inch diameter wind channel has been developed in which the head resistance of model projectiles can be measured at speeds up to three times that of sound, and relative values due to changes in the design of the head and base of the projectile can be determined

One of the most striking developments of recent years is the increase in the application of the method of scale model testing to the solution of engineer-

ing problems The method was foreshadowed by Newton in the "Principia", and the theory was extended by Stokes, Helmholtz, Froude, James Thomson, and Osborne Reynolds The foundations of the method were laid by these pioneers, and the last forty years has witnessed the continued growth of its application to a wide range of problems Sir Thomas Stanton stated that he did not intend to put forward arguments for their extension, he believed that what is wanted is a somewhat more critical review than has hitherto been attempted of the implications of the method and of the extent to which engineers may rely on the predictions to full scale made from them He dealt with the principle involved in scale model testing, and illustrated it by reference to the prediction of the resistance of a ship, the hydraulic resistance of pipe lines, and the prediction of the wind resistance of roofs and bridges

The concluding part of the lecture contained a review of the present position of engineering research in Great Britain Sir Richard Glazebrook, in his James Forrest Lecture in 1923, reviewed then the conditions, and the most notable step taken since has been the formation of an important Research Department of the Ministry of Transport under the Roads Improvement Act, 1925, and the inauguration in 1930 of a research station at Harmondsworth This will probably be the largest engineering research laboratory in Great Britain There remains the important consideration of whether the financial provision for engineering research is adequate A comparison of Great Britain with other European countries is difficult on account of the lack of definite information, but a comparison with the expenditure on research in the United States shows that the sum we spend is of very modest proportions Research, however, is being encouraged in various ways and Sir Thomas Stanton said, "taking into consideration the sympathetic attitude of the Research Department, we may, I think, conclude that, apart perhaps from research in aeronautics and metallurgy, the existing provision for general engineering work is adequate, and that should further provision be considered advisable for investigations of national importance, the Department may be relied upon to give all the help that can be made available"

The Royal Institution

THE president, Lord Eustace Percy, and Managers of the Royal Institution went direct to the core of old English custom when they invited the members and other visitors, representative of the diplomatic and public services, science, arts, literature, and medicine, to a "House Warming" in Albemarle Street It was held on May 6, and was largely attended Fleetwood, in an epistolary of 1577, says, "The shoemakers of London having builded a newe Hall, made a royall feast for theire friends, which they call theire house warming" Then, Evelyn chronicles, under date Nov 28, 1661, "I dined at Chiffinch's house warming in St James's Park", and in a number of the *Spectator* for 1712, the following occurs 'I must make the present entertainment like a treat at an house warming, out of such presents as have been sent me by my guests"

The primary object of the house warming was, of course, to demonstrate the realisation in material form of the reconstruction effected in the Royal Institution It has long been recognised that rebuilding and a readjustment of certain parts to modern needs was a real necessity This applied particularly to the Lecture Theatre, which remained much as it was since completion in 1802, an auditorium, moreover, constructed entirely of timber We think that the Managers are to be congratulated on preserving so much of the old time atmosphere of this historic room, the scene of the early experiments of Davy and Faraday and their successors The scientific equipment of the theatre has now been considerably extended a cinematograph projector and an epidiascope have been installed, together with many technical desiderata essential for the proper and convenient elucidation of lecture subjects

FIG 1—New Entrance Hall, Royal Institution

The rebuilding of the Lecture Theatre has

naturally involved the replanning and reconstruction of a large adjacent part of the building The ante room on the first floor has been enlarged and redecorated in excellent taste Opening from this is the ambulatory, around which, beneath the seating of the theatre, well-lighted showcases for historic apparatus in the possession of the Institution have been arranged Opening from the opposite side of the ante room is a long corridor giving access to the Far Library and also to the Davy Faraday Research Laboratory

A new entrance hall has been constructed, and this is supplementary to the fine old entrance hall, and staircase, adjacent which was in existence in 1799 at the foundation and occupancy of the building A large new chemical laboratory has been built on the ground floor, and some of the rooms replanned, to enable an exit from the Lecture Theatre direct to the street to be made The basement area has been rearranged, and contains the workshops, the equipment for the distribution of electric power throughout all parts, and the heating and ventilation plant The new heating system in operation is entirely electric

An interesting programme was arranged for the house warming All parts of the Institution were open to guests, including the director's flat on the second floor, which contains Faraday's study Sir William Bragg gave demonstrations in the Lecture Theatre, comprehended in the title "Classical Experiments of the Royal Institution' He showed Davy's experiments on the decomposition by electrolysis of potash to obtain metallic potassium Faraday's experiment on the induction of electric currents in a coil by the movement of a magnet into and out of it was shown, his 'great cube' experiment, to show that electricity resides on the outside of a conductor, was also demonstrated, for which purpose a small wire cage was erected in the Lecture Theatre This experiment must have been described in hundreds of text-books, but there are probably not many who have seen a person sitting unharmed inside an electrified cage while sparks are drawn from the outside Rayleigh's experiment on the production of a sound shadow was also shown, the sound waves from a bird call were obstructed by a glass disc, on the other side of which a sensitive flame gave a response only when on the axis of the disc, due to a diffraction effect of the sound waves In relation to Sir James Dewar's low temperature work, a diamond was heated in a crucible and thrown into a dish of liquid air, where it burnt, deriving oxygen for combustion from the liquid air The historical apparatus in the keeping of the Institution was displayed and supplied with full descriptive particulars In addition, there were exhibits and experiments in the Davy Faraday Research Laboratory illustrating the latest developments in the technique of X-ray crystal analysis, these included a demonstration of the rotating cathode X ray tube developed by Dr A Muller

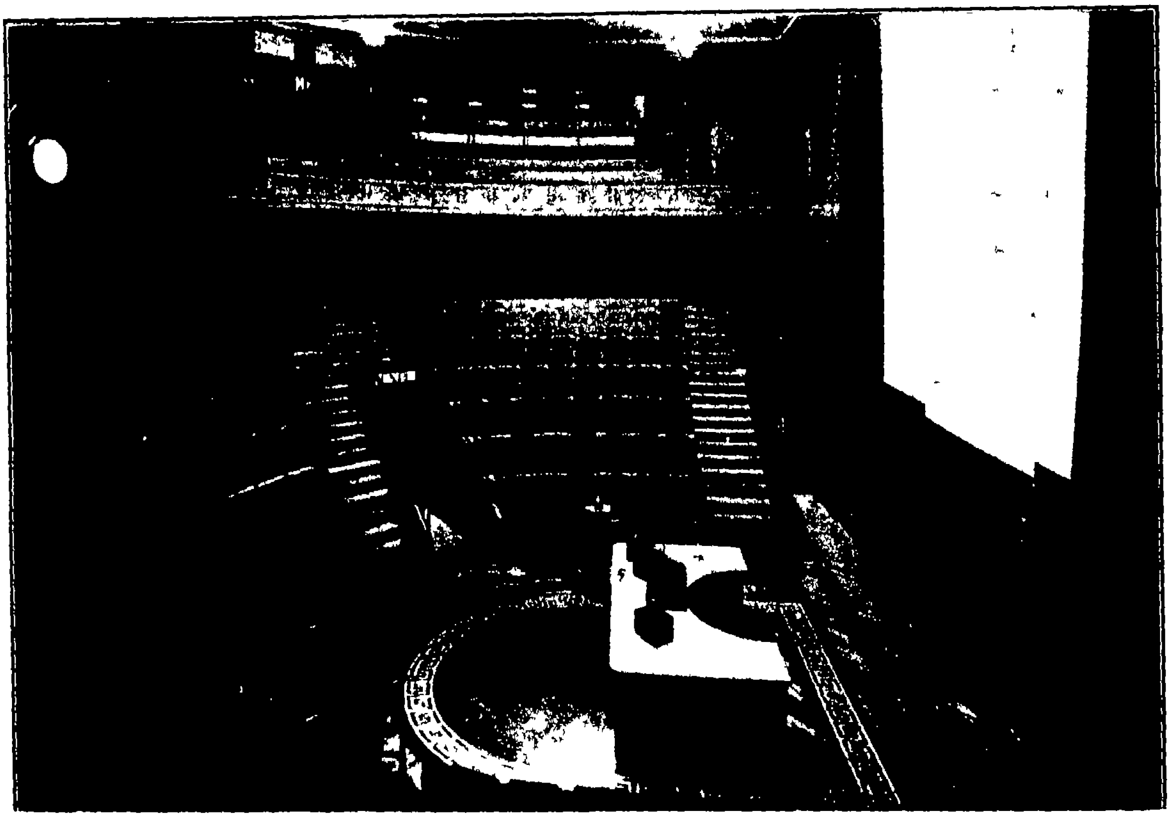

FIG 2 Lecture Theatre Royal Institution

Obituary

PROF A A MICHELSON, FOR MEM R S

WE much regret to announce the death, which occurred on May 9, of Prof A A Michelson, the distinguished physicist of the University of Chicago Prof Michelson was probably best known for his wonderful experimental work to detect any effect of the earth's rotation on the velocity of light At the end of 1929, he resigned his position at the University of Chicago and went to Pasadena, where he proposed to carry out further work on this subject, and it is reported that preliminary measurements have already been made Prof Michelson had worked previously at Mount Wilson Observatory, Pasadena, and a brief account of repetitions of the famous Michelson Morley experiment, as it is generally called, with a diagram of the apparatus, was contributed to NATURE of Jan 19, 1929, by him and his collaborators The results then obtained showed no displacement of the interferometer fringes so great as one fifteenth of that to be expected on the supposition of an effect due to a motion of the solar system of three hundred kilometres per second through the ether Since then, Prof Michelson has been awarded the Duddell Medal for 1929 of the Physical Society of London for his work on interferometry

In NATURE of Jan 2, 1926, we were fortunate in being able to publish, as one of our series of "Scientific Worthies", an appreciation of Prof Michelson and his work by Sir Oliver Lodge We print below extracts from that article

"Albert Abraham Michelson was born in Strelno, Poland, on Dec 19, 1852 In 1854 his parents migrated to the United States After emerging from High School in San Francisco, young Michelson was appointed to the Naval Academy, from which he graduated in 1873, and two years later became instructor in physics and chemistry under Admiral Sampson, continuing this work until 1879 After a year in the Nautical Almanac Office at Washington, Michelson, now an ensign, went abroad for further study at the Universities of Berlin and Heidelberg, and at the Collège de France and the École Polytechnique in Paris Upon his return to the United States in 1883 he became professor of physics in the Case School of Applied Science, Cleveland, Ohio, whence, after six years, he was called to Clark University, where he remained as professor until 1892, when the University of Chicago opened its doors Prof Michelson went to this new institution as professor of physics and head of the department In June 1925 he was honoured by being appointed to the first of the Distinguished Service Professorships made possible by the new development programme of the University

"It was while he was at Cleveland that Prof Michelson collaborated with Prof Morley in their joint experiment, and it may have been for the purpose of that experiment that he invented his particular form of interferometer, with the to and-fro beams at right angles Later, he applied it in Paris to the determination of the metre, with an estimated accuracy of about one part in two million

"During the War, Prof Michelson re entered the Naval Service with the rank of Lieutenant-Commander, giving his entire time to seeking new devices for naval use, especially a range-finder, which became part of the U S Navy Equipment

"A Nobel Prize was awarded to Prof Michelson in 1907, the first American to get one for science, and the Copley Medal, the most distinguished honour of the Royal Society of London, was awarded him in the same year

"The gold medal of the Royal Astronomical Society was presented to Prof Michelson on Feb 9, 1923, and the compact exposition of the reasons for that award, by the president, Prof Eddington, on that occasion will be found in NATURE, vol 111, p 240

"Michelson touched on many departments of physics, but in optics, the highest optics, he excelled In this subject he can be regarded as the most fertile and brilliant disciple of the late Lord Rayleigh, for his inventions are based on a thorough assimilation of the principles of diffraction, interference, and resolving power, and his great practical achievements are the outcome of this knowledge Michelson seemed to have a special instinct for all phenomena connected with the interference of light, with a taste for exact measurement surpassed by none in this particular region The interferometer with which he began became in his hands much more than an interferometer He applied it to the determination of the standard metre in terms of the wave length of light, with exact results which will enable remote posterity millions of years hence to reconstruct, if they want to, the standard measures in vogue at this day He applied it also to analyse the complex structure of spectrum lines, and with remarkable completeness to determine the shape and size of invisible objects, such as to ordinary vision, however much aided by telescopic power, will probably remain mere points of light

"In a magnificent paper in the *Phil Mag* of July 1890, Michelson suggested the application of interference methods to astronomy He knew well that the resolving power of a telescope depended on the diameter of its aperture, and that the formation of an image was essentially an interference phenomenon, the minuteness of a point image, and therefore the clearness of definition, depending on the size of the object glass But he pointed out that if the aperture was limited to slits at opposite edges—so that no actual image anything like the object would be formed, but only the interference bands which the beams from the two slits could produce—a study of those bands would enable us to infer about the source of light very much more than we could get by looking at its image For example, suppose it was a close double star, and suppose the slits over the object glass were movable,

so that they could be approached nearer together, or separated the whole distance of the aperture apart A gradual separation of the slits would now cause the fringes to go through periods of visibility and invisibility, and the first disappearance of the fringes would tell us that the distance apart of the two components of the star (multiplied by the distance between the slits and divided by the distance of the star) would equal half a wave length of light The two components might be far too near together ever to be seen separately, and yet we could infer that the star was a double one, and by further attention to the visibility curve we could infer the relative brightness of the two components and their position relative to our line of sight

Furthermore, if, instead of looking at a star, we turned the slit provided telescope on a planet with a disc too small for ordinary measurement, the size of that disc could be estimated from the behaviour of the interference fringes produced by its light in a suitable interferometer, or by the telescope converted into one

In view of the great interest aroused by the application of this method by Michelson himself, with the aid of collaborators at Mount Wilson Observatory Pasadena, California, and with the hundred inch telescope established there, it may be interesting to quote here part of the conclusion of his paper of date 1890

' '(1) Interference phenomena produced under appropriate conditions from light emanating from a source of finite magnitude become indistinct as the size increases, finally vanishing when the angle subtended by the source is equal to the smallest angle which an equivalent telescope can resolve, multiplied by a constant factor depending on the shape and distribution of light in the source and on the order of the disappearance

" '(2) The vanishing of the fringes can ordinarily be determined with such accuracy that single readings give results from fifty to one hundred times as accurate as can be obtained with a telescope of equal aperture '

' If among the nearer fixed stars there is any as large as our sun, it would subtend an angle of about one hundredth of a second of arc and the corresponding distance required to observe this small angle is ten metres, a distance which, while utterly out of question as regards the diameter of a telescope objective is still perfectly feasible with a refractometer There is, however, no inherent improbability of stars presenting a much larger angle than this and the possibility of gaining some positive knowledge of the real size of these distant luminaries would more than repay the time, care, and patience which it would be necessary to bestow on such a work '

' There seemed little hope at that time, and certainly no reasoned expectation, that any stars except perhaps some of the very nearest, could have discs big enough for perception and measurement even by this virtual telescope of thirty feet aperture The possibility of giant stars came, however, above our mental horizon, and Eddington made the notable prediction that a star like Betelgeuse must be in a highly rarefied state at a tremendously high temperature, and that it would be swollen out by the pressure of light to a size almost comparable with the dimensions of a solar system, although it could not contain very much more matter than, say, two or five times our sun His argument, in brief, is that the spectrum of a young red star like Betelgeuse shows that it cannot be radiating furiously Why then is it so conspicuous an object to our vision? It can only be because it is of enormous size, its density perhaps a thousand times less than atmospheric air By utilisation of the data available in the light of his theory of stellar constitution, Eddington made an estimate of the diameter of the star

'So with great skill Michelson and his collaborators got the interferometer to work After many preliminary adjustments, on Dec 13, 1920, Dr F G Pease at Mount Wilson, with Michelson's apparatus, measured the diameter of a star for the first time, using Betelgeuse for the purpose The interference fringes formed by the star were observed, the object mirrors were gradually separated, and it must have been a joyful moment when, as they grew farther and farther and farther apart, the fringes at the eye end became less distinct and ultimately disappeared The distance apart of the mirrors now, multiplied by the proper fraction, gave the angular dimensions of the star—a thing which had never before been observed in the history of the world An estimate of the star's distance gave its actual diameter, and confirmed Eddington's prediction!

Other stars have since been measured, and the giant stars well deserve their name Moreover, an instrument has been put in the hands of posterity to the power of which we can scarcely set a limit in investigating utterly invisible details, both about the heavenly bodies and about atoms, by the new and powerful method of analysing the radiation which they emit

' The form of instrument adapted to the heavens is, however, not applicable to the atoms The spectrum of atomic radiation is formed by a grating, and Rayleigh showed that the power of a prism spectroscope is expressed approximately by the number of centimetres of available thickness of glass, which is one form of saying that, to get high definition or separating power, we must use interference depending on a great number of wavelengths retardation Michelson perceived that the retardation principle might be employed so as to make a grating which combined with its own effect the resolving power of a prism A slab of glass, a centimetre or more thick, might be used to give the necessary lag in phase of many thousand wavelengths, and thereby secure a definition and resolving power unthought of before So Michelson designed the Echelon spectroscope, consisting of thick slabs of glass, each protruding a millimetre or so beyond the other—a staircase spectroscope—which is now a regular instrument in the examination of the minute structure of spectrum lines

"What, however, is popularly the best known

work of Michelson is the application of his interferometer to determine if possible the motion of the earth through the ether The speed expected was of the order one ten thousandth of the velocity of light but since the journey of the light in the instrument is a to and-fro journey—one half-beam going as nearly as possible with and against the hypothetical stream of ether, while the other half beam goes at right angles to that direction—the amount to be measured was not one-ten thousandth but the square of that quantity, that is to say, the observer had to measure one part in a hundred million—no easy matter The interferometer was mounted on a stone slab floating in mercury, and the whole observation conducted with great care The result was zero, and that zero was used afterwards as the corner stone of the great and beautiful edifice of relativity"

WE regret to announce the following deaths

Mr St George Littledale, who was awarded the Patron's Medal of the Royal Geographical Society in 1896 for three important journeys in the Pamirs and central Asia, on April 16, aged seventy nine years

Sir Charles Lucas lately chairman of the Royal Empire Society (formerly the Royal Colonial Institute), distinguished as a historian of British colonial development, on May 7 aged seventy seven years

Mr Emil Torday a distinguished authority on the anthropology of Africa on May 9, aged fifty six years

News and Views

THE question of the introduction of twenty four hour reckoning for railway time tables has recently been discussed in Parliament The subject is a well worn one It is nearly half a century since the late Sir William Christie made efforts in this direction He suggested that, if it were done, astronomers might meet the public by reckoning astronomical time from midnight, a change that was actually made in 1925 A few years ago a committee appointed by the Council of the Royal Astronomical Society interviewed the railway authorities, endeavouring to persuade them to adopt the 24 hour system in time tables, pointing out that the method was already in use in many countries The companies, however, refused to make the change unless clear evidence was submitted to them that the public desired it It is, however, fairly obvious that the public is inarticulate in matters of this kind There was little enthusiasm for the summer time scheme until it came about as a war time economy, but once it was tried it was welcomed with enthusiasm by all except a small minority If the 24 hour scheme were adopted there would be no need to have new clock dials, the addition of 12 hours is an easy mental operation moreover, the use of the new time for time tables and public announcements would entail no obligation to use it in private life

FOR some little time the attention of the public has been specially directed to eastern affairs in such a way as to emphasise the need for appreciation of the distinctive features in Oriental culture as a basis of understanding More recently, however, the success of the exhibition of Persian art has given undue stress to the æsthetic side, which scarcely comes within the scope of NATURE It is for this reason that we have refrained from comment on the various suggestions for the foundation of a museum for Oriental or Asiatic art which have appeared in the correspondence columns of the daily press A proposal of a more comprehensive and scientific character is now put forward by the Royal Anthropological Institute At a recent meeting of the Institute's Joint Committee on Teaching and Research, which includes representatives from all the universities and institutions interested in anthropological and archæological studies, it was strongly urged that a central institute is needed to serve and guide the study of Indian and Oriental cultures as an expression of the thought and life of the people and that such an institute should include, as recommended by the Royal Commission on the National Collections, provision for the study and exhibition of the national collections from the scientific and technological as well as from the æsthetic point of view It was added that provision should be made in the Institute for the endowment of advanced teaching and research, and that its constitution should be on a federal basis, to permit the closest co operation with existing institutions devoted to such studies

THE bearing of the last suggestion is elaborated in a memorandum by Prof J L Myres which was circulated to the Committee and is published in *Man* for April It is there pointed out that the provision of a chair of Indian cultural studies, which has been suggested, is scarcely practicable, in view of the wide range of studies to be covered, while a series of chairs "in some British University' would not necessarily stand in the desired relation to the national collections On the other hand, there are in other university cities, as well as in London, long established and well supported centres of Oriental study such as the Indian Institute at Oxford This institute, as founded by Monier Williams, did indeed, on a small scale, anticipate the combination of library, museum, and provision for teaching and research such as is now contemplated and could alone cover adequately the study of art and technology, illustrate the thought and social structure of the people, and in the literature provide the interpretation of their culture A national institution of the type suggested might then be linked federally to all existing establishments by the structure of its directorate and the composition of its staff

THE Patent Office has recently made changes in the method of publishing its abridgments of specifications which should be noted by all who have to search through British patent literature Hitherto, the weekly official journal has always contained, in numerical sequence, the week's series of abridgments, the whole from year to year forming a complete numerical set for immediate reference purposes In addition, the abridgments allotted to each of the 271 classes into which the subject matter of inventions

is divided by the Patent Office have been collected together in five year periods and issued in class volumes with name and subject indexes Under the new arrangement, which came into force this year with specification No 340,001, the publication of the abridgments in the official journal has been discontinued, and they will now be issued only in separate weekly instalments divided into 40 groups, each of which comprises a carefully selected number of the old subject classes, when the whole series includes 20,000 abridgments (that is, roughly, every year), the abridgments of each group will be issued in volume form with their appropriate name and subject indexes The official journal contains each week a numerical list of the accepted specifications showing the groups in which the respective abridgments will appear

IT is too early to say whether the change which has been made in the method of publication of patent specifications will be appreciated by searchers The old arrangement provided a very ready reference to individual cases and a useful continuous record for libraries and others who had no space for the series of full specifications But, on the other hand, it was not particularly handy for a current subject search, and the old volumes of class abridgments lost a good deal of their usefulness by appearing so late The new group volumes will be considerably larger than the old ones, but the sheets will appear within a few weeks of the acceptance of the specifications and should thus prove of greater value for current search purposes (especially if the 'opposition' period is extended as is suggested by the recent Departmental Committee), and their separate subject indexes will replace the present annual consolidated subject index The annual accumulation of the group allotment lists which are printed in the journal each week will continue the numerical sequence of the earlier series of abridgments

THE annual report of the Council of the Institution of Professional Civil Servants again records a large increase in the membership of the Institution, which during 1930 rose from 6560 to 8452 It is noteworthy that, quite apart from 'observer' and 'technical assistant' staffs, the latter figure includes 1243 members of full scientific status employed in the various scientific branches of the Civil Service The outstanding feature of the year's activities was the submission to the Royal Commission on the Civil Service, which is now sitting, of a comprehensive statement of evidence embodying the Institution's case for a far reaching reorganisation of the scientific and technical services of the State It was urged that the existing multiplicity of professional, scientific, and technical grades should be rationalised and replaced by a simplified graded technical service As regards the relationships between administrative and technical staffs, it was proposed (1) that the respective functions of the technical and the non technical officers of the service should be redistributed in a manner which would give the expert wider powers of administration in his own department and enlarge the limits of his authority in regard to expenditure and the handling of staff, and (2) that arrangements should be made to ensure that the parliamentary head of a department is always fully aware of the views of his technical advisers In cases where the board system is not in operation, right of access to the Minister on all important questions involving technical considerations should be unconditionally vested in the heads of professional, scientific, or technical hierarchies In a friendly reference to the work of the Association of Scientific Workers, the Council expresses the hope that all eligible members of the Institution will become members of the Association, which, it states, is "the only body actively bringing the claims of the scientist to the notice of the public" Emphasis is laid on the essential unity of the scientific and technical services of the State

THE measurement of noise was the subject of the discourse given at the Royal Institution on May 8, by Dr G W C Kaye, superintendent of the Physics Department, National Physical Laboratory The 'yardstick' or 'degree' by which we measure noise is the decibel, a simple power ratio or logarithmic unit (NATURE, Jan 10, p 75) Although the measurement of noise is of considerable complexity, being bound up in part with physiology and psychology, the physics of acoustical measurement has made great strides both in facility and exactitude This is largely owing to the development of electrical methods based on the invention of the electronic valve By such means, noises can be analysed into spectra showing their frequency components, and their loudness can be measured physically by the microphone A convenient 'noise thermometer' ranges from 0 to 100 decibels, an upper level which is unlikely to be exceeded in everyday experience Conversational level is at about the half way point, 50 db The value for a quiet suburban street is 30 db, for a tube train 80 db Loudness levels of everyday noises have been determined by the National Physical Laboratory and by the Bell Telephone Laboratories and others in the United States New York traffic noises, both in the street and in the Underground, appear to be about 10 decibels louder than in London A modern car is quieter than a horse vehicle on a paved street Among the loudest things one is likely to encounter are the noises of rivetting, pneumatic road drilling, steamship sirens, and printing presses, but the arch offender of all is the aeroplane engine at close quarters (110 db) The noise in the cabins of aeroplanes in flight ranges between 80 db and 110 db, according to the type of machine There are, however, good prospects that the noise in aeroplane cabins will presently be substantially reduced (possibly to that of a railway train) by using propellers with lower tip speeds, providing more effective silencers on the exhausts, reducing engine clatter by enclosing the engines, and constructing cabins of double walls containing a suitable filler The question of protection from noise is being investigated at the National Physical Laboratory, and new sound-laboratories are to be erected in the near future

IN *Engineering* for April 24, a description is given of a clock that apparently can go on continuously until any part wears out It was made by T Dieden, of Carlslund, Sweden, and has already been going for fourteen years Although a self winding clock, it is a very near approach to perpetual motion In its main features it is very similar to an ordinary clock, having a driving weight, a train of wheels driving the hands, and a torsion pendulum consisting of a heavy metal disc suspended by a thin steel ribbon The unique feature of the clock lies in the method employed for winding up the driving weight The power is obtained by the ordinary variations of the atmospheric pressure and temperature The case of the clock contains seven closed elastic metallic boxes of the type used in an aneroid barometer The lower box is attached to the case, but the column of boxes is otherwise free The total expansion or contraction of all the boxes due to changes in the temperature or pressure is communicated to the top box This is connected to two pawls working in opposite directions When the column of boxes either increases or diminishes in height, the spindle carrying the ratchet wheels always rotates in the same direction and the driving weight is wound up Fixed pawls prevent the ratchet wheels from running back When the weight reaches its topmost position they are thrown out of action With its weight fully wound up, the clock can run for eighteen months without stopping, and it would be exceedingly unlikely for the temperature and pressure to remain constant over such a long interval The pendulum has a period of $7\frac{1}{2}$ seconds, so that the length of the equivalent simple pendulum is about 185 ft

THE Annual Report of the Zoological Society of London records a successful year the number of fellows has increased (from 8344 last year to 8430), the subscriptions of fellows have increased, the number of visitors to the garden in Regent's Park has increased, very considerably exceeding the two million mark, gate money has increased, and with it all the expenditure for the year has fallen, so that a favourable balance of £1479 is carried forward The health of the stock has been satisfactory, and the death rate is still moving, although almost imperceptibly, in the right direction Its decline should be hastened by the formation of an isolation ward, where epidemic diseases may be checked at the outset Chance injuries and accidents account for most of the deaths, 230, or 18 9 per cent Then follow diseases of the respiratory system, which, even when tuberculous and mycotic infections are excluded, account for 177 deaths, or 14 6 per cent, diseases of the digestive system follow with 166, or 13 7 per cent In addition to the isolation hospital, there have been created several new buildings, of which the parrot house and bird diving house, in the old refreshment room building, and the butterfly cage appeal most to the inhabitants and to visitors

PERHAPS readers will turn most eagerly to discover how the zoological park at Whipsnade is progressing Much has been accomplished since the last Report of the Zoological Society Hall Farm has been transformed into a restaurant, and the old fellows' pavilion has been transported from Regent's Park to the Downs More than three miles of internal roads have been made, four chalk pits, ultimately to become carnivore dens, have been excavated for road metal, much planting has been done, and already enclosures and paddocks are well stocked with a considerable variety of the larger birds and mammals As has already been announced, Whipsnade Zoological Park will be opened to the public on Saturday, May 23, the previous day being set aside as a private day for fellows of the Society and official guests Capt W P B Beal, late Principal Veterinary Officer of the Gold Coast, has been appointed Superintendent of the Park for one year

AT a special meeting of the Council of the Ray Society on April 30, the following resolution was adopted "The Council of the Ray Society desire to place on record the profound grief felt by them on hearing of the death of their President, Professor W C M'Intosh, F R S, on April 1st last Professor M'Intosh had belonged to the Society since 1863 and had been President since 1913 He had not only shown his practical interest in its success by his exceptionally long period of membership, but he had given the most devoted service to the Society by his frequent journeys from St Andrews to London, in order to attend the meetings of the Council, at which he nearly always presided The Council direct that this record of their appreciation of the value of their late President's work be sent to Dr R T Gunther, his nearest surviving relative, with the expression of their sincerest sympathy" Sir Sidney F Harmer, the treasurer of the Society, was elected president *ad interim* in succession to the late Prof M'Intosh

RECENT Norwegian work in the Antarctic region has resulted in several new discoveries of coast line Several years ago, Mr L Christensen detailed one of his ships, the *Norvegia*, for exploratory purposes New land was discovered to the west of Enderby Land, called Queen Maud Land, and to the north east of Coats Land, called Princess Martha Land News now comes of further discoveries in the southern summer that has just ended The *Times* recently recorded the discovery by Capt Riiser Larsen, flying from the *Norvegia*, of a further stretch of coast line between the two already mentioned This is Ragnhild's Land and extends from lat 68° 40′ S, long 33° 30′ E, to lat 70° 30′ S, long 24° 15′ E The *Geographical Journal* for April contains news from Mr Christensen of the sighting of more land, this time apparently to the east of Enderby Land and MacRobertson Land which Sir Douglas Mawson discovered The new coast line lies in lat 68° S and extends from long 65° E to 71° E Thus there appears to be a considerable bight in the coast of Antarctica between MacRobertson and Wilhelm Lands The *Norvegia* concluded the season's work by circumnavigating Antarctica and confirming the non existence of various doubtful islands

THE production of books seems to maintain its very high standard, especially in Great Britain and the United States, in spite of trade depression This is due probably to the large number who are

now taking advantage of the opportunities offered for advanced education, for, in spite of the great number of publications in fiction (by far the greatest of all) children's books, religion, biography and travel, and other books of a general character, which reach the same percentage in Great Britain and the United States, a good proportion of books is in the specific sciences. With the great advances made in aeronautics, there is a corresponding increase in the number of British publications, which according to the *Publisher and Bookseller*, reached the total, in 1930 of 133. Only 26 books on wireless appeared in 1930, topography and folk lore show a total of 205, while botany, horticulture, and agriculture stand at 176, anthropology 35 chemistry and physics 116, astronomy and meteorology 50 engineering sciences 115, geology 53 mathematics 37, medicine 456, zoology 163, and psychology 64. The total number of British books published in 1930 was 15,494 of which 3638 were new editions. It is gratifying to the man of science to note that the 209 limited editions still remain in the letters groups there being practically no such publications in science. According to the list of publications in the United States in 1930 which appears in the *Publisher's Weekly* the number of American books produced last year reached 10 027 of which 1893 were new editions. These figures are much below the corresponding figures for Great Britain.

IN the first of a new series of *Tyneside Papers*, issued by the Tyneside Council of Social Service, the trend of population in that area is compared with the results of an earlier survey published in March 1926. It was then pointed out that population was growing more rapidly than industry was expanding and that a new equilibrium would be brought about slowly through (1) a further decline in the birth rate, (2) further migration, (3) a partial recovery in the old staple industries, and (4) the expansion of minor industries and the starting of new industries. So far, the staple industries have not recovered, and, apart from the electrical industry, there has been little expansion of other industries. The situation, however, has entirely changed in regard to the birth rate and migration. The average yearly natural increase in population for the years 1926–29 was only two thirds of what it was in the earlier period 1921–26. In the second period, the annual outward balance of migration from Tyneside was about six times as much as that in the first period, and, if this exodus should continue, it would do much to reduce unemployment. Many would naturally wish that the situation could be re adjusted by revival of local industries rather than by loss of population, and the question suggests itself whether some of the industries presumably absorbing the inflowing population in the south could not be established on Tyneside.

THE thirty sixth annual congress of the South Eastern Union of Scientific Societies will be held at Winchester on June 10–13, under the presidency of Sir J Arthur Thomson. The presidential address on "Some Natural History Problems of the Countryside", will be delivered in the Guildhall on June 10. The various sections will open their sessions on the following days. Mr James Groves, president of the Botanical Section, will discuss ancient and modern stoneworts, in his presidential address. In the Archæological Section the president, Dr W E St L Finny will take as his subject the kings of Wessex, from Egbert to Athelstan. The president of the Geological Section is Prof H L Hawkins, who will discuss the nature, deposition, and palæontological implications of the Chalk. Mr J F Marshall, as president of the Zoological Section, will describe some stereoscopic photomicrographs of fossil insects to be exhibited by him in the Congress museum. Archæological surveys will form the topic of the presidential address of Mr H J E Peake before the Regional Survey Section. Several useful and interesting excursions have been arranged in connexion with the Congress. On June 13, the preservation of the countryside and the various parliamentary bills concerned with it will be discussed, Sir Lawrence Chubb and Sir Edgar Bonham Carter taking part in the discussion.

MESSRS Adam Hilger Ltd, the well known optical instrument manufacturers, have issued a pamphlet giving a general account of the products and aims of the firm and outlining the scope of its activities. The high quality of the Hilger products is generally recognised and the pamphlet reveals that the total value of the instruments exported by the firm during the last five years is three times that of the instruments supplied to the home market. The selected list of purchasers given at the end includes institutions from all parts of the civilised world. There is probably justification for the surmise that "most of the research of the world in certain fields of prime importance in modern physics is being done with Hilger instruments". Particular attention is given in the pamphlet to the industrial applications of scientific manufactures and there is an account of work of this kind connected with the metallurgical and chemical industries, mineralogical survey and the utilisation of ores, engineering design, the colour industries (paints, textiles, artificial silk etc), the manufacture of glassware and the manufacture of optical instruments (cameras, microscopes, telescopes, binoculars, etc). The publication is an interesting one, and the only point which calls for criticism is the retention of the accents and the capital initial letter in the word 'angstrom' used as a unit of wave length. It is time that the name of this unit took its place with 'ampere', 'henry', 'ohm', and many others of similar origin, as a common noun.

THE first of this year's Royal Society conversaziones will be held in the Society's rooms at Burlington House on Wednesday, May 20, at 8 30 P M.

SIR JAMES FRAZER, the distinguished anthropologist and author of "The Golden Bough", has been elected an Honorary Master of the Bench of the Middle Temple.

SIR ARTHUR KEITH, Hunterian professor and Curator of the Royal College of Surgeons, has been elected a foreign member of the American Philosophical Society, Philadelphia.

THE following appointments in the Colonial Agricultural Service have recently been made by the Secretary of State for the Colonies – Mr B J Weston, to be horticulturist, Cyprus, Mr J S Norman, to be field instructor, Federated Malay States

THE sixteenth of the public lectures on "Physics in Industry" arranged by the Institute of Physics will be delivered on May 19 at 4 30 P M, at the Institution of Electrical Engineers, by Mr Alan F L Chorlton, who will take as his subject "Physics in Relation to the Development of the Internal Combustion Engine"

IN NATURE for May 9, p 714 it is stated with reference to the Lancashire earth shake of May 3 that tremors were not registered at the Liverpool Observatory and Tidal Institute Mr H J Bigelstone, principal assistant at the Observatory, informs us that this is incorrect Tremors were recorded on the Milne Shaw seismograph there, commencing at 9 h 23 m 0 s and lasting 40 sec The maximum amplitude recorded was 1 5 mm

IT is reported in *Science* that Dr Werner Heisenberg, professor of theoretical physics at the University of Leipzig has been awarded the Barnard Medal of Columbia University Every five years the National Academy of Sciences recommends to the trustees of Columbia University a nominee for the Barnard Medal "for discoveries in physical or astronomical science or novel application of science to purposes beneficial to the human race" The previous recipients of the medal have been Lord Rutherford 1909, Sir William Bragg 1914, Prof A Einstein, 1921, and Prof Niels Bohr, 1925

THE Council of the Royal Society of Edinburgh has awarded the Makdougall Brisbane Prize, for the period 1926–30, to Dr Nellie B Eales Zoology Department, University of Reading, for her papers "On the Anatomy of a Foetal African Elephant" published in the *Transactions* of the Society The Bruce Preller Lecture to be delivered on July 6 by Prof Horace Lamb, will be devoted to a commemoration of the centenary of the birth of James Clerk Maxwell On June 15, Prof A H R Buller, professor of botany in the University of Manitoba, will address the Society on "Recent Advances in our Knowledge of the Higher Fungi"

THE International Institute of African Languages and Cultures has issued invitations to a congress to be held in Paris on Oct 16 19, when the Exposition Coloniale Internationale will still be open The Congress will deal with important linguistic and anthropological problems of the Africa of to day Prof Antoine Meillet, president of the Institut d'Ethnologie, will act as president of the Congress, and Prof Henri Labouret as vice president The Congress will be opened by Maréchal Lyautey and Lord Lugard will speak on the aims of the Institute The meetings will be held at Vincennes An interesting feature of the programme is a lecture by Dr Chauvet on African music, which will be illustrated by songs and dances by African performers Visits to the appropriate museums and collections are being arranged

THE Gold Medal of the Institution of Mining and Metallurgy has been awarded to Dr Charles Camsell, deputy Minister of Mines and Industries of the Dominion of Canada "in recognition of his untiring zeal and great ability in promoting the development of the natural resources of the Dominion and in furthering the general interests of the mineral industry" The following awards have also been made The Consolidated Gold Fields of South Africa, Ltd, Gold Medal to Mr C W B Jeppe, for his researches on mine ventilation at great depths, and for his paper on "Ventilation at the Crown Mines, Witwatersrand" the Consolidated Gold Fields Premium of forty guineas to Mr J G Lawford, for his "Notes on Some Stoping Problems in Mexico", and the William Frecheville Student s Prize of ten guineas to Mr W H Wilson for his paper on 'Bottom Slicing applied to Mining a large Irregular Replacement Deposit in Limestone"

IN a 4 page pamphlet Mr P I Harwood, of "Corona" Ovingdean Brighton, puts forward a theory of the Michelson and Morley experiment based on his definition of motion as 'a process of extending a body in a particular direction' which confers super extension on the body" and it acquires "a length longer than its static length" According to Mr Harwood, the increase of thickness of the mirrors in the line of motion compensates for the increase of the path of the light in that line He does not mention the increase of length of the support of the mirrors in the line of motion, which his theory of motion requires and his readers are left in the dark as to why the super extension is limited to the mirrors We have been unable to verify the author s statement that Sir James Jeans 'says that the sun, instead of sending us light waves, sends us nothing more substantial than mathematical equations"

MESSRS Bowes and Bowes, Cambridge in catalogue No 457 offer upwards of 400 books in new condition at greatly reduced prices The list is one of general interest, but in it are several works of a scientific character, particularly in the departments of archæology travel, and natural history

APPLICATIONS are invited for the following appointments on or before the dates mentioned – An organiser of agricultural education under the Middlesex County Council– The Secretary, Middlesex Education Committee, 10 Great George Street, S W 1 An assistant in the department of radium therapy and research of the Middlesex Hospital –The Secretary Superintendent, Middlesex Hospital, W 1 (May 20) A resident lecturer in mathematics, with physics, at the Borough Road Training College, Isleworth—The Principal Borough Road Training College, Isleworth (May 23) A head of the department of continuative education of Loughborough College—The Registrar, Loughborough College, Leicestershire (May 23) An assistant lecturer in economics at University College of the South West of England –The Registrar, University College of the South West of England, Exeter (May 25) A graduate teacher of electrical engineering subjects for the Junior and Technical Day School and Evening Classes of the Wandsworth

Technical Institute—The Secretary, Technical Institute, Wandsworth S W 18 (May 30) An assistant lecturer in chemistry at Brighton Technical College—The Secretary, Brighton Technical College, 54 Old Steine, Brighton (May 30) An assistant in textile research, for research work relating to the knitting industry, in the department of textiles of University College, Nottingham —The Registrar, University College, Nottingham (June 1) An inspector of explosives under the Home Office—The Private Secretary, Home Office, Whitehall, S W 1 (June 5) An assistant lecturer in physics in the University of Manchester—The Registrar, University Manchester (June 6) A lecturer in metallurgy an assistant lecturer in civil engineering, an assistant lecturer in electrical engineering, and an assistant lecturer in mathematics, each in the faculty of engineering of the University of Bristol — The Secretary and Acting Registrar, University, Bristol (June 9) A lecturer in agricultural chemistry and physics at Swanley Horticultural College for Women—The Principal, Swanley Horticultural College for Women, Swanley, Kent (July 6) A science mistress for physiology at the Bedford Physical Training College—Miss Stansfeld, Bedford Physical Training College, 37 Lansdowne Road, Bedford Two assistant organisers for help in the development of the Young Farmers' Club movement in the north and west of England respectively —The National Association of Young Farmers' Clubs, 26 Bedford Square, W C 1

Our Astronomical Column

Pluto —*Popular Astronomy* for April contains Prof V M Slipher's report on the Lowell Observatory, in which there are some more details about Pluto It was not until Feb 18, 1930, that Mr Tombaugh discovered the images on plates taken on Jan 23 and 29, and afterwards that on the plate of Jan 21 It was examined visually with the 24 inch refractor "No certain evidence of disk could be made out, although on a few occasions its image seemed not quite like those of equally faint stars" "Later tests indicated that with Pluto's faintness his disk, if as much as 0 6″, could escape detection under good observing conditions" This would imply a diameter of 11,000 miles It was found that Pluto was brighter visually than photographically, so a yellowish colour was inferred

The report also states that "the search of the ecliptic with the efficient 13 inch telescope is being continued by Mr Tombaugh A band of considerably greater width is being carried round the sky, and the reach in magnitude of stars included has been increased"

Rech Instit Circ 425 contains the following observations of Pluto made at Simeis by S Beljawsky

1931	U T	R A 1931 0	N Decl 1931 0
Mar 22^d	18^h 22 8^m	7^h 21^m 9 91^s	22° 20′ 39 4″
,, 23	18 12 0	7 21 8 99	22 20 45 6

The magnitude was 14 5 Prof M Wolf gave it as 14 on Feb 8

The above *Circular* also contains the following revised orbit of 1931 *FE*, which is the interesting minor planet discovered by Drs Schwassmann and Wachmann in March It is by A Kahrstedt

Epoch 1931 April 7 0 U T

$$\left.\begin{array}{ll} M & 31\ 20^\circ \\ \omega & 129\ 62 \\ \Omega & 1\ 20 \\ i & 24\ 26 \end{array}\right\} 1931\ 0$$

$\log q$ 0 2439

Period 3 713 years

The perihelion distance is 1 754, the eccentricity 0 2687

Spectroscopic Parallaxes of *B* type Stars —The Commonwealth Solar Observatory at Canberra has recently published *Memoir* No 2, containing an investigation of southern *B* type stars by B W Rimmer for determining spectroscopic parallaxes The method used by Rimmer is essentially the same as that of Edwards, who amplified an earlier method of Adams and Joy It consists in (*a*) accurately classifying the spectral types of the stars on the basis of the Harvard classification but with additional sub types interpolated, and (*b*) dividing each sub type into groups according to the sharpness of the spectral lines Both type and line sharpness are correlated with absolute magnitude, and the final results give reasonably good values of the parallaxes Struve has recently shown such methods to have a sound physical basis, also his parallaxes (derived from interstellar calcium lines) show a good correlation with the results obtained by them, though indicating that the dispersion of absolute magnitudes is probably too restricted Rimmer's method differs from that of Edwards in the formation of two extra groups, for bright line stars and peculiar stars, also, the instrument used gives spectra double the length of those obtained at the Norman Lockyer Observatory, Sidmouth, by Edwards For those stars, however, which are common to the two observers (170 in number) the parallaxes are in fairly good agreement A full discussion is given both of the instrumental equipment and the method used in deducing parallaxes The final results for 350 stars form a useful addition to our knowledge of stellar distances, being in numerous instances the only available source of information for southern *B* type stars This is the first volume of a purely astronomical character to be issued from Canberra, and it will be welcomed by astronomers

The Eighth Satellite of Jupiter —*Yale Astron Transactions*, vol 6, part 4, contains a new theory of this satellite by Prof E W Brown As is well known, the theory of this satellite is extremely difficult, owing to its great inclination and eccentricity and the very large solar perturbations Prof Brown has diminished these difficulties by the use of a doubly periodic intermediate orbit the two periods are that of the elliptic terms and that of the Variation The work was carried out before the recent recovery of the satellite, so the constants were derived from the observations of the first six or seven years The ratio of the mean motions (Sun to J VIII) is −0 171171, giving 741 613 days for the sidereal period, the mean inclination, 31° 13′ The eccentricity is at present taken as exactly 0 4 The mean motion of the perijove is −0 00163 *n*, where *n* is the mean motion of J VIII The perijove therefore takes more than 1200 years to make one revolution The fact of the motion being in the reverse direction to the satellite was unexpected, it arises from the second order terms exceeding those of the first order The mean motion of the node is −0 02193 *n*, hence the node goes round in about ninety years The coefficients of the inequalities are given in the article

Research Items

Stone Implements of Types new to Southern India.—Six stone implements of types not hitherto recorded in India are figured and described by K. Sripada Rao in the *Journal of the Mysore University*, vol. 4, pt. 2, July 1930. They are selected from among four hundred and fifty implements collected on geological excursions of the Central College, Bangalore. It is suggested that of the six types, four, from Reddipalle, Cuddapah District, of Cuddapah quartzite, represent an advance on the Lower Palæolithic (Acheulean) culture of Biligere, Mysore, while the last two, from Trichinopoly and Ranganathpur, Mysore, belong to the Middle Palæolithic. The first implement is triangular with incurved sides. One surface is concave and shows no sign of working, the other has a small central triangular platform of which the sides are parallel to the sides of the implement, giving it the appearance of a truncated triangular pyramid. Similar specimens were collected from widely separated areas such as Satyavedu, Alicoor Hills, and Kibbanhalli (Mysore). The nearest parallel is a 'tribrach' from the Isle of Wight, described by Sir John Evans, and compared by him to specimens from Yucatan and Russia. The second implement is roughly triangular with rounded angles and has one surface chipped in three broad triangular faces longitudinally disposed. It closely resembles the Stellenbosch 'cleaver'. The third implement is horseshoe shaped. The worked surface is covered by six broad flaked faces, the three big ones forming, with the back, the three straight cutting edges, of which the main one is opposite the curved edge of the horseshoe. The fourth implement is roughly rectangular. The worked surface (one side only) shows four big flakings, of which the one longitudinally disposed forms the cutting edge. Of the two remaining implements, the one from Trichinopoly, of yellow cherty material, is crescent shaped. The convex edge, 8¾ in. in length, is thin and sharp, the concave edge is also sharp. One end is pointed, the other has a ridge, and it is suggested that this was inserted in a handle to enable both edges to be used. The sixth implement, from Ranganathpur, is of white and greasy looking quartz reef, stained red by iron oxides. It is of the shape of an ox head with ledge like notches in the place of the ears. These make the implement probably unique in India and perhaps indeed elsewhere. It is suggested that the rounded and sharp-edged butt, which affords no hand hold, was intended to fit in a slotted handle.

Pneumoconiosis caused by Talc.—Although talc powder finds a number of industrial applications, comparatively few instances of pulmonary affections traceable thereto have been recorded. In the *Rendiconti* of the Reale Istituto Lombardo di Scienze e Lettere for 1930, Dr. Arturo Zanelli describes the case of a workman employed in a pneumatic tyre factory to inject powdered talc into the interior of the tyres and to apply the same material to the outer surfaces of the tyres by means of a cloth. During this work, the air contained a dense dust, but no masks were provided for the employés and no other means was adopted for their protection from the dust. The man developed grave digestive troubles, and X-ray examination of the lungs revealed the presence of the nodular formations typical of pneumoconiosis. Although talc has been regarded as a mineral forming a dust which only rarely has pathogenetic qualities, one of its properties seems to render it particularly dangerous. It forms extremely minute particles which do not irritate the sensitive nerve endings of the mucus on which they are deposited, so that such important means of defence as sneezing, coughing, and increased secretion are not brought into operation. In the case considered, indeed, the patient exhibited, during working hours, a weakening of the olfactory sense, the layer of dust on the mucus preventing the transmission of the olfactory stimuli to the nerve endings.

Respiration in Insects.—In *Biological Reviews* of the Cambridge Philosophical Society, vol. 6, No. 2, 1931, pp. 181-220, Dr. V. B. Wigglesworth gives an admirable summary of our present day knowledge of respiration in insects. A very extensive literature has grown round the subject during the last twenty years or so, and, in sifting this mass of information, the author has undertaken a task of considerable difficulty. His review covers the ground of external and internal respiration in insects: the histology of the tracheal system is fully described, while the supply of air to the tracheoles, the respiratory movements, the elimination of carbon dioxide, and the respiratory function of the blood all come under review. The respiration of aquatic insects is also very fully discussed, and there is a brief account of the same process in parasites. The ultimate endings of the tracheæ are capillary tubes, or tracheoles, often less than 1μ in diameter. The problem as to whether these fine tubuli contain fluid or air, a subject which Dr. Wigglesworth has specially studied, is discussed from its biophysical aspect. The exchange of gases in the tracheal system, as a whole, is effected primarily by diffusion, which is modified by the opening and closing of the spiracles. The relative importance of the spiracles and the integument with regard to the elimination of carbon dioxide is another important aspect of the subject, and it is evident that we know little as yet with regard to the rôle played by the skin. While there is indirect evidence that the blood acts as a carrier of oxygen to the tissues, it is still a very moot point whether it contains a respiratory protein analogous to hæmocyanin or hæmoglobin. It is only in certain very special cases that hæmoglobin is present in insects and functions as an oxygen carrier; but in the vast majority of these creatures no carrier has been identified. At the end of Dr. Wigglesworth's paper there is a bibliography, of about three hundred references, which will be found of service to all interested in the subject.

Indian Forest Plants.—In *Indian Forest Records* (Botany Series), vol. 16, pt. 1 (1931), Mr. R. N. Parker, forest botanist at the Research Institute, Dehra Dun, India, continues his illustrations of Indian forest plants with plates and notes of five more species of the genus *Dipterocarpus*. The first part of this work appeared in vol. 13, pt. 1 (1927), of *Indian Forest Records*, and was mentioned in NATURE, five species of this genus then being dealt with. The species here treated of are: *D. Baudii*, *grandiflorus*, *obtusifolius*, *Dyeri* and *Kerrii*. Excellent plates depict the species. Mr. Parker has an interesting note on the hybridisation of different species. He writes: "I am of opinion that the various species of Dipterocarpus hybridise freely in nature. The hybrids most often met with appear to be between the *ins* (rough barked dipterocarps), *D. obtusifolius* and *tuberculatus*, and one of the *kanyins* (smooth-barked dipterocarps)." The hybrids *D. costatus* × *obtusifolius* and *D. tuberculatus* × *turbinatus* seem to be of frequent occurrence. Other hybrids also appear to occur, though the evidence for them is not always very satisfactory. Dr. Kerr, a botanist

keenly interested in the Malayan flora, was the first to detect and describe a hybrid *Dipterocarpus*

New Arctic Islands —The Arctic seas between Franz Josef Land and Northern or Nicholas Land have seldom been penetrated, owing to congestion of heavy ice The *Italia* airship passed over the region in 1928 but made no discoveries In the summer of 1930, the Russian Arctic expedition under Prof O Schmidt, in the icebreaker *Sedov*, after relieving the meteorological station at Hooker Island, Franz Josef Land made an attempt to reach Northern Land, of which the western side is unknown In spite of heavy ice, the expedition had a great measure of success and made several discoveries of importance An account of the voyage by Prof. R Samoilovitch, with a map of the discoveries, appears in *Petermanns Mitteilungen* Hefte 3/4 1931 A low, flat island of Palæozoic sandstone (Wiesse Island) was found in lat 79° 27′ N 76° 40 E A second island, Issatschenko Island was found fifty miles south east of the island known as Einsamkeit or Lonely Island which however was not seen A third island called Voronin Island was found in lat 78 N long 93 30′ E (approximately) Farther north, a number of small islands of Palæozoic limestone were discovered about fifteen miles from the west coast of Northern Land On one of these islands of the Kamenev Group in lat 79 6′ N, long 90 33′ E a new meteorological station was established and provisioned for three years The party of four men is provided with dogs and could retreat to the Siberian coast if relief by ship were impossible Finally, the expedition discovered another island Schmidt Island, in lat 81 5 N, long 89 40′ E This island is completely ice covered

The Idu (Japan) Earthquake of Nov 26, 1929 —A preliminary report on this earthquake by Prof A Imamura (*Tokyo Imp Acad Proc*, vol 6, pp 419 422, 1930) shows that it presented phenomena of much interest The shock was destructive in two areas, the centres of which are about 14 miles apart Of the faults that appeared with the earthquake, three are especially noteworthy One, about 6½ miles long runs north and south along the neck of the Idu peninsula The dislocation along this fault in a railway tunnel shows that, at a depth of 500 feet, the crust on the west side had shifted 7 ft 10 in southwards and 2 ft downwards with reference to the other At the surface the dislocation was much less apparent The other two faults may be continuations of this fault that at the south end being 11 miles long and trending S 30° W The crust on its west side was shifted relatively 4 ft 3 in to the south with an upthrow of 1 ft 8 in The fault at the north end is much smaller and trends to the north west The seismographic evidence shows that the first movement came from near Ukihasi (lat 35° 2′ N, long 139° 0′ E) The block movement thus seems to have started near the central point of the fault system passed quietly over the middle fault, and increased greatly along the two oblique terminal faults Round these faults are situated the two meizoseismal areas, in which 259 persons were killed and 2142 houses destroyed About 4½ miles to the east of the southern area lies the small town of Ito, at and near which were felt the numerous slight shocks of the previous spring (NATURE vol 126, pp 326, 971, 1930) About the time of the Idu earthquake the Military Land Survey was engaged in relevelling the district One section was levelled the day before the earthquake and in the opposite direction the day after A comparison of the two series showed that practically no change had occurred in this portion of the peninsula The relevelling and retriangulation of the whole area are now in progress and seismographs have been erected at four stations around the epicentres (*Tokyo Imp Acad Proc*, vol 6, pp 399 400, 1930)

High-Speed Wind Channels — A paper by Sir Thomas Stanton in the March number of the *Proceedings of the Royal Society* contains a history of recent progress in the development of high speed wind channels for research in external ballistics The fundamental idea of the work is to measure the forces and couples to which a projectile is subject, by means of scale models in which the body is held stationary in a current of air moving at high speed The earlier work was done with the momentary blasts of air which were produced by the release of a volume held at high pressure, this proved unsatisfactory, partly because of the difficulty experienced in obtaining speeds greater than that of sound but more particularly because it was found that complicated systems of stationary waves formed in the jets so that it would be almost impossible to know the exact conditions to which the model was subjected The later work has been carried out in a continuous air current and it has now been found possible to devise systems in which the air current is reasonably uniform over a sufficiently large region to contain a small model, and in which the forces on the model can be measured with relative ease A considerable amount of investigation has been done on these lines but it has been found that the conditions in the channels are extremely sensitive to quite small changes in the entering air This rather limits the usefulness of the method, and it is suggested that the next stage in the work should consist in bringing such conditions under better control

Stark and Zeeman Effects —Two papers in the March number of the *Proceedings of the Royal Society*, by Prof J S Foster on the effects of electric and magnetic fields on the helium spectrum and by J K L MacDonald, on the Stark effect in molecular hydrogen in the range 4100 4770 A add considerably to knowledge of these phenomena Prof Foster's contribution is largely concerned with the combined effects of magnetic and electric fields a subject which has played an important part in the development of quantum theory but for which few data are available Amongst the numerous results may be noted the appearance of lines in crossed fields for which the change in the magnetic quantum number (Δm) appears to be more than one unit Mr MacDonald's paper deals only with the pure electric resolution of the band lines, extending and partly checking earlier work by Kiuti This investigation of molecular hydrogen is of considerable difficulty, both experimentally and in its theoretical interpretation In addition to the use of Lo Surdo tubes of rather curious design, with restriction of the path of the discharge in front of the cathode, it was also found necessary to employ streaming gas, admitted from below the cathode, and, in order to obtain details of the line structures, to sacrifice field strength to obtain a steady and bright source The scale of the resolution of the lines compared with the splitting of the lines of atomic hydrogen, appears clearly on a plate accompanying the paper

Structure of the Atomic Nucleus — Latimer, in the March number of the *Journal of the American Chemical Society*, points out that the abundance curve for lighter elements, the atomic weights of which are approximately integral multiples of four, shows maxima for 4, 7, 10 12 and 14 alpha particles, which suggests that the alpha particles are arranged in a tetrahedral pattern He proposes an arrangement of 4 alpha particles in a tetrahedron with a certain coupling of proton spins and, by continuing the

pattern to 10 alpha particles, finds a point in the lattice about which four protons converge in the same manner as in the alpha particle. The entrance of a pair of electrons at this point explains the first pair of extra electrons found in argon (40), and an extension of the principle appears to give a complete explanation of the numbers of extra electrons required in the heavier elements. With the addition of the extra electrons, the proposed nuclear structure becomes a diamond shaped lattice of electron pairs joined by protons. The model may be interpreted as the pattern determined by the directions of the proton spin vectors, the angle between any two proton vectors being that formed by lines from two corners of a tetrahedron to its centre. This is the angle at which two elementary spin vectors add to give a resultant of two units. The quantity $\frac{1}{2}\sqrt{n(n+2)}$ is the magnitude of the vector representing n units of spin, and only resultants with integral values of n are permitted. The geometry of the tetrahedron is thus clearly seen to be that demanded by quantum mechanics for the combination of two unit spin vectors. The paper is illustrated by representations of models, which add considerably to the clearness of the ideas put forward in it.

Atomic Weight of Iodine.—In an investigation of Baxter and Tilley in 1909, the ratio of silver to iodine pentoxide was found to be 0·646225, whereas the values Ag = 107·880 and I = 126·932 give 0·646251 (isotopic oxygen mixture = 16·000). It is now shown by Baxter and Butler in the March number of the *Journal of the American Chemical Society* that the ratio Ag/I_2O_5 is affected by two sources of error: (1) the adsorption of air by very porous iodine pentoxide, and (2) the fact that iodine pentoxide produced by the dehydration of iodic acid appears to contain less iodine and more oxygen than corresponds to the formula I_2O_5. Whilst the modern value for the atomic weight of iodine rests on several well-established ratios to silver and to the other halogens, it would be necessary in order to reconcile the experimental values of the ratios of silver and iodine to iodine pentoxide with the theoretical values to increase the atomic weight of iodine by 0·005 unit in the former case and decrease it by 0·03 unit in the latter. Great care was taken in the purification of the iodine pentoxide, which was then decomposed by heating at about 400° in a weighed quartz reaction vessel which contained hot silver to prevent escape of iodine, and finally the weight of the iodine was determined. Water retained by the pentoxide was collected in a weighed absorption tube and correction of 0·001 per cent for adsorbed air was made. The ratios I/O and I_2/I_2O_5 were found to be 3·17262 and 0·760342, which would correspond with I = 126·905, which is considered to indicate an excess of oxygen of 0·005 per cent in the pentoxide above the theoretical value. Iodine pentoxide of normal composition has not been prepared.

Hydrogen Ion Concentration in Unbuffered Solutions.—A platinised electrode in a hydrogen atmosphere adsorbs the cation or base from a salt or base solution, thus yielding a more acid solution in the cell than before treatment with hydrogen. This forms a serious objection to the use of the ordinary type of platinised platinum electrode in unbuffered solutions. Again, since acid base indicators are weak acids or bases, large errors may be caused in their use in measuring the pH of pure water or extremely dilute solutions of acids or bases. These problems are discussed in three papers in the March number of the *Journal of the American Chemical Society* by Kolthoff and Kameda. In the first, it is shown that acid adsorbed by platinum can be removed by washing with water in a hydrogen atmosphere. An electrode coated with a bright layer of platinum was used, which gave satisfactory results in unbuffered or slightly buffered solutions. The electrode after platinisation, is treated with hydrogen bubbled through water, and the cell then washed out and solution admitted. The electrodes are easily poisoned and are replated after each set of measurements. In the second paper the use of mixtures of two forms of an indicator in different ratios is described, the indicator being isohydric with the solution. The colour in the unbuffered solution is compared with that in an ordinary buffer solution with the same indicator mixture, a correction for the difference of ionic strength of the two solutions being applied. In the third paper, the hydrolysis of zinc sulphate solutions was investigated. The second paper emphasises the importance of using pure indicators, the commercial products not always being satisfactory in this respect.

Corrosion of Copper.—The green patina produced on copper by more or less prolonged exposure to moist air is generally stated to be a basic carbonate. In two papers in the *Journal of the Institute of Metals*, (vol 42, p 181, 1929; vol 44, p 389, 1931), Vernon and Whitby have reported analyses of the deposit formed in different localities in England, and these show that in the particular samples examined the main constituent is a basic sulphate of copper, with very little carbonate. In some specimens from coastal towns there was chloride; in specimens from Lowestoft there was a considerable amount. In only one specimen was there no carbonate. London samples contained copper sulphide, sometimes to the extent of more than 10 per cent, and the action of hydrogen sulphide is considered to play an important part in the corrosion. In the second paper, it is shown that the compositions of the materials of the patina more than seventy years old correspond with the natural minerals brochantite $CuSO_4 \cdot 3Cu(OH)_2$, atacamite $CuCl_2 \cdot 3Cu(OH)_2$ and malachite, $CuCO_3 \cdot Cu(OH)_2$. There is an interesting general discussion at the end of the second paper.

Solid Polyiodides of Potassium.—Although solid polyiodides of cæsium, rubidium and ammonium have been shown definitely to exist at ordinary temperatures, whilst no solid polyiodides of sodium and lithium are reported, the solid polyiodides of potassium have been the object of several researches which have led to conflicting conclusions. Up to the present, four investigators have considered that they have prepared KI_3, although only one reports analyses supporting his results, whilst two have obtained evidence for its existence. At least four investigators have failed to obtain it, or have given evidence against its existence. There is a similar conflict of evidence in the case of KI_7. In the March number of the *Journal of the Chemical Society*, N. S. Grace has shown that the solid polyiodides obtained from aqueous solutions contain water of crystallisation, the two compounds $KI_3 \cdot H_2O$ and $KI_7 \cdot H_2O$, stable at 25°, being isolated. Previous work of Abegg and Hamburger which had been interpreted as indicating the existence of KI_7 is shown to be substantially accurate, but the polyiodide was shown to contain two molecules of combined benzene $KI_7, 2C_6H_6$. Evidence is given that no unsolvated polyiodides of potassium exist at 25°. Results of Parsons and Whitmore, which have been regarded as disproving the existence of solid polyiodides, are shown to be too incomplete to provide any such evidence.

Agricultural Science in Palestine

WHEN the Zionist organisation began to develop its programme for the colonisation of Palestine, it realised the need for scientific research into agriculture and horticulture and set up an experimental station at Tel Aviv under the directorship first of Dr Warburg, and now of Dr Elazari Volcani Laboratories were equipped and arrangements made for field experiments in the various parts of the country being colonised under Zionist auspices As might be expected, the scientific work has been well done and a number of interesting results have already accrued, opening up many possibilities for the future The Zionists are not the only Jewish investigators in Palestine the French organisation, known as P I C A, has its school and experimental farm at Mikveh, where good work is done, and there is, of course, the Palestinian Government Department with its headquarters at Jerusalem

The agricultural problems are those of a dry region of smallholders—a usual type of holding where irrigation can be widely practised but less common otherwise The smallholdings are necessitated by the circumstance that Palestine is only a small country, already carrying a considerable population of Arabs who have been there for many years and regard themselves as having a good claim to the land, while the number of Jews who wish to colonise it is considerable To meet the difficulty, the method was early adopted of working out schemes of husbandry suitable for small farmers of intelligence but not much capital In the Plain of Sharon, the best prospects are for fruit, flowers for scent, and, near the towns, dairy products and vegetables In the Emek these are less suitable though dairying is being seriously attempted the simple obvious products are cereals but these are not easy to sell profitably

The Tel Aviv work is based on a sufficiently comprehensive programme and it covers practically all subjects bearing upon the colonists' problems Throughout the purpose is to intensify agriculture in order to provide a higher standard of living for a larger rural population This involves the more intensive production of existing crops, the introduction of new ones, and the improvement of the native breeds of live stock At the same time, the Division of Rural Economics is making a careful survey of the conditions of production of the existing crops and live stock products with the view of further development Possibilities of disposal of the increased output are being explored the home market is not particularly large, but Egypt and the near parts of Europe offer some prospects for an export trade

Dairy farming, in particular seems to offer many advantages It gives a higher output per man and per acre than the traditional agriculture, and thus lends itself to a denser agricultural settlement The resulting animal manure raises the fertility of the soil for other systems of farming The investigation has been assisted by the Empire Marketing Board, which arranged that Mr J Crichton of the Rowett Institute, should study the subject on the spot The technical problems are well on the way to solution The grading up of the dairy cattle has been started, and also the initial improvement of the soil to a point at which it will begin to carry the new system, and the elaboration of a suitable cropping scheme The Palestinian demand for dairy produce being insufficient, it is proposed to build up a control organisation strong enough to maintain such a standard of quality as will secure the products in the overseas markets [1] The possibility of the development of a sugar industry is being examined [2] The most hopeful solution appears to be the combined cultivation of cane and beet, thus spreading the work at the factory over a longer season and broadening the scheme of cropping Sugar cane, although little grown, is not a new crop in Palestine Beet, however, presents certain difficulties in the dry regions, but these can be overcome by irrigation at critical periods

Among the indigenous plants are eight species of wild flax, and the growing of flax for seed, carried out in Bible days, is being exploited once more So far no serious diseases or pests have affected this crop, though it is anticipated that dodder is likely to put in an appearance at some future date

Palestine, however is always liable to plant diseases and pests, and steps were taken from the outset to cope with them Dr Reichert, who is in charge of the Division of Plant Pathology, and is ably assisted by Miss Hellinger, has confined his attention principally to the banana, citrus, and wheat crops 'Internal decline', a physiological disease of citrus fruits well known in other regions, has now been recorded in Palestine Diplodia stem end rot is widespread, and in 1929 cost the Palestine orange industry some £25,000 It is, however practically eliminated by debuttoning the fruit by colouring it A third trouble, due to *Sclerotinia sclerotiorum*, is common to citrus, banana, and various other crops The banana is particularly susceptible and there seems considerable danger of the spread of the fungus thence to the citrus groves The wheat studies, commenced in 1923 and still in progress, have been chiefly concerned with the relative susceptibility of different varieties to bunt, and it is of considerable interest that the wild emmer (*Triticum dicoccoides*) has been found to be highly susceptible

Dr Oppenheim, of the Division of Horticultural Breeding, is working principally upon the sugar content and the acidity of the orange fruit during its development, and upon breeding methods for improving the citrus crop He emphasises the importance of bud selection and suggests the establishment of a national organisation for the selection of stock and of bud wood from trees already existing in the groves

Of the insects giving trouble to the grower, locusts are the best known, and the Government has set up a good locust service to observe and deal with the insects as soon as they appear Other insects, however, are also harmful Dr F S Bodenheimer, in his bulletin on the Coccida or scale insects of Palestine, enumerates some 65 species, of which eight are new to science Even this list by no means exhausts the Coccid fauna and he has since issued supplementary notes He has studied also the Wood Leopard moth (*Zeuzera pyrina*), an insect which causes great damage, particularly to olive and apple trees, by its larva tunnelling in the wood The use of paradichlorbenzine or calcium cyanide is recommended as a remedy easy to handle and to apply Among other entomological papers, the report by H Haupt on *Homoptera Palestinæ* I [3] and that of F S Bodenheimer on tobacco pests may be mentioned Some of the latter originally affected wild Solanaceæ and other plants, but are now passing over to the newly planted tobacco and cause considerable injury

Spraying naturally comes in for a good deal of study one interesting paper deserves mention [4] Assuming varied standards of mortality by spraying, and a 95 per cent natural mortality in each generation of the larvæ from the eggs surviving spraying, it is shown that insects with 10 or 20 eggs per female cannot maintain their existence under such control measures, but that the Red Scale (*Chrysomphalus*

aurantii), which has 100 eggs per female, can only be controlled by a spray giving at least 90 per cent mortality, and that one, or at most two, sprayings per year are then sufficient The control measures should be applied at the time of population minimum, the numbers cannot be materially reduced if dealt with at the time of population maximum Similar considerations are applied to field mice control

The publications of the Tel Aviv Institute are not confined to agriculture and horticulture A systematic survey of the flora of Palestine is now being carried out by A Eig Two bulletins on the systematic side and one from the ecological aspect give an excellent bird's eye view of the flora of Palestine The flora is in process of active transformation owing to the effect of modern methods of land cultivation Marsh species are tending to disappear owing to increased drainage, while certain dry land species are vanishing with the spread of irrigation

The attempt to fix the shifting sand dunes will probably affect the dune flora These imminent changes render it desirable for the botanical surveys to be pushed forward as rapidly as possible but the work is handicapped by the fact that most plants are short lived appearing in the spring only so that only relatively small areas can be investigated each year The flora is much affected by physical factors especially by the distribution of rainfall, as the period of greatest heat synchronises with that of absence of rain Steps are already being taken to preserve the native flora, to guard the reserves, and to plant woods of forest trees

One of the publications makes an especially wide appeal Dr Volcani's pamphlet, "The Fellah's Farm", which, apart from its special agricultural matter, is of general interest because of its many references to survivals of ancient Jewish and fellah folklore Here for example, is a summary of the rites still performed by the local peasantry when the rain has failed to appear

"Each district has its local rites There may be a procession of girls in the twilight after the evening meal, beating empty petrol tins containing pebbles, in order to make even more noise They knock at the doors of the houses, and are sprinkled with water An old woman marches before them, a handmill on her head, on top of which a rooster shut in a basket crows lustily to call forth divine compassion A pitcher of water occasionally replaces the handmill A white cock and a black hen are carried along and beaten at intervals so that they may cry all the louder Grain and flour sifters are carried on the head to symbolise the famine threatening man and beast Sometimes an old woman, riding a donkey backwards and carrying an infant, grinds an empty handmill These figures are meant to personify innocence The old woman can no longer do wrong, while the infant has not yet tasted sin The rooster represents the domestic animals"

The workers at Tel Aviv, and the Zionist Organisation supporting them, are to be heartily congratulated on the volume and quality of the work they have already done under conditions which have sometimes been both difficult and trying With the setting up of the new experimental field at Rehovat, we may expect an even more extensive study of Palestinian problems A good beginning has been made we wish the workers all success

The Satellites of Jupiter

PROF DE SITTER, Director of Leyden Observatory, delivered the George Darwin Lecture of the Royal Astronomical Society on May 8, taking as his subject "The Satellites of Jupiter" The lecture began with a sketch of the progress of our knowledge of the system Galileo attempted to make tables of their motion Romer deduced from them the finite velocity of light Wargentin devoted a large part of his life to the study of their motions Bradley made careful observations La Grange improved the mathematical theory Delambre and Damoiseau made tables, which remained in use until recent times Forty years ago, Sir David Gill carried out a series of observations with the Cape heliometer, he compared the satellites with each other, not with Jupiter itself, finding that this increased the accuracy of observation very notably The positions of certain stars had been found with great accuracy in connexion with the determination of the solar parallax from observations of the planets Iris, Victoria, and Sappho These stars were now used to check the scale of the heliometer, and this was considered to be known to one part in 100,000 Prof de Sitter took a large part in reducing these observations, he found from a combination of all determinations that the mass of the Jovian system is 1/1047 40 of the sun, with a probable error of 0 03 in the denominator

Prof de Sitter then gave an outline of the different classes of perturbations, which he divided into four groups (1) Those with periods of less than 17 days, (2) periods of 400 500 days, (3) the small libration of satellites I, II, III about their equilibrium position—he found that the period of this is close to six years, (4) those exceeding Jupiter's period of revolution The inequalities of short period exceed in magnitude the oscillations arising from the eccentricities of the orbits, he therefore used intermediary orbits based on these inequalities, instead of using ellipses

The values given by Prof de Sitter of the masses of I, II, III, IV were 381, 248, 817, and 509, expressed in units of the seventh decimal of Jupiter's mass Those of II and III are the best known the different determinations of these being very accordant He made a comparison between the Jovian system and (1) the four interior planets, (2) the four giant planets He noted that 33 years in the satellites corresponded to 17 centuries in the terrestrial planets and to 1200 centuries in the outer planets Consequently, progressive changes take place much more rapidly in the satellite system, which adds interest to the study of them

Prof de Sitter also alluded to his studies of the variations in the rate of the earth's rotation as shown by the fluctuations in the motions of the moon, the inner planets, and Jupiter's satellites Certain discrepancies between the results from Jupiter's satellites and those from the other sources suggest the possibility that the Jovian system might have fluctuations of its own He showed from a diagram that the fluctuations were small during the nineteenth century, so that it was not until the present century that their reality could be affirmed with some confidence

Newcomb had, however, suggested many years before the possibility that the lunar fluctuation might arise from changes in the earth's rate of rotation

Prof de Sitter stated that his work had been assisted by excellent series of photographs of the satellites obtained at many observatories He made a comparison between the accuracy of heliometer and photographic positions the probable error of one position with the former was 0 075″ while that from a plate with six images, measured in two positions, was 0 02″ 0 03″

Weather and Health

AN interesting report, prepared by Dr Ellsworth Huntington with the advice of a strong committee based on the daily meteorological and mortality records of the city of New York from April 15, 1882, to Mar 24 1888 appears as *Bulletin* No 75 of the National Research Council (National Academy of Sciences, Washington) Gross mortalities at ages under five years and over five years are considered separately also mortalities in these age periods from causes other than pneumonia and influenza Mortality from pneumonia and influenza (all ages) forms a separate group The data are expressed as percentages of the daily average of the particular year, and when necessary, corrections for seasonal trend are introduced For sufficient reasons, graphical methods are chiefly used, in particular climographs that is a third variable daily deaths is shown by contour lines on a bivariate diagram for example, of temperature and relative humidity It is contended that the method leads to clearer results than the use of correlation coefficients and massed averages

The principal conclusions reached are these Judging by the data of deaths from all causes except pneumonia and influenza among persons over five years of age the optimum temperature is close to 65° F Among children under five years the optimum is about 10 lower Among extremely young infants however, there is evidence that the optimum is higher So far as influenza and pneumonia are concerned it appears that the chances of contracting the disease are at a maximum with the lowest and a minimum with the highest temperatures but that the chances of death after the disease has been acquired are subject to the influence of the normal temperature optimum It appears that at the optimum temperatures, low atmospheric humidity is harmful but, among young children, plays only a minor part Above the optimum temperature, the best humidity appears to be progressively lower as the temperature rises

Much stress is put upon the relation between interdiurnal variability of temperature and mortality "No matter whether a drop of temperature causes the mean temperature to be better or worse, it tends to produce a stimulating effect which induces a relatively low death rate both on the day in question and the next day In similar fashion, no matter whether a rise of temperature brings a favourable or unfavourable mean temperature, its effect for two days is to raise the death rate" Still more interesting is the apparent fact that a moderately high degree of variability of temperature from day to day is more favourable than low variability In this respect there is a similarity between the experience of New York and of Stockholm, which suggests that there is a definite optimum variability independent of temperature

The author asks whether "the apparent difference from season to season" may not "merely represent the fact that in cold weather we are protected from changes of temperature" He finds that ideal weather in New York would be characterised by an average temperature of about 65° and a relative humidity of nearly 90 per cent The preceding ten days should have been characterised by fairly strong changes of temperature, averaging 4°, and should culminate in a fall of 10° or 12° It seems that south east England, outside the smoke laden area of London, approaches as near to the ideal as we may hope to come but the author points out that many other variables remain to be considered

University and Educational Intelligence

CAMBRIDGE —The Sadleirian professorship of pure mathematics will be vacant on Sept 30, 1931, by the resignation of Dr E W Hobson

The Appointments Committee of the faculty of mathematics has reappointed Mr S W P Steen, of Christ's College, and Mr T G Room, of St John's College to be University lecturers in the faculty, and Mr E C Bullard, of Clare College, to be University demonstrator in geodesy

A report has been received from the managers on the regulations for the Quick professorship of biology In October Prof G H F Nuttall retires from the chair after having held it for twenty five years By the terms of Mr Quick's will, the benefaction must always be used to promote 'study and research in the sciences of vegetable and animal biology" Authority is given to the managers however, to propose to the University changes in the particular field of biology with which the chair shall be associated From 1906 until 1919 this field was defined as protozoology in 1919 parasitology replaced protozoology The managers now recommend to the University that the next tenure of the Quick professorship should be associated with the field of research which they define as the study of the 'Biology of the Cell" If this recommendation is approved, they intend to offer the chair to Mr D Keilin, who has for some years been carrying on research work of this type in the Molteno Institute

The University has conferred the honorary degree of M A on Mr E Everett on his retirement, after more than forty years service from the post of assistant to Sir J J Thomson at the Cavendish Laboratory

DURHAM - The Council of Armstrong College has appointed Dr E G Richardson to be lecturer in physics Dr Richardson is at present lecturer in physics at University College London, and is engaged on research in connexion with the propagation of high frequency radiation in gases

LONDON —The London School of Economics and Political Science has been granted the sum of £142,000 by the Rockefeller Foundation This sum has been allocated as follows £60 000 for reconstructing and extending the library, £10,000 for the purchase of additional books, £30,000 towards the purchase of land for new school buildings, and £42,000, in annual grants of £6000, for providing increased facilities for post graduate teaching and research

The late Mr Clifford B Edgar has bequeathed £4000 to the London School of Hygiene and Tropical Medicine for the promotion of research Mr Edgar was a graduate of the University, and intimately connected with its work for many years, having acted as chairman of the Finance Committee from 1910 until 1920

The Court of Common Council has renewed for 1931

its grant of £105 in aid of the University's extension work, and the Drapers' Company has renewed for the year 1932 its grant of £500 for the Department of Applied Statistics at University College The Civil Service Commission has notified the University of the renewal for 1931–32 of the present subvention of £2250 from Indian revenues towards the cost of probationary instruction of selected candidates for the Indian Civil Service

OXFORD At Rhodes House, on May 9, Prof A Einstein delivered in German the first of his three Rhodes Lectures on ' The Theory of Relativity—its Formal Content and Present Problems " He gave a general exposition of the special and general theories of relativity, emphasising the need of ' logically satisfying " assumptions and explaining the methods of advance from the Euclidean to a pseudo Euclidean metric and hence to the Riemann metric The general theory could not, however, provide a logical explanation of the electromagnetic field In his second lecture, on May 16, Prof Einstein will discuss the problem of the finite universe In his last lecture, on May 23, he proposes to give an account of his attempt to derive both the gravitational and electromagnetic fields by the introduction of a directional spatial structure

— —

THE following courses of free public lectures in metallurgy have been arranged by the Armourers and Brasiers' Company —At 8 o'clock on May 21 and 28 and June 4, at the Royal School of Mines, 'Thin Films on Metals', by U R Evans, and at 5 30 on May 27 and June 3 and 10, at King's College, Strand, 'Some Impurities in Metals and the Production of Metals of High Purity ', by Dr W Rosenhain No tickets are required

Birthdays and Research Centres

May 18, 1873 —Dr H ELTRINGHAM, F R S president of the Entomological Society of London (1931)

Is more or less continuously engaged in the histological structure of insects, more especially that of special glands and organs At present investigating the structure of the abdominal organs in the smaller caddis flies, the action of 'diaphanol' on chitinous and other structures, and the structure of the eye in Aleurodes

At all times prepared to undertake histological investigations into the finer structure of insects, and should be glad to have unusual material for this purpose from anyone who has the opportunity of obtaining same in a proper state of preservation Would be glad to furnish suitable preservative fluids to any one who can obtain material suitable for investigations of this character

May 19, 1876 —Prof W K GREGORY, curator of the Department of Ichthyology, American Museum of Natural History

My chief investigation now in progress is the study of the skulls of fish of many orders and families Each skull is considered from two points of view first, as a natural mechanism (the inert part of a machine that serves in the complex turnover of energy taken in and paid out by the organism as a whole), secondly, as a morphological pattern, which has acquired its various characters at different stages of its phylogenetic history

I should welcome researches bearing upon the hypotheses that triradiate sutures arise through the equal growth away from each other of three centres of ossification and that the semicircular canals arose in a similar manner A functional analysis of parts of the neurocranium (cranial vault, interorbital bridge, ethmo vomer block keel bone or parasphenoid) leads to interesting results

May 23, 1850 — Dr G C DRUCE, F R S, Fielding curator in the University of Oxford

I am at present engaged in an investigation of the flora of Cyprus

May 23, 1864 —Sir ARTHUR SMITH WOODWARD, F R S, lately Keeper of the Department of Geology, British Museum (Natural History)

I have accumulated many fossil fishes on which I hope soon to continue research but I have been occupied for a long time in preparing (and largely re writing) a second English edition of Zittel's 'Palæontology ', vol 2 (Fishes, Amphibians, Reptiles, and Birds) which is now in type and nearly completed A new edition of my Outlines of Vertebrate Palæontology " will probably follow I think that one who has had long experience of any sphere of research can do good service to science by attempting, from time to time, to digest and correlate the results of the multitude of technical papers and memoirs which now appear in more rapid succession than ever

Societies and Academies

LONDON

Royal Society, April 30[1] – **J A Todd** On twisted cubic curves which satisfy twelve conditions The paper deals with the problem of determining the number of twisted cubic curves in space which satisfy the joint condition of meeting r lines in one point s lines in two points, and of passing through t fixed points where $r+s+2t=12$, so that the condition determines a finite number of curves The simpler cases are treated by a variety of elementary methods, for the more complicated cases the principle of special position is employed in which the given lines and points are made to assume particular positions in such a manner that the curves which are required fall into various classes of which the number of curves in each is determined by simpler considerations — **H T Flint** A metrical theory and its relation to the charges and masses of the electron and proton This paper points out the analogy existing between the equations of the quantum theory and the electromagnetic equations of Maxwell, pointing to the existence of a definite natural metric in a five dimensional continuum Parallel displacements along the world lines in this continuum are associated with no change in length but in the four dimensional world the change of length is a periodic function with a frequency proportional to the mass associated with the world line This view leads at once to the interpretation of the ratio of the masses of the electron proton as a metrical ratio, and makes a unitary physical theory possible —**A M Mosharrafa** Material and radiational waves The Maxwellian equations of electromagnetic and electron theory are derived from one set of basic relations in a manner which throws some light on the relationship between material and radiational waves, and accounts for the existence of exactly three types of physical entities, namely positive electricity negative electricity, and radiation It is shown that a physical entity may be associated with the propagation of a vector A in a direction n If A and n are in the same direction, the entity is recognised

[1] Continued from p 726

as positive electricity, if in opposite directions as negative electricity, and if mutually perpendicular, then as radiation In the general case, A will have both a longitudinal and a transverse component, corresponding to the co existence of matter and radiation — **J Guild** The colorimetric properties of the spectrum The paper describes an investigation carried out at the National Physical Laboratory to determine the colorimetric properties of a group of seven subjects as obtained from direct measurements of the trichromatic coefficients of the spectrum on a trichromatic colorimeter A proposal is made for the adoption of a set of standard data, to represent a normal eye for technical colorimetric purposes, based on the results of this investigation and those recently published by W D Wright —**C Robinson** and **H A T Mills** The colloid chemistry of dyes The aqueous solutions of benzopurpurine $4B$ and its isomer prepared from m tolidine (1, 2) Although benzopurpurine $4B$ is a well known cotton substantive dye, its isomer prepared from m tolidine has not sufficient affinity for cotton for it to be of practical use as a dye stuff An investigation of the solutions of these dye stuffs has been carried out in order to see if correspondingly great differences could be found in their colloidal properties The viscosity of their solutions (if not super saturated) are the same and are of the order to be expected in an unhydrated colloid The viscosity does not vary with rate of shear, and the conductivities are of the same order On the other hand, ultra filtration, flocculation by electrolytes, and ultra microscopic examination show marked differences between the two dyes which may be explained if it is assumed that benzopurpurine $4B$ forms larger aggregates than the meta isomer The osmotic pressures of the two dyes are almost the same, this can be accounted for in spite of the difference in particle size shown by experiments described It is concluded that these dyes exist in solution as totally dissociated colloidal electrolytes, hydrolysis being negligible —**G B Deodhar** X ray nondiagram lines In the K and L series, nondiagram lines pairs are found which show approximately constant $\sqrt{\nu/R}$ differences These seem to resemble the usual screening doublets —**T E Stern** The chemical constant of chlorine vapour and the entropy of crystalline chlorine By statistical mechanics the molecular composition of chlorine gas is calculated, assuming that the ratio between the numbers of atoms of the two isotopes 35 and 37 is known It is found in this calculation that the angular momenta of nuclei are without effect upon the constitution of chlorine gas The vapour pressure of chlorine crystals is also calculated and, finally, the entropy of chlorine per mole in the crystalline form at the absolute zero **I E Knaggs** The molecular symmetry of hexa amminobenzene in the crystalline state and certain other properties of the substance An examination of crystals of hexa aminobenzene by the powder X ray photographic method has shown the crystal symmetry to be that of the holohedral cubic class, the space group being O_h^2 There are 16 molecules in the unit cell of side 15 14 A, and the molecules possess a threefold axis of symmetry —**H W Melville** and **E B Ludlam** The effect of foreign gases on the lower critical oxidation limit of phosphorus vapour The experiments were carried out to test the equation originally proposed by Semenoff In the present approximate state of the theory, the differences obtained are explained on the variation of the diffusion coefficient of the chain propagators into the foreign gas The results show no correlation with those obtained for foreign gases at the upper critical oxidation limit —**L Rosenhead** The lift on a flat plate between parallel walls The effect of the walls is to increase the lift-coefficient, and curves and tables are given showing this increase for various values of the angle of attack and the ratio of chord of aerofoil to width of channel —**J A V Butler** and **A D Lees** The behaviour of electrolytes in mixed solvents (3) The molecular refractivities and partial molar volumes of lithium chloride have been determined in a series of mixed water alcohol solvents It is found that the molecular refractivity is constant in each solvent over the range of concentrations investigated Its value is scarcely affected by the presence of alcohol until the molar fraction of the latter is more than 20 per cent, and then falls off steadily to the value for pure alcohol The effect of lithium chloride on the density of the solutions varies greatly with the composition of the solvent —**T C Marwick** An X ray study of mannitol, dulcitol, and mannose The relationship is traced between the structures of mannitol and dulcitol, and between the structures of mannose and other saccharides (See also NATURE, Jan 3, 1931, p 11)—**G I Finch** and **J C Stimpson** The electrical condition of hot surfaces during the adsorption of gases The electrical conditions of a carbon rod and a copper sheet have been studied at temperatures up to 850° C *in vacuo*, and in contact with various gases The results of these experiments suggest that 'normalisation' of the carbon involves the evolution of occluded gases accompanied by structural changes in the surface, but that in the case of copper it involves a process of sintering —**A B D Cassie** and **C R Bailey** Investigations in the infra red region of the spectrum (3, 4) The absorption spectrum of carbon disulphide is described between the limits of 1 μ and 22 μ, and the results compared with those of Coblentz for the liquid The molecule possesses a rectilinear structure, with probably a single linkage between the carbon and sulphur atoms The Raman spectrum has been co ordinated with the infra red spectrum, and an explanation is offered for the appearance in both of the characteristic doublet associated with the inactive frequency —**D R M'Rae** Asymmetry observed in the stark component of H_α A special grating having a very intense first order spectrum on one side has been used to resolve the Stark components of H_α Asymmetry is observed in the displacements of the components, and also in the relative intensities of the components Altering the number of atoms in the initial states does not explain completely the asymmetry of intensities —**F D Miles** The apparent hemihedrism of crystals of lead chloride and some other salts Lead chloride, which normally shows holohedral orthorhombic symmetry, can, under certain specified conditions, be obtained from hot solutions containing dextrine in microscopic crystals consisting of a single form (a bisphenoid), which can have only axial symmetry By reducing the concentration of dextrine this form can be gradually repressed Normal crystals of lead chloride were grown and investigated by X ray methods The difficulty of X ray work with crystals impervious to the radiation is emphasised, and a simple method is given for finding whether any given reflection will emerge from any crystal face The structure contains two glide planes of symmetry The symmetry is, therefore, in all probability holohedral The idea that crystal faces lying opposite to each other across a plane of symmetry may behave differently to an optically active reagent is supported The cases described appear to be the first to demonstrate that the presence of optically active material may induce the *growth* of a hemihedral crystal of a substance, the normal symmetry of which is certainly higher —**C E Wynn-Williams** The use of thyratrons for high speed automatic counting of physical phenomena The thyratron may be regarded as a triode valve which

contains a trace of mercury vapour or inert gas at low pressure Under appropriate conditions, a positive voltage impulse of only a few micro seconds' duration applied to the grid will cause an arc to strike between the anode and cathode (or filament) The arc then continues independently of further grid potential changes until the anode circuit is momentarily inter rupted In this respect the thyratron behaves as a very delicate, inertialess relay, capable of controlling considerable currents Some circuits are described for utilising to the greatest advantage the 'inertia less relay' characteristic of the thyratron, for high speed automatic counting of voltage impulses set up by physical phenomena Two impulses separated by as little as 1/500th second can be separately recorded

PARIS

Academy of Sciences, Mar 30—**Camille Matignon** Some properties of commercial calcium nitrates These have been regarded by some people as liable to spontaneous combustion, and some insurance companies have enforced special premiums on this account It is shown experimentally that these views are erroneous—**Gabriel Bertrand** and **V Ciurea** Tin in the animal organism Previous work on this sub ject is criticised on the ground that the method em ployed did not differentiate tin from silica The authors, using a more exact method have found in the organs of the ox, horse, and sheep quantities of tin varying between 0 4 and 26 parts per million, the largest proportions being found in the tongue no tin was found in the peritoneum—**André Blondel** The limitations of photometry—**Léon Guillet** and **Jean Cournot** Remarks relating to the influence of occluded gases on the mechanical properties of metal lurgical products Criticisms of the conclusions of Guichard, Clausmann, Billon, and Lanthony on the effect of occluded gases on the hardness of electrolytic iron—**D Wolkowitsch** The representation of the results of a series of experiments by an approximate formula with two parameters—**Paul Delens** Con gruences of curves and figuration of invariants—**D Pompeiu** The property of holomorph functions—**A Magnan** and **A Sainte-Laguë** The distribution of aerodynamic velocities round an aeroplane in flight—**L Joly** A method of measuring the heat conduc tivity coefficient of materials—**Guy Emschwiller** The chemical action of ultra violet light on the alkyl iodides From a study of the action of ultra violet light on liquid alkyl iodides, it is concluded that the primary action is removal of a molecule of hydrogen iodide, this can react with another molecule of the iodide, giving a saturated hydrocarbon and iodine The other secondary products found can also be ex plained on this hypothesis—**Ch Bedel** The electri cal resistance of silicon It has been found possible to secure good electrical contacts with pure silicon, and obtain consistent figures The presence of small proportions of iron in the silicon has a marked effect on the resistance—**R Gibrat** The optics of uniaxial heterogeneous structures—**H Le Breton** The age of the recent marine terraces of Xu Nghé in North Annam (French Indo China)—**D Chalonge** and **E Dubois** The distribution of ozone in the atmosphere From the study of absorption spectra it is concluded that ozone is distributed in the atmosphere in a much less discontinuous manner than has hitherto been supposed, there are appreciable quantities at relatively low altitudes—**Mme F Bayard-Duclaux** The elec trical conductivity of the air at Paris—**Pierre Lesne** Organic adaptation in xylophage insects of the family of the Bostrychidae Commensalism of Lyctoderma—**Mme Lucie Randoin** and **René Fabre** Comparative researches on the proportion of SH derivatives in striated muscle, liver, and blood in the normal rat, in the underfed rat, and in the rat deprived of the B vitamins—**J Lefèvre** and **A Auguet** The problem of the relationship between the heats of work and repose The solution and laws Why work is more economi cal at low temperatures—**Ch Hruska** Vaccination against anthrax with non attenuated virus Saponin is added to the virus and this is injected The local swelling is cured in 15-20 days, and the animal is re sistant to infection The mixture of the virus and saponin is unaltered after keeping for fifteen months

The Scientific Worker in State Service

THE not wholly admirable human instinct for individual self preservation has given to the technical expert in medicine and surgery an impressively high status in the community A corresponding instinct for communal self preservation has combined with still less admirable instincts to maintain a high status for the technical expert in the warlike arts It is significant of the haphazard organisation of the human community that these emergency experts concerned with the pathological processes of individual or political life should hold a status not generally accorded to those technical experts who devote their not inferior knowledge and skill to the daily non pathological processes of a modern civilisation

The British Science Guild has added to its considerable public services by publishing the report of a committee which has since 1927 been inquiring into the functions of the scientific and professional staffs in the Public Services and Industry from the point of view of efficient administration and national development * The report is perhaps necessarily restricted to conditions in Great Britain and to the special classes of scientific and professional staffs which might have been more closely described as physicist chemist and engineer classes There is no reference to the biologist whose claim to improved status has been conceded only in pathological emergency —the entomologist for example has climbed to power by the ladder of fear which served the warrior and the medicine man The restriction of the field of survey to particular professional classes does little harm but the most superficial knowledge of conditions in Germany and the United States suffices to suggest that the other restriction should be removed by extending the survey to these countries The Engineer who became a Bank Vice President is an American story with a moral for the British reader which might profitably be written by the Guild it is far more significant than the better known story of the engineer who became Federal President If no other assault on the British art of improvisation avails the fear motive will eventually be effective in widening the sphere of influence opened to the technical expert When pathological processes are sufficiently obviously established in the industrial organism the industrial pathologist will be given the wide powers which should have been his as a

* A Report on the Scientific and Professional Staffs in the Public Services and Industry Prepared by the Committee on the Position of the Technical Expert in the Public Services and Industry Pp vi + 62 (London British Science Guild 1931) 1s

directing physiologist, powers which are already accorded in the competing industries of other countries

The committee indicates its awareness of this international contrast in a single sentence "It can hardly be doubted that the contrast admittedly existing between the high *average* modernity of industrial plants in America, Germany, and France and the number of relatively obsolete plants in this country, is attributable in no small degree to the fact that British technicians in many undertakings have been denied the opportunity to influence policy to the same extent as in the countries mentioned"

The report surveys the position of the scientific and professional worker in the local government service, the Civil Service, the forces of the Crown, and in industry, not from the point of view of conditions of service as affecting the individual, but from that of efficiency in the services and in industry It is concluded that neither in industry nor in the public service are the requirements fulfilled, in every case, for close collaboration on the part of the scientist or the technologist, the financial adviser, and the administrative chief', nor for "the proper presentation of the various technical, financial, and other considerations involved in every problem, in such a manner that those ultimately responsible for making decisions may be put in a position to weigh the several considerations in their bearing upon questions of general policy" The local government services are regarded by the committee as making better use of their scientific and professional staffs than do the other organisations considered, the Civil Service, with few exceptions, is regarded as the least satisfactory part of the field surveyed

This criticism of the national services is opportune The provision for the very wide range of scientific and technical work now undertaken by the State has been subject to intense criticism and investigation throughout the last few years A subcommittee of the Committee of Civil Research was appointed, in 1926, "to consider the co ordination of research work carried on by or under the Government, to report whether any further measures should be taken to prevent overlapping, to increase economy and efficiency, and to promote the application of the results obtained" In a report published in 1928 this 'Ormsby-Gore sub-committee' discussed the scientific services of the Government from the point of view of function and organisation without including recommendations for their improvement That recommendations were made, although not published, may be inferred from the report for the year 1928-29 of the Committee of the Privy Council for Scientific and Industrial Research ("In due course the sub-committee recommended, amongst other things, that ")

The recent Treasury committee on the staffs of Government scientific establishments had before it an outline, submitted by the Institution of Professional Civil Servants, for the radical reorganisation of scientific public services That committee, however, stated in its report (1930) that "The respective functions of the establishments within our terms of reference have recently been set out in considerable detail in the Report of the Research Co ordination Sub Committee of the Committee of Civil Research and we have assumed the first part of our terms of reference to be an instruction, not to criticise and report on those functions, but to take note of them as the basis of our investigation into the conditions of service of the staffs employed The Association of Scientific Workers submitted a generally similar scheme of reorganisation in its evidence to the Royal Commission on the Civil Service, now sitting The Commission, in turn, has declared itself unwilling to add to its herculean labours by considering proposals involving substantial modifications of departmental structure

The British Science Guild's Committee finds that, "The evidence which has been obtained by us shows that, as a general rule, the position of the scientific and technical staffs in the Home Civil Service is most unsatisfactory, and that, in the interests of efficient administration and national development, drastic reforms are needed in the organisation of many of the civil departments of the Government In order that the scientific and technical staffs should exercise their function properly it is imperative that the position occupied by the Minister of a civil department should be altered to accord with present day requirements, and further, that the responsibilities of the scientific and technical staffs in relation to the Minister should be clearly and specifically prescribed The heads of the scientific and technical departments should, it is submitted, be colleagues of, and be equal in status with, the permanent heads of departments, and not subordinates under a secretariat or similar body" The committee then proceeds to make suggestions for modernisation of the system

It may be that this increasing body of constructive criticism is misdirected It may be that Sir Holberry Mensforth's advice is of greater weight It may be that "The thing to do with these men is to lock them up in a room and feed them through a pigeon hole, you must not let them loose in your

organisation" But sentence of solitary confinement should be passed only by a balanced, fully informed, and fully authoritative tribunal, the full-bottomed wig would certainly be, the black cap might be, more appropriate head-dress for the occasion than are the cap and bells donned by Sir Holberry Mensforth

It is to be regretted that the Ormsby-Gore recommendations, on which the scientific services of the State must be assumed to operate at the moment, have not been communicated to the scientific world at large, also that a relatively large amount of attention has been given and is being given to merely subsidiary questions of the labels and rewards attached to the conduct of the scientific work of the State Examination of these matters was urgently necessary, and the recommendations of the Carpenter Committee are valuable and most welcome contributions to economy and efficiency So long, however, as the major issue is shirked, so long as those responsible for the organisation of scientific work for the State fail to take the scientific world into their confidence, so long as full inquiry into the best methods for ensuring the most economical and effective conduct of the technical work of the State—without undue tenderness about departmental structure—is delayed, just so long will improvisation, sometimes inspired, continue to bear its meagre fruit

The Charm of the Alps

The High Alps a Natural History of Ice and Snow By Dr A E H Tutton Cheaper edition Pp xvi + 319 + 48 plates (London Kegan Paul and Co, Ltd, 1931) 10*s* 6*d* net

DR TUTTON'S book is written by a lover of mountains for those who desire to know more about the ice and snow which they meet on glacier expeditions, and about the nature and causes of the glaciers themselves The first part of the book contains a good popular description of the physics and chemistry of water, snow, and ice It leads naturally to a second part in which snow and ice are considered in the mass, as they occur upon high mountains This second part includes an excellent, and not too long, account of the development of the theory of glacier movement (and interesting information concerning recent variations in mass of the glaciers), and a chapter on glacier phenomena—moraines, crevasses, and lakes—all treated in a simple manner An account of scientific work upon Mont Blanc, and the story of the Mont Blanc observatories, which find place in the third part of the book, might perhaps have been more logically placed in the second part The story of the Mont Blanc observatories is of particular interest, as it is abstracted from an account written for the author by M Joseph Vallot himself shortly before his death A topographical description of the chief mountain groups of the Alps might perhaps more logically have been placed in the third part of the book than in the second, which concludes with a brief historical sketch of the conquest of the great alpine summits

Even if the reader had not already been warned by the profuse illustrations of mountain scenery (more than 150 in number, and to be criticised only on account of their small size—would that they had been larger!), he will find in the second part of the book that Dr Tutton's real interest and enthusiasm lie in mountain expeditions and, particularly, in the views of the mountains which they afford In this, Dr Tutton carries on an illustrious tradition It is curious how great has been the attraction of mountains for men of science both in Great Britain and abroad H B de Saussure's encouragement of the first ascent of Mont Blanc in 1786, and his own ascent in the following year, are well known, but before that ascent he had spent many summers wandering in almost unknown alpine valleys Of our own countrymen, Beaufoy (who climbed Mont Blanc a few days after Saussure) was a fellow of the Royal Society —as, of course, were Sir John Herschel (Breithorn, 1822) and J D Forbes In later times, one in every twenty of the first three hundred members of the Alpine Club was, or was to become, a fellow of the Royal Society

Forbes's 'Travels in the Alps' is as much a record of mountain exploration as of his observations of glacier movement It, and the "Tour of Mont Blanc" (1845), in which he republished the account of his expeditions, played a part in the development of mountaineering which is difficult to exaggerate When Hudson and Kennedy and their companions made the 'guideless' ascent of Mont Blanc from St Gervais, in 1855, they carried a map taken out of one or other of these books—and that ascent was the true commencement of modern mountaineering

Modern climbing has developed a technique which would scarcely be recognised by the pioneers, but Dr Tutton points out with truth the catholic nature of the attraction which mountains have for different men If the great ice faces and steep ridges which are climbed to day have their own strong attraction, that does not compete with

the equal attractions of a high glacier pass such as the Col du Géant, or of a walk along a valley path Scenery is, and must remain, one of the chief motives of a mountain walk—whether that be a high or a low one, and the author is right where he says that the best mountain views are often to be obtained from the middle heights

The third part of Dr Tutton's book is of value and much interest We have our Murrays and Baedekers on one hand and our climbing guide-books on the other, but here is something novel, and differing from both In it Dr Tutton gives us an account of some of his own expeditions framed as a sort of guide book of glacier passes The treatment is topographical, and he has so selected his material that all the expeditions are within the compass of a moderate walker, while none is dangerous In particular, he is careful to mention good view points, and to describe the views met in the course of the expeditions What is better still, he illustrates these with his own camera It is impossible not to understand and feel Dr Tutton's own enthusiasm for mountain scenery when reading this last part of his book, and the book may be recommended not only to those who have walked in the Alps and would like to know more about the glaciers which they have crossed, but also to those who have never been there and would like to know wherein the attraction consists

Those of us who have climbed in the Alps are often asked to do the impossible—to explain our motives There is only one reply—" Go and see for yourself " But how is it to be done? This book may perhaps solve the problem for some It is not difficult to select from it a series of expeditions which would comfortably fill a holiday and serve as an introduction to the regions above the snow line

Genius-Hunting

Genetic Studies of Genius Vol 3 *The Promise of Youth Follow up Studies of a Thousand Gifted Children* By Barbara Stoddard Burks, Dortha Williams Jensen, Lewis M Terman, assisted by Alice M Leahy, Helen Marshall, Melita H Oden Pp xiv + 508 (Stanford University, Cal Stanford University Press, London, Calcutta and Sydney George G Harrap and Co, Ltd, 1930) 21s net

IF we allow one developed 'genius' to 100,000 children born (which is a liberal allowance), what is the chance that in the 250,000 Californian children, corresponding to 2 5 adult geniuses, one of these will have been picked out in the five or six hundred gifted children now remaining out of those selected in 1921–22 by the fact of their intelligence quotients (*I Q*'s) being 140 or above? Supposing one such should occur, shall we be able to differentiate him from the remaining 500 gifted children by the surprising record of facts concerning these children accumulated by Prof Terman and his colleagues? We scarcely imagine that a Shakespeare, a Beethoven, or a Rembrandt would have been associated with a high intelligence quotient when six to eight years of age It would seem to us that a more fitting title for this work would be " An investigation as to whether the promise of childhood is fulfilled in adolescence and (supposing the investigation can be still carried on) in adult life "

After all, intelligence tests are highly correlated with examination tests—even if we admit them to be an advance—but examination tests have not been very successful in bringing into the lime-light undoubted genius The London County Council has to deal with something like a permanent stock of half a million children, and annually some 30,000 may be selected for secondary education, from these again, later on, a further selection is made for academic training This has been in progress for thirty or more years, and a sample of 'gifted' children far larger than the Californian has been followed up and trained Individuals of various degrees of real ability have been recorded and have obtained substantial positions in a number of professions But will anyone venture to assert that a real genius has been netted by these tests? Yet if the tests have been cruder than the Californian —which we leave others to settle—they have dealt with incomparably greater numbers

The age differences form one of the major difficulties of the whole of the present investigation The same tests cannot be satisfactorily applied to children and to adolescents This is well illustrated when our authors come to deal with the changes during six years in the intelligence quotient of the 'gifted' children We find only 38 boys and 34 girls re-tested, and when these are divided into four age groups, we find four out of the total eight groups have only 5 to 6 children in them Statistically such numbers are wholly inadequate if we desire to reach safe conclusions Our authors themselves write

" The age range of the subjects was so great that no test, whether of intelligence, achievement, or personality, was suitable to all Moreover, because

of the limitations of time and funds it was not possible in the case of most of the tests to give them to all of the subjects to whom they were applicable However, in each case, the number tested is large enough to give a fairly reliable sampling To find out how a group of a thousand gifted subjects compares with a norm group, it is not necessary to test all of the thousand By testing a random sample of one hundred to two hundred of the thousand, we learn almost exactly as much as if we had tested all " (p 9)

When we remember that the children were originally selected as gifted on the basis of a single individual test series, the Stanford-Binet, the reasoning cited above seems somewhat obscure If a thousand children agree in excess of intelligence by a particular test, it by no means follows that a sample of a hundred—and it is occasionally smaller —will fairly represent the thousand in a great variety of other characteristics of a markedly different nature

In fact, the diversity of ages, the diversity of races, the diversity of tests, and the diversity of characters discussed render the results difficult to interpret, and make it hard for the reader to find his path through the many answers to the many questions propounded to children, teachers, and parents on a variety of ' blanks '

It is, perhaps, idle when a vast task has been undertaken and is in part accomplished to suggest that it could have been better and more economic ally carried out otherwise, but it seems to the present reviewer that if 1200 children of the *same* age with $I\ Q$'s of 140 and upwards and the same number of children of the same age with $I\ Q$'s below 100 had been selected in 1921 and *both* series followed up, we should have known more eight years later than we actually do, when the control series has not been followed up These numbers would have allowed for wastage, and a comparison of even 800 of both series by the *same* intelligence test would have been most profitable and far more reliable than a test repeated on only 72 of the gifted child series Twenty years after the second testing, very little more than an examination of " Who's Who in America " would have indicated whether any of the ' gifted ' or of the mediocre children, as judged by public estimation, had reached marked distinction, to say nothing of attaining a claim to genius

The authors of this massive series of volumes set out with the object of ascertaining whether a high intelligence quotient in childhood was an indication of a possible future adult genius, and they saw a double method of approaching the solution of the problem (i) by following up ' gifted ' children, that is, those with a high $I\ Q$, and (ii) by studying the childhood of several thousand individuals considered to be geniuses, and allotting them $I\ Q$'s

The method adopted in the latter investigation seems to us now, as it did when vol *2* appeared, to be little short of perilous The details of the childhood of the great are in some cases ample, in others sparse But on the basis of these haphazardly recorded details, three judges (Prof Terman, Miss M A Merrill, and Miss C Cox, the extractor of the biographical data) have, on the basis of their knowledge of the characteristic doings and sayings of children of high $I\ Q$'s, attempted the converse problem and assessed the youthful intelligence quotients of the bearers of the earth's great names, and assigned to each of them an $I\ Q$ which is on the average upwards of 140—that of their gifted Californian children

" The most significant conclusion of the author [namely, Dr Catherine Cox, the compiler of vol 2] is that the extraordinary genius who achieves the highest eminence is also the gifted individual whom intelligence tests may discover in childhood The converse of this proposition is yet to be proved " (p 23)

This is the result of what we term the perilous process of assigning $I\ Q$'s to the childhood of the great The actual position of the writers is well brought out in the following words

' It seems *quite evident* * that while any person with an $I\ Q$ as high as 140 [in childhood] may have the sheer intelligence requisite for exceptional achievement [in adult life], only a very small proportion are likely to possess the total complex of mental and personal traits that cause an individual to become eminent If it were not that personality traits and other non intellectual aspects of endowment wield an enormous power to enhance or inhibit the individual's use of his intelligence, we might expect in ten or fifteen years from our thousand California gifted children such a crop of geniuses as has never before graced the population of a single State " (p 24)

There is no attempt in the present work to measure quantitatively these " personality traits and other non intellectual aspects of endowment " which enhance or inhibit the use of intelligence It is, perhaps, reasonable to assume such to exist, but it is pure hypothesis to assert that the youthful intelligence quotient is a measure of adult intellectual power, and that genius would be apparent but for these unmeasured and undetermined

* Italics the reviewer's

'personality traits' and 'non-intellectual aspects of endowment' If the object of 'following up' is to ascertain these inhibitions, then the wording should have refrained from dogma, until these traits had been discovered and measured

While many readers will be most interested in the chapter entitled 'Re tests of Intelligence", and particularly in the Summary' on pp 61 62, a word of warning seems to be called for While in the eight years the 'scores' of a number of children have changed considerably, sometimes up and sometimes down, we have no control series, and therefore no evidence of how in the far more extensive group of non gifted children (as judged by their *I Q*'s) individuals may have risen If one boy among 27 'gifted' children can rise 50 points in seven or eight years, is it not possible, nay, more than probable, that among the many thousands of 'non gifted' children in California one or more may rise even double this amount, and if that State is to produce a genius at all in the next twenty years, may he not have been a child with an *I Q* far below 140 when the 'gifted' children were sorted out?

Notwithstanding our doubts as to whether the £12,000 which the three volumes of this investigation have cost have been spent to the best advantage, we readily admit the great interest which every social investigator must take in the present volume, especially in the later chapters As a study of how far the promise of childhood will be fulfilled in adolescence there is a great deal to be learnt from the work, only we hold that it would have been wise to have kept the frequent discussions on genius out of it To approach the problem of genius statistically we must deal with a far more numerous population, spread over a much wider field than those of a few thousand Californian children If, against probability a world genius, a da Vinci, a Goethe, or a Bach, appears among these Californian 'gifted' children, it will be more a startling chance than any contribution to an understanding of the origin of genius This point seems to be almost admitted by the authors themselves (p 469), but if this be so, why have they chosen "Genetic Studies of Genius' for the title of their researches? Why have they mixed up, in almost every chapter, the problem of the origin of genius with that of the future achievement of bright children?

Lastly, may we add a word of criticism which may help the writers in succeeding volumes of this encyclopædic work? The treatment is largely statistical, but their statistical technique is often defective We may illustrate this by one example, that on pp 28-30, where the writers endeavour to find from their *I Q* ratings in 1921-22 and 1927-28 (on the basis of 54 cases!) the correlation between *I Q*'s in *general* at a given interval of time They have not published their correlation table, so that we ourselves cannot attempt to deal with it But as they appear to have mixed boys and girls with marked sexually differentiated means, the correlation will, anyhow determined, be largely spurious

In the next place, the authors state that it was impossible to use the product moment method owing to the bizarre form of the correlation table arising from the truncating of the general population by the selection of 'gifted' children Accordingly, they suggest three other methods (i) The 'tetrachoric' method Now, this is based on a normal distribution of the data, and could not possibly be applied to a truncated quadrant without replacing, which the authors have not done (but might have done), the three quadrants truncated (ii) By a theory as to the regression The means of the gifted children *alone* cannot possibly give, as the writers suppose the correlation coefficient in the *unselected general* population (iii) The deduction of the correlation from the standard deviation of the differences of the two ratings This, if accurately applied, should give exactly the same result as the product moment method which they have discarded at the outset Clearly the authors are unfamiliar with the fundamental formulæ for measuring the influence of selection on correlation We do not believe that much could be learnt by even treating the 27 boys and 27 girls independently, but if it is worth while attempting this, then surely it were better not to apply three erroneously adopted processes to heterogeneous material

The title of this encyclopædic social inquiry suggests that the writers originally meant to deal with *hereditary* genius There is little about inheritance in these volumes But with the first conclusion of their summary we are in whole-hearted agreement, for it coincides with much observation of our own

> Gifted children come predominantly from family stocks of decidedly superior intellectual endowment and slightly superior physical endowment' (p 472)

Perhaps we may hope that a future volume may be devoted to the quantitative development of this special topic We trust, if it be so, that the need for a control series will not be overlooked

KARL PEARSON

Photoelectric Cells

Photocells and their Application By Dr V K Zworykin and Dr E D Wilson Pp xi + 209 (New York John Wiley and Sons, Inc , London Chapman and Hall, Ltd , 1930) 12*s* 6*d* net

UNTIL recently, there was a serious lack of really representative books dealing with the theory and practice of the photoelectric and selenium cells Happily, this no longer exists, thanks to Dr Campbell and Miss Ritchie—whose exhaustive book is already in its second edition—and to Mr G P Barnard, whose recent treatise on the selenium cell, though perhaps not so critical a survey of the subject as it might have been, will certainly be regarded as a standard reference work

It may be said at once that the book under review cannot be classed with these Probably the authors did not intend that it should be, their claim being that the aim of the book is to introduce the general public to the modern 'electric eye', and to teach the layman its normal characteristics and its special idiosyncrasies

In spite of the authors' belief that the book presents an understandable account "not too technical for the untrained man and not too shallow for the specialist ", we would hesitate to say that it has achieved its object There are, however, certain classes of workers to whom the book will prove of use those interested in the construction of photoelectric cells, and more especially sound film engineers and others concerned with the general problem of amplification of photo electric currents and with any of the almost endless applications

The first six chapters are devoted chiefly to the theory and construction of the gas filled and vacuum cells, though the treatment is not so ex haustive as in Dr Campbell and Miss Ritchie's book A good deal of Chapter ii , on general theory, seems rather unnecessary Does the reader really expect, or want, a chart of the entire spectrum of radiant energy, or a description of black body radiation extending over several pages, in a book of this kind ?

Chapter vii is an isolated one entitled "Photo conductive and Photovoltaic cells ", and serves to illustrate the main criticism of the book, that in some chapters the treatment is not sufficiently thorough for the specialist This chapter, for example, introduces us to the selenium cell (to which Mr Barnard devoted 331 pages), the thalofide cell, and one or two photovoltaic cells, all in nine pages There is scarcely any further reference to them throughout the book

Two chapters (viii and ix) discuss various photocell circuits and the problem of amplification There are short chapters on the use of cells in sound-film work, the electrical transmission of pictures, and in television In a chapter on miscellaneous applications, some fifteen illustrations (again very condensed) are given of operations which the cell can perform The last chapter discusses directions in which progress may be expected towards the discovery of the ideal cell Several appendices are given at the end of the book F C T

Our Bookshelf

A Manual of Practical Vertebrate Morphology By J T Saunders and S M Manton Pp viii + 220 (Oxford Clarendon Press , London Oxford University Press, 1931) 15*s* net

THIS text book of practical work in vertebrate morphology covers the course for the first part of the Natural Sciences Tripos at Cambridge Its contents are as follows First, directions are given for the examination and dissection of the following types The lamprey, the skate, the whiting, the auditory ossicles and swim bladder of the roach, the salamander, the central and sympathetic nervous system of the frog, the lizard, the grass snake, the pigeon, and the brain of the sheep The authors have not included an account of a general dissection of a mammal, " as many excellent accounts of the dissection of the rabbit are easily available "

The descriptions are good and the dissections are well planned The authors have wisely refrained from inserting into these chapters discussions of the functions or evolutionary significance of the parts displayed, leaving such matters to the theo retical text books that must be read in parallel with a practical course of this nature But they append, after the chapters dealing with the dissections, a brief and highly compressed theoretical account of the vertebrate nervous system In the reviewer's opinion, it would have been wiser to leave this also to the theoretical books, where it can be given more spacious treatment Finally, there are four chapters dealing with the skeleton, in which the type system is abandoned and the different regions are taken one by one and examined in a great variety of animals

The book is attractively illustrated and contains a number of useful and original features

G P W

Science and Religion a Symposium Pp vii + 175 (London Gerald Howe, Ltd , 1931) 4*s* 6*d* net

IF a series of popular broadcast talks on science and religion is to be commended at all, the publica tion of the talks in print is certainly to be com mended, because the peculiar danger of this form of instruction is that there should be left upon the

mind of the listener a hazy impression, which he cannot clear up except by subsequent reading and thinking We do not agree with people who write to the papers to the effect that these talks are unsettling to those who listen to them 'The conflict between religion and science', to use the title of a nineteenth century presentation of the theme, has long been with us, but these talks exemplify the fact that there was never less real 'conflict' than there is at the present time Religion, or rather theology, has more or less adapted itself to the view of the universe taken by modern science, and the tone of men of science is very different from what it inevitably was so long as theology adhered to demonstrably impossible positions

The contributors to these twelve talks include five distinguished men of science, one philosopher, and six theologians—or, at any rate, churchmen We think anyone would agree that these twelve chapters are more suitable for careful reading than for mere listening, and that, to the intelligent reader, they may convey a fairly clear idea of authoritative opinion on the problems discussed He will gather also that when it comes to ultimate questions, there is divergence of opinion, not only between scientific workers and theologians, but also between, let us say, physicists and biologists, and he may be reminded of the proverbial query as to what is to be done when the doctors differ

Aeronautical Meteorology By W R Gregg, with the collaboration of C G Andrus, R N Covert, H M Hightman, V E Jakl, D M Little, F W Reichelderfer, J A Riley and R H Weightman Second edition, revised and enlarged Pp xvi + 405 (New York The Ronald Press Co, 1930) 4 50 dollars

This revised edition supplies, in a convenient form, the kind of meteorological knowledge which is required by the airman The author has since 1917 been in charge of the Aeronautical Division of the United States Weather Bureau, and is an acknowledged expert in upper air research There are sections contributed by other experts on fog, 'ceiling', and visibility, ice formation on aircraft, weather forecasting, instruments and methods of observations, airship meterology, and the Weather Bureau Airway Service

There is a discussion of the relative advantages offered by prospective Atlantic air routes and an account given of the meteorological conditions attendant upon Lindbergh's trans Atlantic flight A natural feature of the book is a representation of the various meteorological dangers that beset airmen, like squalls, fog, and ice, and one gathers that thunderstorms, for several reasons, should be given a wide berth As cloud scenery closely concerns the airman, the book is adorned by some handsome photographs of clouds The book, in fact, notwithstanding the amount of technical information which it is its purpose to give, is anything but dull reading, and the author shows his artistic sense in some enthusiastic tributes to the magnificence of thunder clouds

The Place Names of Galloway their Origin and Meaning Considered By the Right Hon Sir Herbert Maxwell Pp xlvi + 278 (Glasgow Jackson, Wylie and Co, 1930) 21s net

The English Place Name Society has introduced to a wider public the intense interest and value of a scientific study of place-names, especially in areas of racial contact The locality with which Sir Herbert Maxwell deals is particularly instructive from this point of view The great majority of the place names were originally in the Erse or Gaelic dialect No doubt they were perfectly intelligible until the introduction of Old Northern or Middle English Although they then remained unchanged, the ideas which had suggested them were forgotten Hence many of them can now be interpreted only through analogy with districts where Gaelic, Manx, or Welsh are still living languages Some, however, must, in the nature of the case, remain unintelligible, perhaps for ever Among the Galloway place names are names of rivers which, it has been suggested, may belong to the language of the aboriginal long headed, dark-haired population, and have affinities with Basque —an interesting suggestion, which unfortunately remains nothing more at present The author has some interesting and pertinent observations to make on the difficulties in the way of adopting the latest views on the ethnological problem of Celtic settlement The place names of Galloway belong to the *q* Celts, while the neighbouring area of Dumfries is Brythonic

Forged, Anonymous and Suspect Documents By Capt Arthur J Quirke Pp xii + 282 (London George Routledge and Sons, Ltd, 1930) 15s net

The public taste for amateur detective literature was largely stimulated during the last quarter of the nineteenth century, and the one amusing factor was the unwarranted contempt poured upon the Criminal Investigation Department at Scotland Yard In this book, however, Capt Quirke (handwriting analyst to the Department of Justice, to the Attorney General, and police headquarters, Irish Free State), whilst possibly somewhat patronising in his prefatory attitude to the police force, writes not as an amateur but as an official expert, mainly for the benefit of the legal profession and the police From the individuality of handwriting he proceeds, by way of an extended consideration of analytical methods, to the details of materials and processes, arriving eventually at an illuminating exposition of the ultra violet rays and the fluorescence test The infallibility of this test in the detection of forgeries, as proclaimed by him, is supported by its practical adoption by the Bank of England The author emphasises his views that not only are no two handwritings indistinguishably alike under test, but that this also applies to any two typewriters, even those of the same make and same age The longest and perhaps the most abstruse chapter deals with a practical analysis of handwriting, a systematic study of which might prove to be beneficial to the public at large P L M

Propagation of Magnetic Disturbances along Wires

IT is well known that the magnetisation of a ferro magnetic material changes in small steps (Barkhausen effect) We have shown [1] for a variety of materials that the sizes of these steps, or sudden changes in magnetisation, are independent of the sizes of the crystals of which the material is composed, and

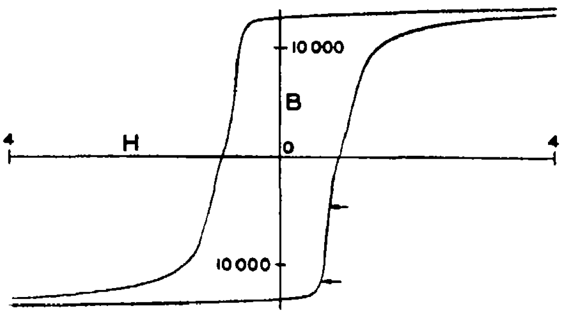

FIG 1 —Hysteresis loop of Armco iron maximum field strength 10 gauss

correspond to the sudden reversal of the magnetic moment of a volume of material of the order of 10^{-8} or 10^{-9} cm [3]

We now find that in many materials these small steps in magnetisation occur in groups of such size as to be detectable with a sensitive galvanometer This effect for iron is illustrated in the accompanying figures Fig 1 shows a hysteresis loop of Armco iron recorded photographically with the fluxmeter recently described by Haworth [2] No discontinuities are apparent here Fig 2 represents the portion of the loop lying between the arrows shown in Fig 1, recorded more slowly with greater fluxmeter sensitivity, and shows the large steps under consideration These steps appear only when the field is changed slowly, this is because it takes the magnetisation several tenths of a second to increase in any one step, and if during that time the field strength increased enough to set off the next change in magnetisation, the steps will not be separable While taking Fig 2 the field strength was changed 0 2 gauss per minute

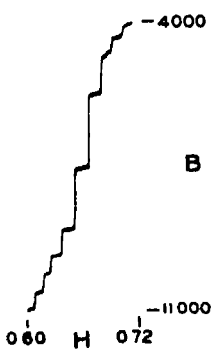

FIG 2 —Portion of loop of Fig 1, recorded slowly

That each such step in magnetisation is composed of a great many separate smaller changes is shown in Fig 3, where the whole record refers to the change in magnetisation occurring in one of the steps shown in Fig 2 Each sharp point of the record indicates one of the small steps or discontinuities discovered by Barkhausen The record was made with the usual arrangement [3] of search coil, amplifier, and oscillograph, used with a slowly and uniformly changing magnetic field strength

Separate tests have shown us that the change in magnetisation corresponding to one of the single steps of Fig 2 occurs throughout all sections of the sample, except near the ends, where the field is far from uniform This fact suggested that the magnetic disturbance was transmitted from one part of the sample to another by mechanical vibrations produced by the sudden change in length accompanying the change in magnetisation (magnetostriction) The other way in which the disturbance might be propagated is by magnetic influence alone According to the latter idea the increase in magnetisation occurring at one point increases the field strength and consequently the magnetisation at nearby points To distinguish between these two methods of propagation, an experiment was made as follows The large step like changes were made to occur over almost the whole length of the iron wire as before, but were prevented from occurring in a length of two centimetres in the middle by applying a field there in the opposite direction The sudden changes in the two halves of the wire were then found to be completely independent of each other, or incoherent, whereas with no back field in the middle they were always coherent Since elastic waves pass unhindered through the middle portion and experiment showed that no change in magnetisation occurred here, it is concluded that purely magnetic processes are responsible for keeping the disturbance going once it is started

We have examined similar disturbances in annealed iron wires so fine as 0 0017 cm in diameter and found that the changes in magnetisation are in much larger steps, a single step accounting for almost the whole change from saturation in one direction to saturation in the other These recall the results in hard drawn wires under tension and torsion described by Preisach [4] and by Sixtus and Tonks [5] In our own experiments, when the diameter is less than about 0 01 cm, the

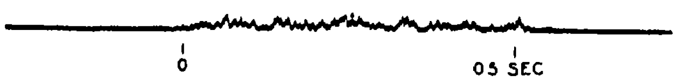

FIG 3 —Oscillograph record of one of the single steps of Fig 2 ordinates proportional to time rate of change of magnetisation

separate small Barkhausen discontinuities cannot be detected even with an oscillograph recording frequencies up to 4000 cycles per second The whole change occurs in one step and travels along the wire with a speed inversely proportional to the square of the diameter of the wire This also suggests that the magnetic field strength controls the propagation since the rate of decay of eddy currents varies inversely as the square of the diameter

The Earth's Thermal History

DR J H J POOLE has kindly pointed out to me that the reference to the adiabatic gradient of temperature in my previous letter [1] is capable of being understood to mean that he believes that the adiabatic gradient in a liquid heated below would not be maintained This was not intended , the maintenance of the adiabatic gradient by convection currents (or rather, of one exceeding it by the trifling amount

needed to start and maintain convection currents) is essential both to his views and mine. My point was simply that excess heat would be carried up by convection currents, as in the formation of cumulus clouds on a summer day, while a passage in his letter had appeared to cast doubt on this.

My own views on the earth's thermal history have undergone some change since my original criticism of Prof. Joly's theory, and Dr. Poole's theory also differs from the original (he does not appeal to Prof. Joly's bodily revolution of the crust to ensure resolidification). An important change on both sides has been in the recognition of the importance of the fact that the melting point gradient in rocks is steeper than the liquid adiabatic. This was first noticed by Dr. L. H. Adams and rediscovered by Drs. J. H. J. and H. H. Poole. My present views are given in "The Earth", second edition, pp. 138-148.

I have not yet had time to study Dr. Poole's paper[2] in detail, but it seems to me that its postulates differ from the geophysical problem in two respects. The earth is replaced by a deep vertical column, initially solid, with a non-conducting bottom. My view is that the earth was originally fluid throughout, and that it could never become solid throughout until such upward concentration of radioactive constituents had been achieved as to permit complete resolidification of the rocky shell. I think it improbable that the excess of the melting point gradient over the liquid adiabatic persists below a depth of a few hundred kilometres, so that the first solidification would be at an intermediate depth, and the condition at the lower boundary of the solid would be contact with a liquid in a convective state.

It seems to me that, apart from thermal considerations, there is a fatal defect in all theories requiring widespread weakness or fluidity in the lower layer of the earth's rocky shell (that is, between 30 km. and 3000 km. down) at any recent date. Evidence is accumulating to show that while isostasy is a first approximation to the truth, it is not exact. Heiskanen's ellipticity of the equator refers to the equipotential surface, not the solid surface. The corresponding difference between the mean and maximum radii of the equator of the solid, if the inequality is uncompensated, is about 0.7 km.; if compensated, it would have to be about 20 km., an entirely impossible amount.[3] The stresses involved in the support of this inequality must be distributed through a great depth, perhaps most of the thickness of the shell. There are several pieces of evidence tending in a similar direction, one of the most striking being the differences between the moon's moments of inertia, which must have persisted through most of the history of the earth. The recent work of the Indian Survey[4] and that of Dr. Vening Meinesz[5] constitute others. Now, if there had been any general fusion within a few hundred kilometres of the surface since these inequalities were formed, their pressure would certainly have displaced the liquid and restored the isostatic state.

I think we may go somewhat further than this. It is wildly unlikely that the material of the earth, at any depth, is a sufficiently pure substance to have a sharp melting point. For most geophysical purposes the melting point is the temperature at which the material acquires a sufficiently high viscosity to prevent convection currents; but the viscosity must vary continuously over a wide range of temperature. Now, in any theory of thermal cycles, after a solidification, heat transfer is by conduction and is a slow business. I think that in all such theories the variation of temperature in the solid between cycles is only a few degrees (except within, say, 50 km. of the surface). This applies to Prof. Joly's original theory, to Dr. Poole's modification, and to the various theories that Prof. Holmes has produced since he abandoned the theory of the earth's thermal history that he had done so much to establish, and which I still consider correct in essentials. To reconcile any theory of cycles with the observed imperfection of isostasy therefore requires that, in the lower layer, the strength of which supports the excess loads, a change of temperature of a few degrees corresponds to a change of mechanical properties, from sufficient softness to permit convection currents, to sufficient strength to support the stresses due to excess loads, normally of the order of 200 metres of material, and running up locally to some kilometres. It seems to me that the necessity of such a rapid change in strength with temperature in a substance without a sharp melting point is enough by itself to render any such theory untenable.

The Determination of Adsorption in Ternary Solutions

A NUMBER of attempts have been made to determine the adsorption of surface active substances from solutions containing salts, by the use of the Gibbs' equation, in the form

$$d\rho/d\mu_B = -\Gamma_B, \tag{1}$$

where $d\rho$ is the variation of the surface tension caused by a change $d\mu_B (= RTd \log a_B)$ in the potential of the substance B.[1] The complete equation of Gibbs as applied to a ternary system A, B, S is

$$\Gamma_A d\mu_A + \Gamma_B d\mu_B + \Gamma_S d\mu_S + d\rho = 0, \tag{2}$$

but if the dividing surface up to which the solution is supposed to be perfectly homogeneous is defined so that $\Gamma_A = 0$, this becomes

$$\Gamma_B d\mu_B + \Gamma_S d\mu_S + d\rho = 0. \tag{3}$$

This equation reduces to (1) when the variation of μ_S is negligible in comparison with that of μ_B. This will be the case when the concentration of B is very small, but will cease to hold at greater concentrations.

In dealing with a solution of A and B containing a salt S, it is more convenient in many cases to define the dividing surface so that $\Gamma_S = 0$, when (2) becomes

$$\Gamma_A d\mu_A + \Gamma_B d\mu_B + d\rho = 0. \tag{4}$$

This equation contains two unknown quantities Γ_A and Γ_B, which cannot be evaluated when the variation of $d\rho$ for known variations of $d\mu_A$ and $d\mu_B$ has been determined. But the composition of such a solution can be varied in two distinct ways: (1) by varying the proportions of A and B, keeping the amount of S constant; (2) by varying the concentration of S in solvents of fixed composition. For any given solution we may thus obtain two equations

$$\Gamma_A d\mu_A + \Gamma_B d\mu_B + d\rho = 0,$$
$$\Gamma_B d\mu_A' + \Gamma_B d\mu_B' + d\rho' = 0,$$

referring to variations of the two kinds mentioned, and these permit the evaluation of Γ_A and Γ_B.

In a binary solution of A and B, the surface *excess* Γ_B can only be identified with the actual amount of B present in the surface layer, when the concentration of B is small. In concentrated solutions, no method is available for determining unambiguously the composition of the surface layer.

It is evident that in the presence of a salt, which is

negatively adsorbed with respect to the other constituents, the method outlined may give a means of determining the actual composition of the surface layer

The measurements of the partial vapour pressures of water and alcohol in solutions containing various concentrations of lithium chloride which have recently been made in this laboratory by Shaw and Butler[3] provide the data required in these equations Mr A D Lees has determined the surface tensions of some of these solutions in order to test the feasibility of this method, and has obtained provisionally the following ratios for $\Gamma_{(alc)}/\Gamma_{(water)}$ in $1m$ lithium chloride solutions

Molar fraction of alcohol	6 4	25	80
$\Gamma_{(alc)}/\Gamma_{(water)}$	0 3	0 7	14

The vapour pressure measurements are being extended to solutions containing a lower proportion of alcohol, and it is hoped that eventually results will be obtained for a complete range of solutions

Disease in Nature

MOST naturalists would, I think, agree that wild animals have the appearance of exuberant health, and that it is quite unusual to meet with any obvious illness or disease But it is a very optimistic inference that civilised man might achieve the same state

So far as parasitic diseases are concerned, natural communities of animals, where there is no hygienic interference seem to come into a state of equilibrium with their parasites which is rarely broken through into either the complete destruction of the parasite or the appearance of an epidemic in the host Archdall Reid used to argue that human infections should be treated in the same way and left alone to do their worst

A great number, however probably the majority, of the bodily defects which give rise to the 'sub health' of human communities are due not to parasites but to age Man's body begins to decay at an age which varies widely in different individuals, but decay has generally definitely set in by the time a man is thirty his lungs are losing their elasticity, his aorta is getting fibrous, his respiratory and circulatory mechanisms are relatively inefficient few men can play first class football above thirty By forty five even his brain is growing smaller A large and increasing part of our population have, therefore, bodies which have deteriorated by the natural process of ageing, and there is no evidence that the enormous hygienic and medical advances of the last hundred years have done anything to postpone the effect of age The expectation of life at birth has nearly doubled, but for old men it is no greater than it used to be

In natural animal communities such age deteriorated individuals are eliminated by the ordinary processes of selection The same would presumably happen in man if survival depended on physical efficiency Artificial breeding experiments (for example, with mollusca) indicate that the possible length of life is much more than that usually attained in the wild state The wild populations are, therefore, healthy in a way which human populations can never hope to achieve It does not seem likely that hygienists can do anything very effective in altering the tissues on which injurious agents work, though they can, of course, do much in protecting man from such agents Whether the age at which the body begins to go downhill is a heritable quality I do not know it probably is, for length of life is intensely inherited The most likely eugenic procedure seems, therefore, to be to select for age at death

A E BOYCOTT

17 Loom Lane, Radlett,
Herts

THE discussions in NATURE of April 25 and May 9, on the occurrence of disease among animals and plants living under natural conditions, are of importance from several points of view, both economic and scientific While I do not admit the validity of the reviewer's distinction between internal predators and diseases, yet, for the sake of the argument, we can eliminate the huge death roll of insects due to insect parasites and still leave a large death roll due to diseases

Bacterial diseases are common among insects, especially during the larval stage, the larvæ of Lamellicorn beetles living in the soil being very subject to attacks of bacteria In the tropics many Lepidoptera larvæ suffer from such diseases Fungal diseases among insects are common all over the world, but more noticeably in tropical rain forests, where they are sometimes the chief controlling factor in limiting the numbers of some insects Economic entomologists are familiar with these facts

Insects attacked by these diseases show all the signs of 'disintegrative and deteriorative disturbances" shortly before death By saying that these insects are 'diseased' I may be "influenced by human prejudices', as Mr Maulik contends, but if we use the word in connexion with human beings, then it is also applicable to other animals No one would ever talk of Nature being 'diseased' or 'healthy', but we can apply those terms to animals and plants The word 'disease' is more convenient than the phrase "disturbed balance of metabolism"

Disease among insects leads to a speedy death, and the superficial observer only notes the active, healthy specimens In spite of the great importance of a correct knowledge of the death factors of animals and their relative values as selective factors, in our understanding of natural selection, only superficial attention, so far, has been given to this subject Among insects the greatest mortality falls upon the eggs and young, perhaps some eighty per cent, and the chief death factors are diseases (including parasitism) If we ignore this fact and base our statistics upon the idea that all, or the greater part, of the mortality falls upon the adult, and has selective value, we are likely to reach wrong conclusions For this reason, if for no other, it is necessary to recognise diseases (including parasitism) among insects, and their overwhelming value as death factors

Vegetable Juices as Fixatives

SINCE the article on "A Modified Gold Chloride Method for the Demonstration of Nerve Endings" was published by Mr Fred W Cairns, of Glasgow,[1] we have been experimenting with vegetable juices, other than lemon This communication is intended only as a preliminary announcement of the uniformly satisfactory and constant results that we have obtained with them, and we hope to be able to publish an account of our investigations in greater detail soon in the *Mysore University Journal* The following

juices have been employed, both for the purpose of demonstrating the nerve endings and for general histological investigations, with great success Onion

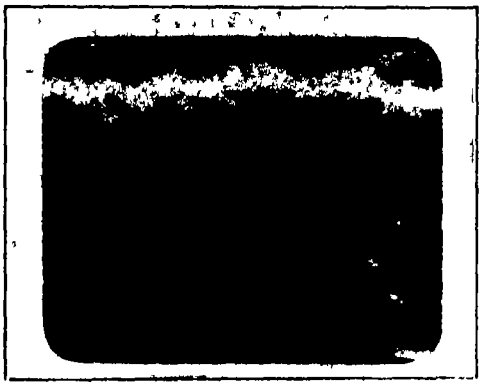

FIG 1 —Corpus luteum of domestic rat fixed in onion juice and stained with hæmatoxylin

FIG 2 —Nerve endings in the diaphragm of *Loris* onion formic gold chloride

FIG 3 —Nerve endings in the intercostal muscles of *Loris* citric formic gold chloride

juice (*Allium cepa*), mango juice, green and unripe (*Mangifera indica*), tamarind juice, green and unripe (*Tamarindus indica*), gooseberry juice (*Phyllanthus emblica*), sour milk (whey)

Three photomicrographs are here reproduced (Figs 1, 2, 3) to show the degree of accuracy and detail which may be obtained by these new methods

In addition to the above juices, we have also used uric acid from the urine of the pigeon, and also cow's urine, besides citric and formic acids We may only note here that vegetable juices with formic acid and 5 per cent formalin separately in certain proportions, which we shall announce soon, have also given very satisfactory results

Occurrence of *Protodrilus flavocapitatus* at Port Erin

BRITISH Archiannelids are so few in number, and their habitats so little known, that any new observations on their occurrence are well worth recording

One of the smaller members of the group, *Protodrilus*, was first taken in the adult condition on the south coast of England in 1913 [1] in a peculiar habitat, namely, just below H W neaps under stones embedded in fine gravel (pebbles 1 5 mm with larger constituents) and in the gravel itself in localities where fresh water runs into the sea It was later discovered in abundance in similar habitats—usually accompanied by the planarian *Procerodes ulvæ* (=*Gunda*), the isopod *Jaera marina*, and various Oligochæts and Gammarids—at numerous situations on the south and west coasts from Exmouth to Woolacombe, near Ilfracombe [2, 3] In June 1929 and April 1930 a careful but unsuccessful search [4] was made for this animal (by one of us, J H O, and Miss M K Molyneux) in the locality of Port Erin, in the Isle of Man

The search was continued this year and this interesting primitive worm found early in April in Port Erin Bay on Traie Vane and Spaldrick beaches, in habitats similar to those previously described [3] At other localities near Port Erin, namely, at Fleshwick Bay, Port St Mary (Mill Stream), and Perwick Bay, where streams run into the sea, *Procerodes*, *Jaera* and the other normal associates of *Protodrilus* were again found,[4] sometimes in great numbers, but the Archiannelid itself was not seen Comment on the apparent absence of *Protodrilus* from these localities is of little use at present, but a review of the habitats where the animal has been taken indicates that the following are important factors in determining the habitat (1) stones lying on fine gravel or coarse sand at about to a few feet below the level of H W neaps in (2) situations remaining at least damp at low tide, (3) the proximity of fresh water, and (4) protection from direct wave action In view of Pantin's recent work [5] on *Procerodes*, an additional factor is probably (5) the necessity for a certain concentration of calcium ions in the fresh water stream

The presence of shelving rocks below the H W neap zone undoubtedly affords the measure of protection from wave action conducive to a *Protodrilus* habitat, while in northern latitudes it is possible that beaches exposed to sunshine, as are those of Traie Vane and Spaldrick, are more suitable than others for a member of the genus *Protodrilus*, the centre of distribution of which is Lusitanian

The seepage water in which *Protodrilus* was living on the exposed beach at Traie Vane was found to vary in temperature closely with the air, except just after the recession of the tide A temperature so low as 7 5° C was recorded, but much lower readings would be obtainable in winter, the salinity showed only slight variations, as the fresh water stream was nearly

dry (about 29 to 33 per mille at pH 7 9 to 8 2 (corrected), as kindly determined by Mr J R Bruce), but lower salinities would occur after heavy rains On the south coast of England the animal has been taken in water which was almost fresh [1]

It is possible, therefore, that *Protodrilus* may occur in suitable habitats as far north as Scotland

The occurrence of 'red head', ventral eye spots, bifurcate caudal appendages, segmental cilia, and the characteristic numerous epidermal glands figured by Pierantoni [6] define the species as *Protodrilus flavocapitatus*, Uljanin, which, however, attains a larger size (lengths of 20 mm being common) than that recorded by Pierantoni

Wheat Surplus and its Cause

THE comment made by Prof Piaggio in NATURE of March 21, upon the address by Sir Arthur Eddington, cites the famous prophecy by Sir William Crookes, made near the end of the last century, as to the probable wheat supply in the future, say thirty years from the time of his address The comment indicates that the present wheat surplus is due to the recent advances in fixing nitrogen and making new fertilisers Sir William Crookes saw future controlled nitrogen fixation as the gleam of light amid the murky gloom of anticipated short wheat rations While modern fertilisers may have had a slight influence in bringing about the present flood of wheat, their effect has certainly been a minor one

The increase in the world's wheat production above what was anticipated is a complicated problem, but the utilisation of new types of machinery has certainly been a dominant factor Sir William Crookes instances eight States of the U S A located in a region "so arid as to be of infinitesimal value for food production relatively to the whole area" (with regard to tillable land) While he cites but 810,000 acres of this large area as devoted to wheat in 1897, we find that in 1929, thirty two years later, the wheat land of this region had increased to 7,500,000 acres, with a production of 100,600,000 bushels This nearly tenfold increase, in a region where further increase seemed impossible, has come about almost entirely because of the introduction of power machinery and the greatly increased utilisation of the combine harvester Other regions would tell a similar story Sir William Crookes's dictum was that the world's average yield per acre would have to be increased very materially to make up the impending shortage, and that such an increase would necessitate the comparatively abundant use of nitrogenous fertilisers This has not proved true

Origin of *Spartina Townsendii*

FROM its characteristics and the circumstances of its origin, Stapf [1] and others have concluded that the cord or rice grass, *Spartina Townsendii* H and J Groves, must have originated on the foreshore of Southampton Water as a hybrid between *S alterniflora* and *S. stricta* The only objections to this have been raised on the ground that it is fertile and breeds true to type

Cytological study has shown *S Townsendii* to have 126 chromosomes in its root tip cells—nearly double the highest number previously reported in the Gramineae—and its putative parents have been found to have 70 and 56 respectively Those observations support the assumption that *S Townsendii* is of hybrid origin and, further they explain its fertility and its true-breeding behaviour It is an allopolyploid similar to *Primula kewensis* and other recent experimentally produced plant species

S alterniflora is generally considered to be an introduced species from America, while *S stricta* is native The hybridisation and chromosome doubling which have given rise to *S Townsendii* occurred in Nature, without human agency, but yet in such circumstances as almost to approximate experimental control *S Townsendii* has almost completely eliminated its parents wherever it has come into competition with them, and has spread very widely from its centre of origin It emphasises the fact that one of the results of allopolyploidy is the maintenance of hybrid vigour, and is a striking example of the significance of hybridisation followed by polyploidy in plant evolution, as it seems to rise above the objections which have caused some authors to hesitate in their admittance of full specific rank to newly originated allopolyploids

The economic significance of *S Townsendii* has been widely discussed and need not be considered here

A more complete account of the cytological observations is being published in *Genetica*

The Altitude of Bird Migration

IN NATURE of April 18, T B Blathwayt records a party of egrets observed (through a telescope) migrating at night, and about five thousand feet up, and he asks if there are other records of a similar nature

In America some valuable material has been collected on the altitude of flight, by means of telescopic observations, but in Britain and elsewhere most of the scanty data have been obtained from aeroplanes Chapman [1] collected altitude records for 262 birds crossing the face of the moon, all between 1500 ft and 15,100 ft Scott [2] noted large numbers of birds migrating between five and ten thousand feet, and Carpenter [3] recorded birds passing over by night between 1400 ft and 5400 ft, while Winkendwerder [4] compiled a mass of information on migration by making telescopic observations

Meinertzhagen,[5] in a review of the whole subject, gives thirty six records of birds above 5000 feet (excluding the American work cited above) The greatest altitude for migratory flight known to me is that recorded at Dehra Dun, India, where a party of geese were accidentally included in a photograph of the sun, these birds were estimated to be flying at 29,000 feet [6] Lammergeiers, godwits, curlews, and choughs have been observed above 20,000 feet on Everest, and a number of birds (perhaps cranes) were noted from an aeroplane at 15,000 feet during the War [7]

There can be little doubt that the main bulk of migration (much of which passes by night) occurs at less

than 3000 feet But our knowledge is still far from complete, and all who may obtain observations on this subject should follow Mr Blathwayt's example by putting the occurrence on record (even if the species is not identified)

Ultra-Violet Absorption and Raman Effect for Hydrazine

THE ultra violet absorption in hydrazine vapour, N_2H_4 (saturation pressure over the liquid at room temperature), consists of five or six nearly equidistant intensity maxima at about 2326, 2320 2276, 2250, 2225 A, followed by continuous absorption, beginning at about 2200 A and extending into the whole quartz region [1] The band absorptions are entirely devoid of rotation structures at 5 4 A per mm dispersion

To obtain some knowledge about the mechanism of dissociation shown at 2200 A, I have also photographed the Raman spectrum of the same substance using a column of liquid 1 cm in diameter and 10 cm in length, irradiated by a suitably filtered mercury arc so that only the radiations at 4047 A and 4359 A are effective (details of the experiment to be published in the *Scientific Papers* of this Institute)

Two sets of five sharp modified lines are observed under low dispersion, simply displaced by the separation of the two exciting lines, with the following frequency shifts from their respective lines of origin

$\Delta\nu$ (cm^{-1}) *a*, 900 (weak), 1120,
b, 3212, 3289, 3339

The *b* lines are nearly of the same intensity and agree very well with the triplet observed in liquid ammonia (NH_3) by Daure[2] and others They represent undoubtedly the *internal* vibration frequencies of the N H or NH_2 group, the last one corresponding to the absorption centre of the 3μ band of ammonia (3337 cm^{-1})

Now, Dadieu and Kohlrausch[3] interpret Daure's line of lower frequency, 1070 cm^{-1} of ammonia as due to the single bond vibration in the polymerised molecule $H_3N\ NH_3$ with quadrivalent nitrogen supposed to exist in liquid ammonia If this is true, my 1120 line is safely attributed to the N H (single bond) vibration in the hydrazine molecule

The hydrazine used was prepared from the hydrate $N_2H_4\ H_2O$, and the weak line at 900 cm^{-1} is probably due to hydrazine hydrate molecules still remaining This point I hope to verify with pure hydrate, but at the moment the substance is rather difficult to obtain

It is not difficult to imagine that the N N binding is very much loosened in an excited gaseous state, and the 500 cm^{-1} vibration frequency observed in ultra violet absorption may arise from this The dissociation of hydrazine vapour by 5 5 volt light absorption therefore seems to be effected by the breaking of the excited molecule in the middle Considering the sharpness of the spectrum, the bands preceding may be regarded as a structureless predissociation spectrum

Crystal Structure of Chromium Trioxide

SMALL thin red needles, heavily striated down the prism, were prepared by adding concentrated sulphuric acid to a cold concentrated solution of potassium dichromate The crystals were sealed up separately in thin glass tubes to prevent deliquescence Measurements on an ionisation spectrometer and from oscillation photographs gave the value of the cell size as $a = 8\ 50$ A, $b = 4\ 73$ A, $c = 5\ 72$ A, the probable error being not greater than $\pm$ 1 per cent The density given by Groth is 2 73–2 82 and there are therefore 4 molecules per cell The axial ratios given by Nordenskjöld[1] are $a\ b\ c - 1\ 0\ 69\ 0\ 63$ The relation between his ratios and ours is $a\ b\ c$ (Wooster) = $a\ \tfrac{3}{2}b\ c$ (Nordenskjöld) The only face from which he could obtain the ratio $a\ b$ should have been indexed (230) instead of (120) All the specimens which we have examined up to the present are mimetic twins on (110), closely simulating hexagonal symmetry

Ionisation and photographic investigations show the following halvings

(hkl) when ($h + k$) is odd
($0kl$) when l is odd

These suggest the space group Q_h^{17} - *Ccmm* and the co ordinates of the chromiums are as follows, the centre of symmetry being taken as origin $u, 0, \tfrac{1}{4}$, $\bar{u}, 0, \tfrac{3}{4}$, $\tfrac{1}{2}+u, \tfrac{1}{2}, \tfrac{1}{4}$, $\tfrac{1}{2}-u, \tfrac{1}{2}, \tfrac{3}{4}$ The value of u is doubtful, because the intensities are disturbed by the twinning, and fall off very rapidly, but u is probably about $\tfrac{1}{8}$ The observed halvings appear to require a structure consisting of tetrahedra of CrO_4 linked together in chains parallel to the c axis This would explain the cleavages, which are very well marked parallel to this direction and tend to cause the crystal to break up into fine needles

The work will shortly be continued at low temperatures and published in the *Zeitschrift fur Kristallographie*

Deep Focus Earthquakes

IN a letter published in NATURE of Mar 28 (p 486), Mr F J Scrase, referring to an earthquake which was registered at Kew Observatory on Feb 20, explained briefly how it was possible to recognise the abnormal depth of focus and to make an estimate of this depth Confirmation of the deep focus of this earthquake has now appeared in a Seismological Bulletin issued by the Jesuit Seismological Association of America

From the fact that the primary pulse (or P wave reached Kew, Pasadena, and Riverview almost simultaneously, it is deduced that the epicentre of the earthquake was in latitude 44° N and longitude 135° E, about 200 miles from Vladivostok At every station for which the records have been examined, the interval between the times of arrival of the P and S waves was abnormally short for the distance from the epicentre Moreover, the arrival time at La Paz of P' (the horizontal wave which passes through the earth's central core) is about one minute early, and, as La Paz is at an epicentral distance of about 150°, this early arrival strongly supports the other evidence for deep focus

Applied Geophysics

IN opening to the public a geophysical exhibition, and in publishing a handbook* which not only is descriptive of the exhibits but also constitutes an admirable historical résumé of and introduction to the study of applied geophysics, the Science Museum, South Kensington, has taken an important step in promoting the development of this branch of science, a step which is particularly appropriate at the present moment in view of the growing appreciation in Great Britain of the practical value of these relatively new methods of exploration The exhibition is specially arranged to demonstrate the nature of geophysical prospecting operations, the various forms of instruments and field equipment employed, and the types of practical problems with which they are capable of dealing Certainly, never before in Great Britain has there been a better opportunity for geologists and mining engineers to familiarise themselves with a subject which is rapidly becoming an important factor in the development of the world's mineral resources

In the handbook, the four principal geophysical methods (magnetic, gravimetric, seismic, and electrical) are dealt with individually In the first half of the book, an eminently readable and well-balanced historical account is given of these methods, with explanations in simple language of the general physical principles on which they are based Although the literature of applied geophysics is extensive and in many languages, it is not readily accessible to the public, but in these pages there is ample evidence of an extensive research into the development of the various methods and regarding the most recent practice both in Great Britain and abroad The sane outlook which is reflected will do much to dispel any misunderstandings which may have arisen in the minds of some in consequence of exaggerated claims or unduly sceptical opinions regarding geophysical methods of exploration that have occasionally appeared in print

It is appropriate that an authoritative work on this subject should begin by dispelling the popular misapprehension that there is some connexion between geophysical exploration and the divining rod an instrument which is aptly described on the second page as "an unscientific device depending on real or imaginary supernormal faculties possessed by certain individuals" This definition will be in accord with the opinions of most geophysicists and geologists The persistence of the popular belief in the divining rod is truly remarkable, and it may be of interest to mention that in certain of the more remote parts of the British Empire the faith in this device for locating water is so ingrained that professional diviners are still employed upon the staffs of some government departments

Although the full theory of the several geophysical methods requires a somewhat specialised study, the fundamental principles which underlie their applications to the search for mineral deposits and to the investigation of geological structures are relatively simple, and thus it will be readily appreciated that most minerals of economic importance possess some characteristic feature by which they may be distinguished from the barren rocks which enclose them For example, some iron ores have distinctive magnetic properties, whilst most metalliferous minerals have a relatively high density Amongst the latter there are many which are also good conductors of electricity, the sulphide ores of iron copper, and lead being notable examples In the non-metallic group of minerals there are not so many outstanding cases, but advantage may sometimes be taken of the low density of certain types of coal, and several important discoveries of oil are due to the fact that rock salt also has distinctive physical properties, namely, a low magnetic susceptibility, a relatively high density, and a high elasticity In the coastal oilfields of Texas and Louisiana, the oil is characteristically associated with large plug like masses of salt Although the oil cannot be detected directly, it has been possible to locate these *salt domes* by geophysical methods, and thus to discover the oil bearing ground Magnetic, gravimetric, and seismic methods have all been used for this purpose, the success obtained by the latter being most remarkable

The physical properties upon which the magnetic, gravimetric, seismic, and electrical methods are based are, therefore, those of magnetic susceptibility density, elasticity,† and electrical conductivity Whilst the magnetic and gravimetric methods are concerned entirely with naturally occurring phenomena (anomalies in the earth's normal magnetic and gravitational fields), it is apparent that the elastic and electrical properties of a concealed body are quite inert, except in response to an artificial applied stimulus In the case of the seismic method, waves are propagated in the ground by means of explosive charges which are usually buried a few feet below the surface The speeds with which these waves travel are measured with portable seismometers, and by plotting a series of time distance graphs for each explosion, the structural features of an area may often be determined with a high degree of accuracy In the electrical methods, current is applied to the ground, either conductively by means of earthed electrodes or inductively by insulated loops of wire which are connected to a source of alternating current A search is then made with suitable

* Board of Education Science Museum Applied Geophysics a Brief Survey of the Development of Apparatus and Methods employed in the Investigation of Subterranean Structural Conditions and the Location of Mineral deposits By Capt H Shaw, with the assistance of J McG Bruckshaw and S T Newing Pp 101+10 plates (London H M Stationery Office, 1931) 2s net

† The velocity of propagation of a seismic wave through the ground is determined by the elastic constants and densities of the various geological formations that constitute its path $V = \sqrt{\frac{\text{Elasticity}}{\text{Density}}}$ is the general expression of this relationship

instruments (potentiometers, search coils, etc.) for departures from a normal current distribution or, in the inductive methods, for anomalies in the associated magnetic field. In favourable circumstances, it is possible in this way to locate the positions of conductive deposits lying several hundred feet beneath the surface.

What has been said with regard to mineral deposits also applies in principle to certain rocks and geological structures, a detailed knowledge of which is sometimes required for special purposes, such as oilfield exploration and various types of engineering problems. Although the contrast in physical properties between contiguous geological formations may not be so marked as between mineral deposits and their enclosing rocks, this fact is often compensated by the difference in scale of the two classes of investigation. Structural problems of the type referred to are usually concerned with large scale geological features in which a relatively small but consistent difference in a physical property may afford a satisfactory basis for a geophysical survey. Thus, the axis of an anticline may sometimes be determined from the fact that the material which constitutes its core is commonly of a somewhat higher density than the formations forming its flanks. A fault displacement may also be revealed quite clearly by a comparatively small difference in the mean magnetic susceptibilities of the rocks lying on each side of it.

The second half of the handbook issued by the Science Museum is descriptive of the numerous exhibits which, until the end of June, will remain open for inspection there. Although the full benefit from these pages can scarcely be obtained without a visit to South Kensington, the descriptions of the instruments are so lucid and well illustrated that there is much to learn from them alone. The historical range covered by the exhibition is very wide; in the case of the seismic method even dating back to a seismoscope made in China in A.D. 132, and in the magnetic method to an instrument made by William Gilbert in the year 1600. Of equal interest, however, and perhaps of greater importance from the point of view of the geophysicist of to-day, is a series of modern instruments, several of which are of so recent a design that they have not previously been seen in public.

Particular attention may be directed to certain of these modern instruments with which considerable experience has been gained by the Imperial Geophysical Experimental Survey during the past two years. This Survey, it will be remembered, has been conducted in Australia under the joint auspices of the British Empire Marketing Board and the Commonwealth Government, with the special object of testing the four principal geophysical methods under a variety of field conditions. The work of the Survey has now been completed, and a full report, under the title "The Principles and Practice of Geophysical Prospecting", will be available shortly.

In the magnetic section the Schmidt vertical variometer occupies an important position, since it is probably the best known and most extensively used of the more recent types of magnetic field instrument. It is intended for quick and accurate determinations of the relatively small anomalies in the earth's magnetic field that exist in the neighbourhood of certain types of mineral deposit and rock formation, and although well designed to withstand vigorous field conditions, it is certainly more portable and simple to use than any ordinary survey instrument, such as a theodolite or level. Experience in Australia with two of these magnetometers has shown that they are capable of detecting minimum variations in the vertical component of the order of 10γ (that is, 10^{-4} gauss), and that a careful and conscientious person is capable, after half an hour's instruction, of carrying out a complete series of field observations.

In general, it is found that the position of a hidden magnetic body or the details of a concealed geological structure are revealed most effectively by determining the variations in the vertical component of the earth's magnetic field at a series of points in the area in question, and by plotting the results of the survey in the form of lines (magnetic contours) joining all points at which the values of the anomaly are the same. In Australia the form lines of the Jurassic bedrock over a portion of the Victorian brown coal field were studied in this way, and by a somewhat similar method it was possible to delineate a complex system of Tertiary basalt flows which lies beneath an alluvial sheet in one of the New South Wales goldfields. The magnetic method has so many applications, and the observations can be carried out so rapidly and cheaply, that it is surprising that its importance as an auxiliary to geological survey work has received so little attention until within the last few years.

Amongst the gravimetric instruments, the gravity gradiometer is one of the most interesting, since it is a comparatively new development specially designed to comply with the two principal needs of the working geophysicist, which are portability and speed of operation. Advantage has been taken of the fact that the *gradient of gravity* is the primary requirement in a gravimetric survey, and that in the majority of economic investigations the *curvature values* may be neglected without materially impairing the value of the results. By eliminating the effects of curvature, it has been possible to produce an instrument (the gradiometer) in which very substantial reductions in the overall dimensions and in the free period of the beam have been effected. Two of these small balances were used in Australia by the Imperial Geophysical Experimental Survey and it was found that the gradiometer principle has much to commend it. Although less sensitive than the normal type of torsion balance these instruments are adequate for many practical purposes, and the advantages gained from the ease with which they are transported to the site of work and moved from one station to another, and from their increased speed of operation, are so great as to render them preferable for most surveys where curvature values are not essential. If curvature effects and a higher degree of sensitivity are required, then recourse must

be had to the larger types of instrument that are represented in the Exhibition

In Australia the principal use of the gradiometers was in determining the dispositions and boundaries of a concealed portion of the Victorian brown coal deposits, and they proved quite effective for the purpose One of the instruments used by the Survey is included in the Exhibition and may be compared with the most recent model which has been made by the Cambridge Instrument Company

The display of electrical prospecting instruments certainly merits special attention, since this appears to be the first occasion on which geophysical equipment of this kind has been open to public inspection In this connexion it is interesting to recall the following statement which appeared in 1927 in a report on geophysical surveying by a sub-committee of the Committee of Civil Research "In particular, the electrical method has throughout been treated as a jealously guarded secret trade process In the result, little information is available to the general scientific world regarding the methods employed the apparatus required, the field operations, or the interpretations of results We believe that a full disclosure of the scientific facts would tend, more than anything else, to stimulate the natural development of this method of geophysical surveying, by placing it on a scientific footing, similar to that of the gravimetric method"

During the past few years, efforts have been made to remedy this position, and it is hoped that the forthcoming report of the Imperial Geophysical Experimental Survey will be found to assist in this direction to a substantial extent Electrical methods were used in many parts of Australia, and several of the instruments which were developed and used by the Survey are to be seen at the Science Museum, with examples of the latest patterns which have resulted from the field experience gained during these investigations Amongst these are the standard types of equipment used in the well-established equipotential line and spontaneous polarisation methods, and the Bieler-Watson double coil, with which inductive fields are investigated, and the ratiometer apparatus which was described in NATURE of Jan 3, 1931, p 37, are also to be seen A further exhibit is the 'Megger' earth tester, which is now being used extensively in connexion with earth resistivity surveys

It is noteworthy that although the foundations of these four principal geophysical methods lie predominantly to the credit of pure research workers in Great Britain, the development of their practical applications is largely due to foreign enterprise, mostly on the Continent and within the last ten years in particular Although we must admit a serious lag in this important phase of the work, considerable satisfaction is to be derived from the ample evidence afforded in the Science Museum of the fruitful activity now being displayed by British geophysicists and instrument manufacturers It is also gratifying to know that this Exhibition is not the only step being taken in responsible quarters to ensure that the science of applied geophysics shall continue to be developed in Great Britain along progressive lines

A BROUGHTON EDGE

Ultra-Penetrating Rays *

By Prof H GEIGER, Tübingen

ABOUT twenty years ago we first noted the presence of a γ-type radiation of high penetrability, probably of cosmic origin, passing through the atmosphere The first fundamental experiments carried out by Hess and improved on by Kolhörster, in which an air-tight electrometer registered the ionisation current at different altitudes, showed us that the current increased with the altitude, at not more than a few thousand metres the current was several times larger than at sea-level These results indicated the presence of an extremely penetrating radiation, which seemed to be markedly absorbed by the atmosphere above us Great difficulties were met with in studying the nature of this remarkable radiation, due principally to its extremely weak intensity, high penetrability, and lack of properties affected by external influences Our knowledge progressed slowly, and only after many years of experimentation were we able to say that the penetrability is about ten times greater than the hard γ-rays of radium, and that the ionisation in air at sea-level is slightly more than 1 ion per second per cubic centimetre We were able to add that in the explorable regions of the atmosphere the radiation was diffuse, and, further, there seemed to be no relation to the daily movement of the sun Even at the present time, we cannot say with certainty that the variations observed in the intensity of the radiation are wholly of atmospheric origin or partly an intrinsic property

The doubtful origin and nature of this radiation continued to occupy our attention The old experimental methods had been exhausted and new ones had to be evolved to insure a better understanding of the problem During the past few years, we have progressed in two directions, namely, along electrometric lines by the improvement of the registration and the application of high pressure chambers, and by the method of electron counting In the pressure chamber the degree of ionisation produced in the gas by the ultra-radiation is measured, while in the tube electron counter the high velocity electrons coupled with the ultra-radiation are registered singly

The results obtained with these methods, in so far as they promise to aid in solving the problem, are discussed below Three experimental categories are apparent absorption measurements and the determination from the absorption coefficient of the energy of the radiation quantum, further, the coincidence measurements from which range and other properties of such high energy electrons, which are associated, if not identical, with ultra-radiation,

* Opening paper of a discussion at the Royal Society on May 14

can be studied, the last, which on further development will probably give us the important data, embraces those effects taking place at the boundary of two adjacent media

The principal aspect of the first of the above divisions is the hardest component of the complex ultra radiation Detailed knowledge is necessary here in order to analyse the complex absorption curve With the aid of well known formulæ, a knowledge of the coefficient of absorption enables us to determine the highest energy quantum The extremely thick layers of material necessary to reduce the intensity of the hard component of radiation to a small fraction thereof are scarcely available, but we may well use the great depths of water in certain lakes Regener has extended the noteworthy absorption experiment of Millikan and others by lowering his apparatus successively to depths of 236 m in Lake Constance The essentials of the apparatus are a pressure chamber with quartz fibre electrometer attached, where the deflections are photographically recorded every half hour by the automatic illumination of the quartz fibre At the greatest depths, where the ionisation was smallest, the successive half hour records were close to one another and the registration could, therefore, be continued for days at a time, but at the surface of the lake, the ionisation was so large that the quartz fibre completed its run in about five hours

By another series of experiments, Regener replaced the ionisation chamber by an electron counting tube, the record in this case being made by a small adding machine The sums registered were recorded every hour photographically on a slowly rotating plate On the surface, such a counter registered about 8000 electrons an hour, but at the depth of 235 m only 13, the residual effect of 500 particles per hour is, of course, subtracted from the above Both methods gave the same absorption curve, and showed, especially for the hardest component, which practically alone is present at depths from 80 m to 235 m, an absorption coefficient of 0 020 per metre water In other words, a thickness of 35 m water is necessary to absorb half of this radiation, which on the Klein Nishina formula gives a wave length of $0\ 63 \times 10^{-13}$ cm

A completely different view of the nature of ultra radiation was the result of a second series of experiments, in which the coincidences of two neighbouring tube counters were observed In this fundamental work of Bothe and Kolhörster, which was later extended by Rossi, two counters were mounted, one about 5 cm above the other Simultaneous photographic registration showed that quite a number of impulses occurred in both counters at the same time It is difficult to explain this phenomenon other than by the presence of fast electrons which pass through both counters In general, one would expect the presence of fast electrons associated with such penetrating radiation, however, the penetrating power of these electrons was of a very high order, practically as high as that of the ultra-radiation itself This was observed by placing a block of gold 4 cm thick between both counters, in this block only about 25 per cent of the radiation was absorbed

Regarding these experiments alone, one cannot help thinking that ultra-radiation is not of a wave nature, but consists rather of high velocity electrons This, indeed, was the general conclusion arrived at by Bothe and Kolhörster

Be that as it may, it is necessary to intensify all experimental methods to determine further the nature and properties of such ultra electrons Heidecke, in Tübingen, took steps in this direction, he measured the scattering of these electrons occurring in their passage through matter With the aid of two counting tubes (A and C), 21 cm apart vertically, he observed the coincidences which indicated the passage of ultra electrons through the spherical angle defined by both tube counters If a third tube counter B were so placed that the horizontal axes of all three were parallel and all in the same vertical plane, one would expect the middle tube to count simultaneously with the coincidences of the outer tubes (triple coincidence) To a large extent this was observed On moving the lowest tube C horizontally parallel to its original position, the expected reduction in the number of triple coincidences was observed In certain positions of C, an increase rather than a reduction in the number of triple coincidences was observed when a 5 cm lead plate was placed between B and C This can be explained by the scattering of a number of electrons by the lead which were registered by the tube C in its new position, this effect can scarcely be accounted for without scattering

We can now discuss the third group of experiments, which deal with transition effects Hoffmann, Steinke, Myssowsky, and others have found that by the passage of ultra radiation from one medium into another, absorption peculiarities take place For example, on passing from a less dense medium, such as aluminium, to a more dense medium, such as lead, the radiation is more highly absorbed in the first stages of transition in the second medium One is led to believe that the passage of the ultra-radiation through the lighter element results in the emission of soft secondary radiation Steinke, with an extremely sensitive compensation method, in which a Hoffman electrometer served as null instrument, could show that on placing an aluminium plate in the path of the rays the intensity of ionisation was increased instead of diminished

In my laboratory, similar experiments were also carried out, but with tube counters In one of these studies, a 5 cm thickness of lead and an equal thickness of aluminium were so placed that the ultra-radiation passed first through the lead and then through the aluminium before entering the counter After first determining the number of electrons in a given interval of time, the measurements were repeated with the plates reversed By interchanging the plates the absorption should have been the same, and a possible secondary radiation would have been noticed if it did not accidentally occur with equal intensity in both metals The

experiments, in fact, showed that with aluminium facing the tube counter, 5 per cent more electrons were recorded than in the reverse case A portion at least of the secondary radiation thus consists of fast electrons By varying the plate thickness as well as material, the penetrating power of such secondary electrons could be determined In the three substances investigated the range was approximately inversely proportional to the density and amounted in aluminium to about 4 cm These electrons, when compared with the ultra electrons, are extremely weak, yet of greater energy than those inherent in radioactive processes

It is not easy to interpret the origin of these observed electrons To take them for Compton electrons is scarcely permissible, for then their low and limited energy content cannot be explained furthermore, the slow electrons actually observed would then need to travel nearly perpendicularly to the direction of the ultra radiation, which is contrary to experiment On the other hand, should the nature of the ultra-radiation be electronic, we are led to explain the secondary radiation as due to 'branching', that is, the collision of ultra-electrons with the electrons of the filter substance The argument against the second view is similar to that given previously In both cases, whether of wave nature or electronic, we should expect the presence of electrons the energy of which varies and reaches a maximum comparable to that of the ultra particles themselves

We might further conceive the secondary radiation to be of nuclear origin, but the principal difficulty therein is the experimental fact that the electrons emitted from paraffin, lead, and aluminium have approximately the same energy content, in addition, observations indicate that the electrons travel chiefly in the preliminary direction

Only by regarding the ultra radiation as made up of material particles such as protons with the energy of an ultra quantum, does it seem possible to interpret the secondary radiation experiments The secondary radiation corresponds to the δ rays liberated by α rays Following Rutherford, one can probably understand the energy of the accelerated electrons as corresponding to the observed range

Obituary

PROF J LORRAIN SMITH, F R S

JAMES LORRAIN SMITH was born on Aug 21, 1862, the son of the Rev Walter Smith, of Half morton, Dumfriesshire He died in Edinburgh on April 18 As an undergraduate in Edinburgh he achieved considerable distinction in philosophy, and this early training had its influence on all his subsequent work and behaviour After he took to medicine and had qualified in 1889, he spent some years working at Oxford, Cambridge, Strasbourg, and Copenhagen, mostly on physiological problems and in association with J S Haldane He then went to Belfast as lecturer and afterwards professor of pathology, in 1904 to Manchester, when the combined chair was split into pathology and bacteriology, and finally, in 1912, to Edinburgh as the first professor of pathology who had no duties as a clinical physician

Lorrain Smith was an all round pathologist and, with his own hands or through his assistants, he worked at a variety of problems He will be remembered chiefly for two investigations His early work with Haldane on hæmoglobin and its relation to carbon monoxide led to the first practicable method of determining in man the volume of the blood and the total quantity of circulating hæmoglobin In Belfast he applied this to the investigation of human anæmias, and found that in chlorosis, then common among young women, the anæmia was due to the dilution of the blood with an excess of plasma without any real deficiency in the hæmoglobin, in pernicious anæmia, on the other hand, he showed that there was a substantial shortage of hæmoglobin whether the blood volume was normal or increased This conception of the disease as a plethora was quite novel, indeed, the possibility of such a condition in man had come to be gravely doubted as the result of the failure of the attempts which had been made to establish it experimentally Why the water in the body should be distributed in such an abnormal way has never been explained, and under modern conditions the disease is practically unknown

In Manchester, Smith became interested in fats and lipoids, and, in conjunction with Mair, devised two histological methods which have been taken into general use—the Nile blue sulphate stain for neutral fats and fatty acids, and the improvement and adaptation of Weigert's bichromate hæmatoxylin process to tissue lipoids, in which he collaborated fruitfully with his chemical colleague, J F Thorpe He also did sound work on the supposed toxicity of expired air, oxygen poisoning, typhoid fever in Belfast, trench foot, and other topics

Outside his laboratory, Smith was for thirty years one of the best known and best liked figures in British pathology He took a prominent part in the foundation of the Pathological Society of Great Britain and Ireland in 1906 and of the Pathological and Bacteriological Laboratory Assistants' Association in 1912—two complementary organisations which have made a great difference to professional pathologists and their technical assistants During a period of development in which pathology passed from being an appendage of clinical medicine to an independent status, his influence was always for the good

Pathology occupies rather an awkward borderline between science and technology, some pathologists are at heart medical men, some are biologists Smith was essentially a philosopher and a biologist and he continually aimed at finding a working compromise between his outlook and the practical requirements of a sound medical education Many of us will gratefully recollect his kindly encouragement of young people and his constant friendly cheerfulness A E B

Dr T V Barker

The death of Dr T V Barker on April 15 after a short illness, at the early age of fifty years, is a serious loss to the study of crystallography in Great Britain Born in 1881, at Lytham in Lancashire, he went up from Kirkham Grammar School to Exeter College, Oxford While studying chemistry as an undergraduate, he came under the influence of Sir Henry Miers, then professor of mineralogy at Oxford, and acquired an enthusiastic love for crystals which inspired him throughout his life He also studied in Munich under Prof Groth His election to a senior demyship at Magdalen in 1905 enabled him to devote himself to research, first in Oxford and afterwards in Russia

Barker's earlier work was concerned with the regular growth, in parallel position, of crystals of numerous soluble salts upon minerals and upon one another, and with its bearing upon isomorphism and similarity of structure, and led to the recognition of the importance of molecular volume and of 'topic axes' in relation to such parallel growth Many of these results have since been confirmed by the evidence of X rays

Later on, Barker worked for a time in St Petersburg, as a pupil of Prof Fedorov, with whom he collaborated in the publication of his monumental work, "Das Kristallreich", a dictionary of the forms of all the crystals so far described, by means of which any substance included in it might be recognised from the measurement of its crystals ('crystallochemical analysis') The method was, however, complicated and required an amount of specialised knowledge which prevented its general use, and after his return to Oxford in 1909, Barker devoted his attention to devising a simpler method of classification His book, "Systematic Crystallography", published last year, described the principles on which he proposed that a new dictionary of the crystal kingdom should be constructed, and it is much to be regretted that he did not live to supervise the execution of his project In this connexion he also published, in 1922, a book on "Graphical and Tabular Methods in Crystallography", with the view of simplifying and shortening the operations of measuring and describing crystal forms

At Oxford, Barker was successively demonstrator in mineralogy and University lecturer, and afterwards reader, in chemical crystallography, while he held a research fellowship at Brasenose College His lectures and classes did much to encourage the study of crystals among undergraduates, and he also endeavoured, by vacation courses to schoolmasters, to awaken an interest in the subject in schools During the last few years he had been led to take up administrative work, and since 1929 the increasing work of the University Chest, of which he had become secretary, had claimed his whole time He will be greatly missed on many University boards, as well as by his many scientific friends and colleagues in Oxford and elsewhere H L B

We regret to announce the following deaths

Dr Thomas Ashby, who was director of the British School at Rome from 1906 until 1925, and an authority on the archæology of Rome, aged fifty seven years

Prof J E Edwards, principal and professor of mathematics and physics at Queen's College, London, author of well known text books on the calculus, on May 16, aged seventy seven years

Prof T R Glynn, emeritus professor of medicine in the University of Liverpool, on May 12, aged ninety years

Lieut Col H T Morshead, Director of the Burma Circle, Survey of India, who was a member of the expeditions to Mount Everest in 1921 and 1922, on May 17, aged forty eight years

Mr F P Sprent, assistant keeper of printed books in the British Museum and author of many works on cartography, on May 16, aged forty-six years

News and Views.

The Prime Minister's announcement in Parliament upon the future policy of airship development gave little cause for surprise, and must presumably be received in the spirit of half a loaf being better than none The Government was faced with three courses of action (1) To continue on a programme of new ships, carrying on the development as experience dictates, (2) to cease entirely, disposing of *R100*, turning the Cardington works to other uses, and terminating our responsibilities to the authorities who erected the various colonial mooring masts as best we can, (3) to recondition the existing airship, and find sufficient money to allow a limited experimentation to proceed along lines that the Simon inquiry and the Aeronautical Research Committee have suggested The Government has chosen the last course, stating that it hopes that the use of the ship will serve to supplement the model experiments already made, will keep together a small nucleus of trained men, and will add its quota to the relieving of the local unemployment problem It is estimated that sums of £120,000, £130,000, and £140,000 should be sufficient for this during the next three financial years It is hoped that the various Governments concerned will agree to maintain their own airship stations where in existence

So far as it goes, there can be no objection to this scheme, but it is obvious that neither in the Prime Minister's statement nor the subsequent debate is there any recognition of the fact that there is any necessity to ensure the continuation of scientific thought upon the broad problems of future development That a select company of airship builders and operators will be maintained was stressed several times, but the fact that without a new building programme there will be no design staff kept together appears to have been entirely overlooked It is an open secret that the designers of both of the ships have already been practically dispersed, owing to the lack

of continuity in the building programme, and this further three years' interval will certainly serve to set the seal upon this unfortunate state of affairs Further, a suggestion that a scientific airship man should sit upon the Air Council in order to preserve contact with the experimenters at Cardington, and so keep the broader outlook of policy alive, was received by the Under Secretary of State for Air with the remarkable statement that "It is rarely the case that a scientific expert is an efficient administrator" Mr Montagu's opinion is singularly at variance with that of the rest of the aeronautical world It is no mere polite phrase, but a literal fact, that admiration of the administration of aeronautical scientific research in Great Britain is world wide Mr Montagu should make use of a press cutting agency, or even maintain a closer personal touch with the scientific men in his own departments

A LECTURE upon a type of airship that does not need gasbags and fabric envelope was given by Mr Carl Fritsche, president of the Aircraft Corporation of Detroit, before the Royal Aeronautical Society on May 14 This company has already built, and operated for two years, a small 'metal clad' airship of 202,200 cubic feet capacity, which carried a useful load of 1300 lb, in addition to fuel, oil, ballast, etc, at 70 miles per hour top speed It is filled with helium and has a remarkably low diffusion loss of only 12 lb of lift for every twenty four hours This is principally due to the impermeability of the metal skin, the use of which is made possible by a special system of riveting the joints, which is really an ingenious adaptation of the principle of sewing with wire This not only makes a gas tight joint possible, but very considerably reduces the labour and time needed for erection Compared with *R100*, using helium, a metal clad ship could carry an estimated load of 10,000 lb more, with 600 h p less in engine power A part of the lecture was devoted to a detailed estimation of the costs of working an Atlantic service with these airships Given a passenger fare of £180 and a mail subvention of £2 8*s* per mile, it was suggested that an air line could be run at a profit of twenty per cent a year This was provisional upon the ships being built and operated by an international company, with sufficient freedom from political restrictions to allow them to utilise their carrying capacity to the best advantage

THE Annual Report of the Council of Management presented to the members of the British Science Guild at the general meeting on May 12 illustrates the unique place occupied by the Guild in the national life of Great Britain, and the valuable services it is rendering in promoting effective contact between science and the general life of the community The value of the "Catalogue of British Scientific and Technical Books" prepared by the Guild is best attested by the publication of a third edition in September 1930 Its educational work is represented by the Norman Lockyer Lecture on "Science and Modern Industry", delivered by Sir William Pope, and the Alexander Pedler lecture on "Science Discipline", delivered by Lieut Col Sir David Prain, both of which received wide notice in the press Changes of officers during the year are recorded in the resignations of Lieut-Col W A J O'Meara from the office of hon secretary, and of Sir John Young from the chairmanship of the finance committee, and the appointment of Major A G Church as organising secretary

A VALUABLE result of the non political and national structure of the Guild is its ability to make authoritative representations on matters of public interest in which scientific considerations are involved Two instances of such representations are referred to in the Report, the first being the Memorandum of Evidence submitted by the Guild in June 1930 to the Royal Commission on the Civil Service The memorandum, which is printed in full in the Report, stresses the importance of the technical factor in many modern problems, and urges the necessity of remodelling the organisation of departments of State on the type adopted in progressive industrial concerns The Guild considers that the time is ripe for a simplified structure of the technical services, and the memorandum enunciates the principles essential for efficient administration, and urges that the heads of the larger and more important professional, scientific, and technical departments should be given full administrative status The chief defect in the organisation and structure of the Civil Service lies in the dominant influence of officers of the administrative and clerical groups An appendix to the memorandum outlines the factors responsible for the present unsatisfactory position of the 'expert' group in the Civil Service In January 1931, the Council of the Guild adopted an exhaustive report on the scientific and professional staffs in the public services and industry, which has been widely circulated and to which statement the non political and representative character of the Guild lends great authority The report is dealt with in our leading article this week

IN his presidential address to members of the Guild at the annual meeting, the Right Hon Sir Samuel Hoare, M P, referred to the more ambitious programme upon which the Guild is anxious to embark In additon to the contemplated investigation of the potentialities of existing industries and the effect of the proper application of science upon them, which would indicate how far reactionary influences, either of Government, employers, or trade unions, are impeding development, Sir Samuel Hoare urged the importance of a scientific study of the disarmament question The main problem of disarmament, and by far the most difficult, is that of the new weapons of warfare and the method of their control The relation of science and the attitude of scientific workers to gas warfare and other new forms of warfare require investigation by men of science as well as by politicians and the general staffs Politicians in particular need a scientific opinion upon these subjects for the Geneva Conference in 1932 If during the next six months the Guild can produce a report upon such questions, it will be doing most useful work in educating public opinion and in investigating a critical aspect of the most prominent question in foreign politics in the immediate future

THE philosophical faculty of the University of Berlin has conferred upon Prof R W Wood, of the Johns Hopkins University, Baltimore, the degree of Doctor of Philosophy (*honoris causa*) This is the highest honour which the faculty has in its power to give, and is a recognition of Prof Wood's contributions to physical optics In announcing the award, Prof Jaeger, the dean of the faculty, singled out as of particular importance Prof Wood's researches on the resonance radiation of gases and vapours These have certainly called for the exercise of the utmost experimental skill, and although initially conceived and carried out at a time when our knowledge of the structure of atoms and molecules was practically nothing by current standards, have contributed in no small degree, and continue to contribute, to our present ideas on "the exact nature of the piece of machinery which we call the molecule", to use Prof Wood's own words With the study of resonance radiation, however, one is tempted to associate Prof Wood's allied work on magneto optics, and to quote as an example of his ingenuity the separation of the *D* lines of sodium for work with intense beams of monochromatic light by the difference in their rotations More recently, Prof Wood has been interested in the Raman effect, where he has devised methods for reducing the time of exposure needed for recording the feeble spectra of modified radiation, and has also developed rapid methods for measuring up the Raman spectra In addition to his many experimental contributions to physical optics, Prof Wood is the author of two books on the subject, and has ruled gratings for other laboratories His work, although, naturally, carried out on rather different lines, is in every sense worthy of being ranked with that of Rowland and of Michelson

IN his second Rhodes Memorial Lecture, delivered at Oxford on May 16, Prof A Einstein discussed the application of the field equations of the theory of relativity to the problem of cosmogony When the general theory of relativity was first formulated, the universe was assumed to be of a definite size, and in order to make the field equations compatible with this assumption an arbitrary term was introduced Subsequent investigation has shown that even with this arbitrary term, the size of the universe could only remain constant under special assumptions—in general it would vary with the time The work of Hubble on the radial motion of the extra galactic nebulæ has shown that these systems of stars, distributed approximately uniformly throughout space, are all moving at very high speeds, which increase linearly with the distance Prof Einstein now omits the above mentioned arbitrary term, and his original equations lead to a rate of expansion which is related by a simple formula to the mean density of matter in the space under consideration The rate of recession observed by Hubble appears to agree approximately with the rate calculated from the formula if one assumes the density to be of the order of magnitude which appears to exist in the universe as we know it The main difficulties are the small value of the world radius (one hundred million light years), the comparatively short period of some ten thousand million years during which the space structure can have been expanding, and the conditions in the early stages before expansion had taken place Prof Einstein's next and final lecture on the latest developments of the theory will be given on May 23 at 12 noon, when the University will confer on him the honorary degree of D Sc

NEWS from the British Arctic Air Route Expedition, published in dispatches in the *Times*, shows that the main features of its work have been accomplished, happily without the loss of life that was at one time feared Last August, a meteorological station was founded on the Greenland ice sheet in lat 67° 3′ N, long 41° 48′ W, at an elevation of 8000 feet, about one hundred and forty miles north west of the expedition's base on Sermelik Fjord near Angmagsalik The station was merely a double canvas tent, since transport difficulties precluded a more substantial building Two men occupied the station until Oct 2, when they were relieved by two others On Dec 3 another relief party reached them, and it was then proposed to abandon the station, owing to the severity of the blizzards and the difficulty in sledging up sufficient food from the base Mr A Courtauld, however, offered to remain alone, in order to continue the important observations throughout the winter He was left with ample provisions to last until May Efforts to relieve him in the early spring failed Wireless messages to this effect reached Europe and caused anxiety and eventually alarm, which, however, was not felt at the expedition's base The Swedish airman Capt Ahrenberg made a fine flight from Europe to the rescue, and, reaching the station on the ice cap, found it deserted Mr H G Watkins with a sledge party from the base had reached it on May 5, and found Mr Courtauld safe and well, with ample food supplies On May 13 they were back at Sermelik Fjord The observations at the high level station are the first complete winter records from the interior of Greenland and should prove of great value

THE German Expedition to Greenland has sent to the *Times* a dispatch which seems to leave no doubt that its leader, Dr A Wegener, has perished on the ice cap This expedition, with its base near the Kamarujak glacier on the west coast, also placed a station in the interior The German station was in lat 71° 8′ N, long 40° W, which is about the middle of Greenland, 275 miles north of the British station It was set up last summer and inhabited by three men, Drs Georgi, Sorge, and Loewe, who were found safe on relief reaching them on May 7 It was then learned that Dr Wegener with one Greenlander had left the station on Nov 1 in an attempt to return to the base, which, however, he never reached The journey entailed a march of about three hundred miles, and though there appear to have been depots on the route, the risks entailed in winter darkness and blizzards were very considerable The German expedition used motor sledges as well as dog teams in travelling over the ice sheet, and while the mechanical transport proved satisfactory, reliance was placed

mainly on the dogs This station will provide another set of most important meteorological observations

THE subject of the Friday evening discourse at the Royal Institution by Prof J C Philip, on May 15, was "Experimental Aspects of Hydrogen Ion Concentration" Prof Philip pointed out that the contrast between solutions of strong and weak acids of the same total acidity is very marked These differences are determined by the degree of ionisation mainly, and in the case of a weak acid like acetic acid a distinction must be drawn between 'total' and 'effective' acidity, the latter quantity being measured by the hydrogen ion concentration and expressed in terms of the pH value (Sørensen) Besides the standard electrometric methods of determining hydrogen ion concentration, now being developed in the direction of continuous record and automatic control, the colorimetric method is found valuable in many cases The fact that for different indicators the colour changes occur at quite different pH values, and that the colour change in any particular case is not absolutely sharp but takes place gradually over a limited pH range, underlies the practical use of the colorimetric method It is assumed that two solutions which exhibit a colour match (for the same amount of indicator) have the same pH value In reality this principle is subject to some qualification A significant point that emerges from the study of hydrogen ion concentration is the extent to which the pH value of a weak acid is altered by the addition of a neutral salt of the acid Solutions which contain a weak acid in presence of its neutral salt have, moreover, a remarkably steady pH value, which is altered to a relatively slight extent by the addition of acid or alkali Because of the resistance which they offer to change of acidity, mixtures of this kind are termed 'buffer' solutions They play an important part in the accurate determination of pH values and the 'buffer' effect is of prime significance in the regulation of the hydrogen ion concentration of the blood

ON May 14 a discourse was given by Mr Sydney Evershed before the Institution of Electrical Engineers to commemorate the centenary of the birth of David Hughes The fame of Hughes rests on two works of creative genius the invention of the synchronous type printing telegraph and the discovery of the microphone Hughes was the grandson of a bootmaker at Bala, in North Wales He was born in London, but his family emigrated to the United States in 1838 He picked up some knowledge of electricity and at the age of twenty four completed the development of his printing telegraph It rapidly came into use in the United States and France, but England was almost the last civilised country to adopt it The success of his invention brought Hughes a large fortune and in 1875 he returned to England and made London his home Having leisure for research, he engaged in experiments which led to the discovery of the microphone Graham Bell solved the problem of the transmission and reproduction of speech, but some kind of relay was needed for large telephone systems This was found in the action of sound waves on the contact of electrical conductors Having discovered the full scope of the phenomena, Hughes gave his knowledge freely to the world in a paper read to the Royal Society on May 8, 1878 In this paper, Hughes gave the name 'microphone' to any device in which sound waves acted on electrical contacts From that day to this, every instrument employed as the transmitter for a telephone system has embodied some form of Hughes's microphone to serve as a relay He was a fellow of the Royal Society and a president of the Institution of Electrical Engineers

STANDARDISATION in the domain of chemical industry has moved a step forward with the inaugural meeting on May 7 of the provisional council for the chemical division of the proposed Standards Association of Great Britain Negotiations, having in view an extension to other fields of the good work done by the British Engineering Standards Association, have been proceeding actively and harmoniously during the past year, with the result that agreement has been reached on a comprehensive scheme of organisation The general council of the new body will be constituted by the election of nine members from each of the divisions and by the nomination of a representative each of the Board of Trade, the Department of Scientific and Industrial Research, the Federation of British Industries the Association of British Chambers of Commerce and the Institution of Civil Engineers There will be four co equal and largely autonomous main divisions, each controlled by a divisional council, for engineering, chemistry, building, and textiles The engineering division will consist of the present B E S A, with the exception of those elements which will now find a more appropriate place under one of the other divisions The council of the chemical division will consist of not more than 40 members, not more than five places being reserved for the co option of individuals whose services are likely to be of special assistance to the council Agreement has been reached regarding the nominating bodies, each of which will nominate one member, with the exception of the Association of British Chemical Manufacturers, which will have five representatives Dr E F Armstrong has been elected chairman, and Mr W Rintoul vice chairman The council itself will not undertake the specification of standards, but will utilise existing organisations which are already engaged in that work Where necessary *ad hoc* technical committees representing the main interest affected will be constituted

ON May 11, the Manchester and Altrincham Railway was changed over to all electric operation, after eighty years of steam working Although only twenty-eight miles of track, including sidings, are involved, it is of interest, as it is the first railway in Great Britain electrified on the standard 1500 volts direct current system adopted by the Ministry of Transport Its power is obtained from the Stretford Electricity Board at 11,000 volts three phase The 11,000 volt cables are in duplicate and are carried on wooden stumps along the tracks The district served is densely populated and so an accelerated service and more stations were

required Transformers are used at the substations to step down the high pressure power to rotary converters which transform the alternating into direct current By means of a pantograph, each set of two series connected 750-volt direct current motors in the coaches is connected between the overhead wires and the return rails To make the load more uniform and furnish a reserve of power, a battery of accumulators is installed at each substation The machines and switchgear at the substations are kept free from dust and dirt by combined vacuum cleaning and blowing apparatus There is one steel tank mercury arc rectifier for 1500-volt working at one of the substations This type of rectifier will probably be widely used in the future It was designed and manufactured by a British firm It is a twelve-anode machine and so the ripple in the direct current voltage is very small In order to prevent possible interference with telephone circuits, a smoothing circuit is provided This consists of a reactance coil on the direct current side and four resonant shunt circuits connected across the direct current load Experience with rotary converters has proved that this device is very efficient

IT is announced by Science Service, Washington, D C, that Dr William Wallace Campbell, director of the Lick Observatory and formerly president of the University of California, has been elected president of the National Academy of Sciences, in succession to Dr T H Morgan, of the California Institute of Technology, Pasadena Dr Campbell established his place in American science principally through his work in spectroscopic astronomy, he has also done notable work in solar eclipse problems He was born in Ohio in 1862, and went to Mt Hamilton as astronomer at Lick Observatory in 1891 In 1901 he was made director of the Observatory, and in 1923 president of the University of California He retired from the latter post recently, in order to return to active astronomical work Dr David White, of the U S Geological Survey, formerly home secretary of National Academy, has been elected vice president, and Dr Fred E Wright, of the Carnegie Institution of Washington, formerly vice president, has become home secretary Dr Peter Debye, the distinguished physicist of the University of Leipzig, has been made a foreign associate of the Academy, and the following new members were elected Henry Bryant Bigelow, Museum of Comparative Zoology, Cambridge, Mass (oceanography), Edwin Broun Fred, University of Wisconsin, Madison, Wis (bacteriology), Edwin Crawford Kemble, Harvard University, Cambridge, Mass (physics), Adolph Knopf, Yale University, New Haven, Conn (geology), Robert Harry Lowie, University of California, Berkeley, Calif (anthropology), Joseph Haines Moore, Lick Observatory, Mt Hamilton, Calif (astronomy), Robert Lee Moore, Austin, Texas (mathematics), Hermann Joseph Muller, University of Texas, Austin, Texas (genetics), George Linius Streeter, Department of Embryology, Carnegie Institution, Baltimore, Md (embryology), Margaret Floy Washburn, Vassar College, Poughkeepsie, N Y (psychology)

THE second general assembly of the International Union for the Scientific Investigation of Population Problems (chairman, Prof Raymond Pearl) will be held in London on June 15–18, at the house of the Royal Society of Arts, John Street, Adelphi, Strand, W C 2 Most of the European Powers and also the United States of America will be represented at the meeting The first three morning sessions will be devoted to official business, and the afternoon sessions and the whole of June 18 to reports and papers relating to the work of the Union Commission 1 (population and food supply) reports on the first afternoon, Commission 2 (differential fertility) on the second afternoon, and Commission 3 (vital statistics of primitive races) on the third afternoon The papers also to be read on these afternoons and those for Thursday, June 18, include studies on differential fertility in Stockholm, the birth-rate and population of the United States, and vital aspects of a Chinese family population during six hundred years, more general papers on population theory and human biology, and experimental work on mice populations Scientific workers are invited to attend the afternoon sessions and those on June 18 The organising committee for the meeting is the British Population Society, of which the chairman is Sir Bernard Mallet, and honorary secretary, Mr Eldon Moore, Eliot Vale House, Blackheath, Kent, from whom tickets can be obtained

A FEW months ago (Jan 31, p 176) we announced in these columns that arrangements were being made by the Society for Cultural Relations for a tour of British scientific workers to the U S S R Owing to the large demand for membership of the first party, the list for which closed on April 30, a second party will now leave London Bridge by Soviet ship for Leningrad on Aug 8, returning to London about Sept 2 in time for the British Association meeting The return fare will be £18 0*s* 0*d* The party will spend a total of sixteen days in Russia, and the cost per day will be £1 0*s* 0*d* per head inclusive Meetings are to be arranged which members of the party will be invited to address, and there will be excursions with guides to scientific institutions of interest to the members The party will consist of twenty five persons If there is a large demand for places, the list might be extended The latest date for receiving applications is June 15 Applications and all inquiries should be addressed to the Secretary, Society for Cultural Relations, 1 Montague St, London, W C 1

A CONFERENCE of agricultural and rural bodies met at the Ministry of Agriculture on May 13 to consider the damage caused by grey squirrels in Great Britain Mr A D Middleton, of the University Museums, Oxford, a summary of whose recent paper on the distribution and habits of the grey squirrel appeared in NATURE of April 4, p 540, reported the results of his investigations, and Mr L W Swainson, honorary secretary of the Anti-Grey Squirrel Campaign, described the activities of that body The conference passed a resolution expressing the opinion that the grey squirrel is a pest which causes extensive damage

to agriculture and horticulture, that it is widespread and increasing in numbers, and that it is in the interests of agriculture and horticulture that all possible steps should be taken to bring to the public notice the damage caused by these animals and the importance of repressing them. The Ministry of Agriculture was asked to issue an educational pamphlet on the grey squirrel, describing its life history and giving methods for its destruction, to be distributed to rural organisations with the view of encouraging the destruction of the pest.

THE Court of Common Council of the City of London has made a donation of two hundred and fifty guineas to the funds of the British Empire Cancer Campaign.

THE Honorary Gold Medal of the Royal College of Surgeons has been conferred on Mr. G. Buckston Browne, in recognition of his valuable contributions to the surgery of the genito-urinary system, and of his great liberality in the endowment of an institution for surgical research.

ON Feb. 10, Dr. Joaquim de Sampaio Ferraz resigned, for reasons of health, from his post as director of the Brazilian Meteorological Institute, which he initiated in 1921. Although he has retired from his official position, he intends to carry on his work in collaboration with M. Paul Pires Xavier, who has been appointed to succeed him.

THE portrait of Dr. G. Claridge Druce which was subscribed for by members of the Botanical Society and Exchange Club of the British Isles on the occasion of his eightieth birthday on May 23, 1930, has been painted at his residence, Yardley Lodge, Oxford, by Mr. P. A. de Laszlo. It will be formally presented to Dr. Druce at Mr. de Laszlo's residence in Fitzjohn's Avenue, London, next month.

AT the anniversary meeting of the Royal Society of South Africa, held on Mar. 18, a resolution was moved by Prof. Morrison and seconded by Prof. Newbery asking the Council to protest against the drastic reduction in the government grant to the Society for 1931. The following were elected as officers of the Society for the year 1931: *President*, Dr. W. A. Jolly; *Honorary Treasurer*, Dr. L. Crawford; *Honorary General Secretary*, Dr. B. F. J. Schonland.

PROF. I. E. TAMM, of the Physics Research Institute and professor of physics in the First University of Moscow, will speak on "Higher Education in Soviet Russia", at a meeting of the Society for Cultural Relations between the People of the British Commonwealth and the U.S.S.R., to be held on May 28. Further information concerning the meeting can be obtained from the Secretary, S.C.R., 1 Montague Street, London, W.C.1.

THE council of the Institution of Electrical Engineers has made the following award of premiums for papers read during the session 1930–31, or accepted for publication: the Institution premium to Commendatore G. Bianchi, Ayrton premium to R. Grierson, John Hopkinson premium to J. W. Rissik and H. Rissik, Kelvin premium to B. L. Goodlet, F. S. Edwards and F. R. Perry, Paris premium to P. J. Ryle, and extra premiums to W. E. M. Ayres, R. M. Charley, H. S. Carnegie, D. B. Hoseason, Dr. J. J. Rudra and Prof. Miles Walker, Prof. W. Cramp and A. P. Jarvis, P. J. Higgs, J. C. Prescott and E. W. Connon, G. G. Small, R. J. Brooksbank, and Prof. W. M. Thornton, Prof. S. P. Smith, and Prof. E. Wilson. In the Wireless Section, the Duddell premium has been awarded to T. Walmsley and extra premiums to C. E. Horton and C. E. Rickard. In the Meter and Instrument Section the Silvanus Thompson premium has been awarded to Prof. W. M. Thornton, M. Waters, and W. G. Thompson, and an extra premium to E. W. Hill and G. F. Shotter.

THE Secretary of State for Scotland has appointed Dr. Birkett Wylam to be Chief Inspector for Scotland under the Alkali, etc., Works Regulation Act and Inspector under the Rivers Pollution Prevention Acts, in succession to Mr. J. W. Young, who is retiring. Dr. Wylam, who enters on his duties on June 1, is a graduate of the University of Durham. On graduation as B.Sc. he obtained the Freire Marreco medal for practical organic chemistry and was engaged on post-graduate research work for two years. Since 1928 he has been working as research chemist, and latterly also as process manager, in works connected with Scottish Dyes, Ltd.

WE learn from the recent issue of the *Taylor Hobson Outlook* that the alteration in size or scale of the projected cinematograph image, seeing that the relative positions of the film, the projecting lens, and the screen are fixed, is effected by a change in the lens. To enlarge the image, the focal length of the lens must be reduced, and this is effected by making the front and back components movable axially and causing them to approach each other. To maintain the sharpness of the image, that is, to keep the film and the screen in focus during the change, the relative rates of movement have to be adjusted with great accuracy.

WE are glad to see that the Royal Photographic Society is giving rather more attention in its *Journal* to the scientific and technical side of photography than it has for the last few years. The April number of its journal has a 56-page supplement which consists of articles on the physical aspects of the latent image, the applications of physical chemistry to photography, recent progress in optics, photo-engraving, cinematography, colour photography, and commercial photography. This number also includes the eighth Hurter and Driffield memorial lecture by Sir William Bragg, on "X-rays and the New Range of Vision". In December, a special cinematograph number will be published, and other special numbers will be issued from time to time. The journal is published by the Fountain Press, 14 Clifford's Inn, at 2*s*. 6*d*. per copy.

THE latest issue of the Classified List of Publications of the Carnegie Institution of Washington (April 1931, 208 pages) contains a chronological list arranged under authors' names, a classified list, with summaries of the contents of papers, grouped under the appropriate branch of science, and an index of authors. Copies of the publications, sent gratuitously to a carefully

selected list of libraries throughout the world, may be consulted there, but books not otherwise disposed of are for sale at prices approximating to the cost of publication Correspondents may obtain price lists, or classified lists, as issued, by furnishing requisite addresses to the Secretary, Carnegie Institution of Washington It is unnecessary to stress the value of the publications in the various branches of science and letters issued by the Institution

Two books are nearly ready for publication by Messrs George Allen and Unwin, Ltd , which should be of general scientific interest namely, "The Universe in the Light of Modern Physics", by Prof Max Planck, translated by W H Johnston and "Human Heredity" by Profs E Bawe, E Fischer and F Lenz translated by Eden and Cedar Paul

Messrs Dulau and Co , Ltd , 32 Old Bond Street, W 1 have just issued Catalogue No 185—' Fungi, Plant Pathology, etc "—comprising a thousand works from the library of the late Dr N Patouillard Among the volumes offered for sale are Saccardo's "Sylloge Fungorum" Saccardo's Fungi Italici", Boudier's "Icones Mycologicae", Fries' "Icones Selectae Hymenomycetum ', Paulet's "Iconographie des Champignons" and Lucand's 'Suites a Bulliard Messrs Dulau have also circulated a list (No 186) of upwards of 600 volumes, mainly on natural history, now on sale at very low prices

Applications are invited for the following appointments, on or before the dates mentioned - Two full time tutors in the department of adult education of the University College of Hull—The Registrar, University College, Hull (May 26) An assistant lecturer in mathematics at Westfield College—The Principal, Westfield College, N W 3 (May 27) A teacher of science and engineering at the Coleraine Technical School—The Principal, Technical School, Coleraine (May 28) A vice principal of the Somerset Farm Institute, Cannington, near Bridgwater—The Clerk of the Somerset County Council, Ashcombe House, Weston super Mare (May 30) A chief cataloguer in the Library of the University of Aberdeen—The Secretary, University, Aberdeen (June 4) A resident assistant pathologist at the Royal Free Hospital and London (R F H) School of Medicine for Women— The Secretary, Royal Free Hospital, W C 1, or the Warden and Secretary, London (R F H) School of Medicine for Women, W C 1 (June 5) A secretary of the University Chest of the University of Oxford—The Acting Secretary, University Chest Office, Oxford (June 6) An assistant lecturer in philosophy at the University College of Swansea The Registrar, University College, Singleton Park, Swansea (June 6) A professor of mathematics at Raffles College, Singapore—The Director of Recruitment, Colonial Office, 2 Richmond Terrace, Whitehall, S W 1 A physics mistress at Westonbirt School, Tetbury— The Headmistress, Westonbirt School, Tetbury, Glos A head of the mathematics department of the Borough Polytechnic—The Principal, Borough Polytechnic, Borough Road, S E 1 A laboratory assistant at the County Mental Hospital, Lancaster—The Medical Superintendent County Mental Hospital Lancaster

Our Astronomical Column

The Date of the Crucifixion – *Astr Nach* 5784 contains a paper on this subject by E Dittrich He makes use of data from the writings of the late C Schoch, both published and unpublished These include a discussion of the total eclipse of the sun of Nov 24 in A D 29 Some ancient writers attempted to explain the darkness mentioned at the Crucifixion by this eclipse The explanation is, of course, impossible, for the double reason that the Passover comes near the spring equinox and also near the full moon Still the statement has some value, for it would scarcely have been made unless the year of the eclipse agreed with that of the Crucifixion or came very near it The track of totality was investigated by Schoch, who found that it ran just north of Palestine, the maximum phase at Jerusalem was 11½ digits and occurred 12 minutes before local noon An argument is based on the incident of the corn being ripe enough to eat the ears at a time a little before the Crucifixion The Passover must have been rather late the preceding year having an intercalary month at the end of it In summing up, the author observes that the discussions of the last hundred years have greatly narrowed the possible range of dates The range was originally about ten years, but has now been reduced to two , there is almost universal agreement that it was either A D 29 or 30

Temperatures in Sunspots —In the *Scientific American* for April, Prof H N Russell gives an account of recent work on sunspot temperatures carried out at Mt Wilson by Pettit and Nicholson with the aid of a delicate vacuum thermocouple In violet radiations, the spot gave less than 30 per cent of the disc, but in the red the proportion was 40 per cent and in the extreme infra red it reached 80 per cent A mean was taken as 47 per cent, which was reduced to 40 per cent when the scattering of sunlight by the atmosphere was allowed for This gave 4750° C measured from the absolute zero about 1200° cooler than the general surface temperature The cooling is ascribed to the rapid expansion which the gas undergoes on ascending from a lower region of higher pressure This implies that the portions of sunspots that are accessible to study are quite shallow , but an explanation, due to Unsold, is given, suggesting that the mechanism producing the spot is much deeper, about 1000 miles down , the hydrogen atoms are there ionised, but as the column ascends, recombination of protons and electrons liberates enough heat to maintain the vertical current, which, as stated above, is cooled by expansion on reaching the surface

Catalogue of Stellar Parallaxes —*Publication* No 4 of Merate Observatory is a general catalogue of 3975 stellar parallaxes compiled by Gino Cecchini It includes trigonometrical parallaxes determined at all the leading observatories, also dynamical, hypothetical, group, and Cepheid parallaxes, distinguished by different symbols The catalogue gives approximate R A and Decl for 1900, magnitude, spectral type, parallax, probable error (each given to 0 001″), absolute magnitude, proper motion in polar co ordinates, and references to Boss, Cincinnati, and Draper Catalogues Proxima Centauri is entered as type *M*, parallax 0 780″ ± 0 006″, absolute magnitude 15, proper motion 3 76″ in P A 283° Notes and references follow the catalogue, the whole making a useful work of reference

Research Items

Peking Man: Geological and Palæontological Evidence.—An account of the discovery of Peking man is contributed by P. Teilhard du Chardin to *L'Anthropologie*, t. 41, pts. 1-2, which deals in some detail with the geology and palæontology of the cave of Chou Kou Tien. It is evident that the cave was not an open fissure in which the remains were carried by torrential action, as was at one time thought, but a true cave which was gradually filled by a succession of deposits. The nature of these deposits points unquestionably to the fact that the cave was the habitation of carnivores, and presumably of man. It presents analogies with the caves of Europe, but the evidence of stratigraphy and palæontology points to the far greater antiquity of the levels in which human remains have been found. Hitherto only one pleistocene formation had been recognised in China, that of the yellow loess characterised by *Rhinoceros tichorhinus*, *Bos primigenius*, *Cervus elaphus*, *Hyæna crocuta*, etc., and worked quartzites of Mousterian and Aurignacian type. Now, however, it is evident that beneath the loess deposit of the Upper and Middle Pleistocene, and hitherto confused with it, is a series of sands, clays, and reddish loess representing a distinct formation with a characteristic fauna, *Rhinoceros cf. sinensis*, *Hyæna sinensis*, *H. machairodus*, etc. This formation begins at the end of the tertiary and the beginning of the lower quaternary. It is to this Early Pleistocene that the fossiliferous deposits of Chou Kou Tien belong. On this point the palæontological evidence is decisive. No fossil characteristic of the yellow loess has been found at Chou Kou Tien, the fauna of which corresponds with the pleistocene fauna of the Nihowan deposits, yet is lacking in those forms which assign the latter to the tertiary. In the rhinoceros, hyæna, horse, *Canis sinensis*, *Machairodus*, there is exact correspondence.

A New Classification of Mammals.—In the course of arranging a large collection of mammal skins for cataloguing, storage, exhibition, and teaching, George Gaylord Simpson found it necessary to compile a workable synthesis of recent taxonomic studies of mammals. This classification of the living and extinct forms is now published for the use of workers faced with the same problems (*Bull. Amer. Mus. Nat. Hist.*, vol. 59, p. 259; 1931). The classification is conservative; it follows a middle course between the 'splitters' and the 'lumpers', but, as it is, it summarises the progress of the last half century. Where Gill's work of 1872 contained 138 families, of which 33 were extinct and 105 living, the present classification contains 242 families, 129 extinct and 113 living. It is clear that the progress of the intervening years as regards numbers of families has been due almost entirely to palæontological discovery, and that although many new species of living mammals have been described, their discovery has added little to the broader taxonomy of the class. So also with the changes in arrangement and classification: comparative anatomy of recent mammals has made its proper contributions, but the discovery of their extinct ancestors has added much more. The discrepancy between the two sets of contributions is likely to increase, for while outstanding new discoveries are extremely rare in the modern groups, the rate of palæontological discovery tends to increase rather than diminish.

Nutrition of Mosquitoes.—In the *Transactions of the Royal Society of Tropical Medicine and Hygiene*, vol. 24, pp. 465-472 (January 1931), Malcolm E. Macgregor describes some experiments dealing with the food requirements of mosquitoes with respect to ovulation. Two species were chiefly used in these experiments, namely, *Ædes ægypti* and *Culex pipiens*. The author points out that mosquitoes betray two methods of feeding. In the method usually known as 'biting' (or its equivalent, which can be attained by feeding from capillary tubes when the proboscis is unsheathed') the insect is able to draw the ingested food directly into the stomach. In the other method, known as 'discontinuous suction', the ingested food collects first in the diverticula. The function of the diverticula as food reservoirs has long been recognised, and the author finds that the gas contained therein is air, and that these organs have a dual function. Besides acting as food reservoirs they serve as air separators in which 'air locks', between discontinuous sections of fluid food, are separated in order to preclude the entrance of air into the stomach. A selective and voluntary control is exercised by the insects in regard to the aspiration and destination of ingested foods, blood being generally dispatched to the stomach and sugary solutions to the diverticula. The outcome of the experiments described indicates that the essential requirements for ovulation in *A. ægypti* are not only the presence of sperms in the spermatheca, but also the direct reception by the stomach of some essential food (blood). In the case of *C. pipiens* an additional factor, as yet undetermined, is necessary. If unfertilised females of *A. ægypti* take blood by interrupted feeds into the diverticula, ovulation never occurs. If, on the other hand, the blood enters the stomach, activation of the ovaries and oviposition usually take place. When a fertilised female of either species is fed through a capillary tube on blood containing a trace of honey, or other carbohydrate, the blood-honey mixture is diverted into the diverticula, and the food is rapidly digested without any activation of the ovaries.

Apple Scab.—Two papers dealing with work carried out at the Long Ashton Research Station upon this fungus disease of apples, *Venturia inæqualis*, appear in the March issue of the *Journal of Pomology and Horticultural Science* (vol. 9, No. 1). Dr. K. H. Johnstone analyses the varying resistance shown by different varieties of apple to the disease. The importance of an adequate water supply for spore germination of the parasite is emphasised, and it is pointed out that, in this connexion, varietal differences in the ease of wetting of the cuticle surface of the host may be important. Actual thickness of the cuticle presents no barrier to penetration, but in certain varieties an impenetrable quality appears to develop, so that the period of susceptibility is of short duration in these varieties. R. W. Marsh describes lime sulphur spraying experiments carried out on commercial plantations in Somerset, Worcestershire, and Herefordshire to test the conclusion, based on Long Ashton experience, that excellent control could be obtained by spray applications terminating before the time that the flower petals fall. The results were satisfactory on the whole, and, incidentally, observations on spore deposition carried out during these trials suggest that almost all the new infection in the early season comes from pustules from scabbed leaves, not from over-wintered leaves, as had been stated to be the American experience by Keitt and Jones (*Wisconsin Agric. Expt. Station Res. Bull.*, 73, 1926).

The Gold-Belt of Rhodesia.—"The Geology of the Country between Gatooma and Battlefields", in

Southern Rhodesia, is described by A M Macgregor in *Bull* 17 of the Geological Survey of Southern Rhodesia, 1930, pp 144 and maps The area forms the central part of the principal gold belt of Rhodesia and lies between the largest mines of the Colony, the Cam and Motor in the north, and the Globe and Phœnix and Gaika in the south The most ancient rocks are green stones with interbedded sediments that are older than the Rhodesdale Gneissic Granite Next follows a belt of sedimentary rocks which in turn are cut by a series of 'younger' granites and alkali syenites All of these belong to the Basement Complex and are thought to be older than the Great Dyke and of Pre Cambrian age The mineral deposits are almost exclusively gold bearing quartz veins, of which about a hundred and sixty have been worked as small mines, producing gold valued at more than £2,750,000 up to the end of 1929 There was certainly one important period of ore formation during the later stages of consolidation of the 'younger granites, and there may also have been an earlier period Several excellent and detailed analyses of the igneous rocks are presented They disclose an important characteristic which deserves further attention namely, the abnormal richness in strontia in the rocks of three successive igneous cycles Baryta is rare in comparison, and thus the usual proportions of these oxides are reversed to an extent that is unknown elsewhere in the world

Fossil *Metacheiromys* -- G G Simpson, in the *Bulletin* of the American Museum, vol 59, 1931, has given a very full account of the genus *Metacheiromys* The precise position among the mammalia of these animals, which occur in Middle Eocene deposits of the United States, has hitherto been rather uncertain Their affinity to the Edentata has long been suggested, and Simpson now shows that this view is correct Although aberrant in some respects, such as the peculiar and reduced dentition, in others they are very primitive and represent an early side branch of the Xenarthra With regard to the origin of the edentates as a whole, Simpson considers that, with the exception of the Tubulidentates of South Africa, which are probably of proto ungulate stock, the American forms and the Asiatic Manidæ came from some branch of the Insectivora during the Cretaceous period

Active Earthquake-Faults in Tokyo — A comparison of the levellings made in the Tokyo area in 1918 and November 1923 reveals a zone of marked depression of as much as 24 8 in across the section of the city lying east of the river Sumida As no other great earthquake occurred in this interval within 25 miles of Tokyo, the change was probably due mainly to the earthquake of Sept 1, 1923 Since then, two new lines of levels have been carried across the area, in January 1926 and March 1930, the results of which have recently been examined by Prof A Imamura (*Tokyo Imp Acad Proc*, vol 7, pp 1 4, 1931) During each interval, a similar depression occurred in the zone mentioned, which forms a block between two north south faults about 4 miles apart The maximum depression during the first interval was 7 0 in and during the second, 22 0 in, the average secular depression of the district being less than 0 7 in a year During the first interval, no earthquake of any consequence occurred near Tokyo, but during the second, there was a semi destructive earthquake on May 21, 1928, with its epicentre near the sea and close to the eastern of the two faults mentioned Prof Imamura suggests that the earlier of the two depressions was a harbinger, and the later a consequence, of the movement that caused this earthquake As the earthquake that destroyed Yedo (Tokyo) in 1855 seems to have had its origin along the same fault, and as the two faults are not likely to remain inactive, he urges the desirability of keeping a close watch on the movements of the block

Distribution of Ice in the North Atlantic —The International Ice Observation and Ice Patrol Service in the North Atlantic has produced its report for 1930 (*Bulletin* 20, United States Coast Guard) Icebergs appeared off the Grand Banks of New foundland much earlier than usual The cutter *Tampa* began its service about seven weeks earlier than in 1929 owing to the presence of much ice A continuous patrol was maintained for 117 days, which was on the whole longer than usual, although the ice season ended so early as June 10 The conditions, however, were not so severe as in 1929, but the number of bergs was well above the average Only six bergs drifted south of the forty third parallel This is attributed partly to the narrowness of the southward flowing cold stream off the eastern edge of the Grand Banks These six bergs were closely watched by the patrol vessels, and three of them crossed important west bound shipping tracks The usual extension of cold water to the westward round the Tail of the Bank was also absent The report is illustrated by a number of charts showing the distribution of ice and surface temperature during the months of the patrol service

Magnetisation in Strong Fields —Prof P Kapitza's researches on the properties of bodies in very large magnetic fields, well beyond the range of ordinary electromagnets, are extended in new work described in the April number of the *Proceedings of the Royal Society* to the measurement of magnetisation The experimental arrangements are typical of many used by Prof Kapitza, being at once robust and very sensitive, and consist essentially of a magnetic balance with which the whole of the experiment is carried out in about one hundredth of a second, and the results recorded permanently in this time Typical ferromagnetic paramagnetic, and diamagnetic bodies have been studied With iron and nickel it has been shown that the state of saturation produced with relatively small fields persists, within the limit of experimental error (1 per cent) up to fields of 280 kilogauss, a result in accord with the Weiss theory With the para magnetic crystals of gadolinium sulphate—a substance studied exhaustively by Onnes at very low tempera tures— an indication of incipient paramagnetic saturation was obtained at liquid nitrogen temperatures Measurements have also been made upon monocrystalline bismuth This work, extensive and important as it already is, is nevertheless only preliminary, and very interesting results are to be anticipated when the necessary equipment and facilities for using liquid hydrogen and liquid helium as refrigerants have been developed

Pressure of Granular Material — A large collection of data bearing on the properties of granular material, a subject of much technical importance, is contained in a communication from Prof C F Jenkin in the April issue of the *Proceedings of the Royal Society* The work arose from attempts to measure the effective coefficient of friction of sand, some phenomena encountered being immediately recognised as examples of what Osborne Reynolds termed "dilatancy" This suggested certain lines of experiment on pressures on walls built in various ways, and subject to the influence of small bodies packed under different conditions, and the paper deals largely with results so obtained One result of immediate applicability is that the position of the centre of pressure on a wall is

determinate, it may be much higher than one third of the height of the wall, so that the distribution of pressure will often be different from the commonly accepted triangular distribution. The pattern of the packing of the grains is of fundamental importance, and as would thus be anticipated, ground and spherical preparations of a common material behave quite differently. Prof. Jenkin makes an interesting suggestion with regard to the variable nature of some results, which he assumes provisionally to be due to a variable adsorbed film of moisture on the grains.

Diffraction of Electrons in Polyatomic Vapours.—A recent paper by R. Wierl in the *Annalen der Physik* (vol. 8, p. 521) extends the use of electron waves to the study of the arrangement of atoms in polyatomic molecules. The principle of the method employed is that the nuclei of the atoms in each individual molecule are equivalent to a grating with a small number of diffracting elements, an analogous problem for X-rays having been solved by Debye. Electrons are, however, more rapidly absorbed than X-rays of the same range of wave-lengths which is useful for this purpose, so that the time of an experiment can be reduced to a fraction of a second. The apparatus consists essentially of a fine pencil of electrons from a discharge tube or thermionic source, which is made to traverse a beam of molecules passing through the same highly evacuated vessel, and to register its diffraction pattern photographically; the diffraction rings are photometered afterwards. By comparing the observed distribution of intensity with that predicted for various molecular models, considerable information has already been obtained about the structure of a number of organic and inorganic bodies.

Dimensional Changes in Heat-treated Aluminium Alloys.—As a result of a report that heat-treated aluminium alloys were liable to serious secular changes of dimensions during storage, Grogan and Clayton have investigated the point for several such materials and found no appreciable change to occur, the variations which were observed being so small as to be negligible for all practical purposes. Their investigations were described in a paper read on Mar. 12 at the annual general meeting of the Institute of Metals. When the heat-treated alloy is machined, however, considerable changes in the dimensions may be found. These are greatest in the case of *Y* alloy and least in a copper-silicon alloy. Since the annealed bars do not give these effects, it is clear that it is to internal strains due to the heat treatment that the variations are to be ascribed. In *Y* alloy and duralumin, the only alloys examined in this direction, quenching in cold oil reduces the dimensional changes which occur on machining as compared with those resulting from quenching the material in cold water. If the alloys are quenched in boiling water, which is shown to bring about quite satisfactory hardening, the distortion is reduced to relatively small proportions. Tempering subsequent to the hardening reduces the changes in '25 S' alloy, but increases them to a slight extent in the copper-silicon material.

Effect of Firedamp on Inflammation of Coal Dust.—For some time, the mining engineer has distributed stone dust underground as a means of stopping the propagation of coal dust explosions in mines, and rules have been drawn up for regulating the proportion of incombustible material in the mine dust necessary to ensure safety. It is an important question whether the presence of firedamp in the air underground would make the extinction of an explosion more difficult. In a recent paper, No. 64 (H.M. Stationery Office, 6d. net), issued by the Safety in Mines Research Board, experiments on "The Effect of the Presence of Firedamp on the Inflammation of Coal Dusts" are recorded. They showed that the presence of inflammable gas necessitated the use of an increased quantity of stone dust, the proportion depending on the nature of the coal. A coal dust the danger of which is neutralised by an equal quantity of stone dust, when no firedamp is present, would require about 5 per cent more stone dust for each 1 per cent of firedamp in the air.

Fuel Testing in Slow and High Speed Diesel Engines.—Data relating to oil fuel for internal combustion engines have a special interest for the engineer in view of the modern development of the heavy oil high compression engine in small power units both for stationary work and for traction. In a paper read before the Institution of Petroleum Technologists on Mar. 10, L. J. Le Mesurier and R. Stansfield attempted a survey of the behaviour of fourteen different types of fuel when used in slow and high speed engines of low power running under approximately standard conditions. The engines experimented with differ in three main particulars, namely, speed of running, design of combustion space, and arrangement of injection gear for the fuel, although all employ the solid injection system. The programme of work is very wide and includes the effect of leakage of fuel upon the running of the engine, fuel consumption, and the process of combustion. The authors also experimented with various dopes and have indicated the effects of these upon the fuels used. Many graphs and diagrams are published with the paper, among the most interesting being those dealing with the 'delay angle' for each fuel, and also those diagrams indicating the 'combustion line' for each fuel which are obtained from the different engines. The results presented by the authors should be of value to all those interested in the design and performance of the small powered oil engine, and should be suggestive of further work in this direction.

An Improved Metallographic Microscope.—Many improvements tending to secure a high degree of rigidity and ease of manipulation have been embodied in the redesigned Leitz metallographic microscope. The improved optical system gives a very flat field and is provided with a new type of illuminator giving conical illumination, that is, oblique in all azimuths, thus permitting wide angles to be used without the introduction of glare. Another illuminator, consisting of a glass plate and a small lens, can easily be inserted when photographic objectives of short focal length are being used. The mechanical design is such as to minimise so far as possible the necessary movements of the operator in manipulating the apparatus. The transition from visual observation to photographic work is made by rotating the viewing eyepiece. The observer can view the image to be photographed through an opening in the side of the camera without changing his position by the ocular. In addition, a mirror fitted to the camera stand can be used for purposes of demonstration or observation of the image on the ground glass screen. The arc lamp, which has a steady crater, is interchangeable with a filament lamp for use when a less intense source of light is desired. A noteworthy feature of the outfit is the vibration absorbing device on which the prismatic optical bench carrying the saddle stands is suspended. By its use the difficulty of obtaining photomicrographs in rooms subjected to vibration is obviated. Full particulars of the apparatus and accessories may be obtained on application to Messrs. E. Leitz, 20 Mortimer Street, London, W.1.

Optical Experiments with Electrons.*

It is now seven years since L. de Broglie brought forward the view of the duality between waves and particles which is now almost universally accepted under the name of wave mechanics, and represents one of the greatest advances in physics of this or any other century. The original treatment was a development of the theory of relativity, but this side of his theory can no longer be kept in its original form. It appears, in fact, that the requirements of relativity are closely connected with the magnetic properties of the electron which gave rise on the older theory to the idea of a 'spinning electron' and were not considered by de Broglie. I do not propose to deal with these, and shall give the theory in the approximate form which is sufficient to explain the experiments I propose to describe.

The basis of the whole is a duality between waves and particles which is common both to matter and radiation. Maxwell made optics a branch of electricity; if de Broglie has not reversed the relation, he has at least shown both as different cases of a common principle, which is more like old fashioned optics than old fashioned electricity. The duality takes this form: any observable atomic event is representable as the arrival or departure of a particle at or from a small region of space, but the laws which govern this event involve a quantity which is best thought of as the amplitude of a wave (possibly in multidimensional space). In the case of light, this quantity is indeed the electric or magnetic vector of the Maxwell wave (it is indifferent which).

In the case of electrons, it is the more elusive ψ which obeys also an equation of the type known to mathematicians as a wave equation. In general, ψ is complex, for the equation is complex, so no direct physical meaning can be assigned to it. Its modulus $|\psi|$ is real, and de Broglie gives as his 'principle of interference' the statement that the chance of the presence of an electron at a given place and time is proportional to $|\psi|^2$. The analogous statement in optics is that the chance of a quantum of light appearing at a given place and time is proportional to the square of the amplitude of the Maxwell wave.

According to de Broglie's theory, the wave length associated with a free electron is $\lambda = h/mv$ where h is Planck's constant and mv the momentum. He enunciates, therefore, a 'law of spectral distribution', according to which the chance of the presence of an electron with a given momentum is proportional to the square of the modulus of the Fourier component of the wave the wave length of which corresponds to the given momentum. In optics, the chance of the appearance of a quantum of energy W is proportional to the square of the Fourier component of the Maxwell wave of wave length hc/W.

This simple correspondence between electron and quantum—ψ wave and Maxwell wave—in the case of the free electron prepares us for a close experimental analogy. In fact, we can repeat many optical experiments with electrons and get strikingly similar results. The chief differences are due to the smaller wave length, which is usually less than that of X rays, and the much smaller penetrating power. Davisson and Germer made experiments with electrons which are analogous to the diffraction of X rays by a single crystal, as in the Bragg method.

Other experiments have reproduced with cathode rays the diffraction of X rays by a crystalline powder, and have verified de Broglie's law of wave length with considerable accuracy. Some recent work with cathode rays and single crystals of copper and silver provides the electron analogy to the optical experiment in which two transmission diffraction gratings

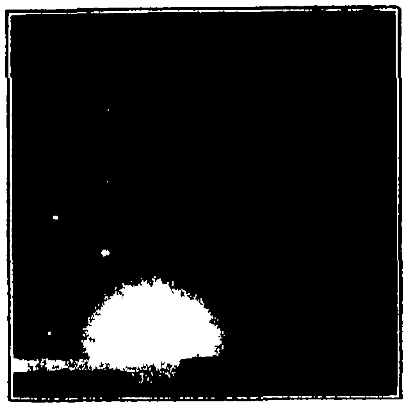

FIG. 1.—Diffraction pattern of cathode rays incident on a cube face of a single crystal of silver.

are superposed with their rulings inclined to each other (Fig. 1). The etched surface of the single crystal is apparently covered with a number of small lumps, probably the material left between etching pits. The cathode rays strike the crystal at a small glancing angle to the main surface, and pass through the lumps, being diffracted by the atoms in them. If the thickness of the lump in the direction in which the rays traverse it, is less than a certain amount, which for the angles of diffraction and electronic wave lengths used is of the order 10^{-6} cm., the thickness has no influence on the pattern. The diffracting system is then equivalent to an arrangement of atoms in the plane normal to the rays, and this two dimensional array is mathematically equivalent to the crossed gratings of the optical experiment, giving rise to an array of spectra which is reciprocally connected with the atomic array producing it.

The spectra, when received on a fluorescent screen, are bright enough to be shown to a small audience.

* From a lecture delivered by Prof. G. P. Thomson, F.R.S., before the Optical Society on May 14.

Indian Fossil Plants

IN 1928, Prof. Sahni produced the first part of an important work on Indian fossil plants. It dealt with the fossil coniferous plant remains found in the form of impressions and incrustations in rocks of the Gondwana System in India. The majority of the fossils described were of Mesozoic age, but there were also a few Palæozoic species of a doubtful nature.

In the second part of the work, which has recently been published,* Prof. Sahni extends his researches to petrified coniferous plants, providing descriptions of much that is new and interesting, as well as revising earlier work on this subject. The material with which

* Memoirs of the Geological Survey of India. *Palæontologia Indica*, New Series, vol. 11. Revision of Indian Fossil Plants. Part 2, Coniferales (b. Petrifactions), by Dr. B. Sahni. Pp. 47-124 + plates 7-15. (Calcutta: Government of India Central Publication Branch, 1931.) 7.0 rupees; 12s.

he deals has been accumulating for many years in the collections of the Geological Survey of India, and some of the specimens are preserved in the British Museum As Prof Sahni remarks, it is unfortunate that the localities and horizons of so many of the specimens are not known with certainty In spite of this serious disadvantage, Prof Sahni adds very considerably to our knowledge of the Coniferales

Most of the petrifactions are of secondary wood and belong to either the Jurassic or Cretaceous age They include the following form genera *Mesembrioxylon*, *Cupressinoxylon*, and *Dadoxylon* (*Araucarioxylon*) It is curious that there is no mention of *Dadoxylon indicum* or *Dadoxylon bengalense* Holden, two palæozoic fossil woods which are certainly gymnospermous, while the latter is as likely to be coniferous, in view of its structure, as any of the Mesozoic species of *Dadoxylon* described by Prof Sahni These two Indian fossil woods are particularly interesting, since they resemble, in certain important characters, species described from the Karroo formation in South Africa Prof Sahni cites this work by Holden in part 1, but does not mention either of these two species

A new genus of cone, *Indostrobus*, is described It bears bract and ovuliferous scales as in the living pine, but differs in the ovuliferous scale being forked at its distal end The seeds are placed on the ovuliferous scale at some distance from the cone axis Prof Sahni recognises features reminiscent of the podocarps in the structure of this cone, but at the same time is clear that it is most closely related to the Pinaceæ He also produces clear evidence of the existence of araucarian conifers in the Jurassic of the Gondwana system The podocarps, if one may judge not only from the various types of fruits and foliage but also from the numerous examples of secondary wood, were abundant and had a wide geographical distribution in India in the Jurassic and Cretaceous

The contrast between the present and past distribution of conifers in India is stressed by Prof Sahni There is only one native conifer in peninsular India at the present day There is no native living conifer in Ceylon The living conifers are restricted, in greater India, to the Himalayas with their connected ranges and to Assam and Burma In the Tertiary Period there is apparently an almost complete absence of conifers in the India floras so far investigated, and the Indian Tertiary floras would appear to have been almost exclusively angiospermous There is only one record of Indian Tertiary coniferous wood and that is from Southern India In the Cretaceous Period the traces of conifers are fairly numerous, but the group appears to have enjoyed its maximum development in the Jurassic It is a remarkable fact that no fossil conifers are recorded from extra peninsular India

On the strength of these facts, Prof Sahni concludes that the conifers were confined in Mesozoic times to peninsular India Later they gradually approached extinction, and when the Himalayas were brought into existence in the Tertiary Period the conditions for coniferous growth were reintroduced and an invasion of the modern coniferous flora took place from the landward borders

From a consideration of their respective floras, Prof Sahni considers that the Parsora Stage of Dr Cotter s 1917 classification of the Indian Gondwana System is of Triassic age, and that the Maleri Stage must be referred to the Upper Gondwanas and not, as has been done previously, to the Lower, for the flora suggests an age at least as late as the Rhætic He considers that while it is clear that Ceylon and the Madras region formed part of the same palæobotanical province in Upper Gondwana times, it is possible that the flora of the Mesozoic plant beds of the Southern Shan States had a closer connexion with the contemporaneous floras in China than with the Indian Upper Gondwana floras

Valuable synoptic charts and distribution maps are given One of the many outstanding good qualities of these memoirs is the excellence of the illustrations and by means of these the evidence is put before the reader in a manner which leaves little to be desired All palæobotanists and those geologists who are interested in the stratigraphy of the Indian Gondwana System will look forward to the extension of Prof Sahni's researches to the other groups of Indian fossil plants

Physics in Relation to the Internal Combustion Engine *

THE development of all internal combustion engines using gas or oil as a fuel and for all duties, whether stationary on land or for transport, road, marine, or in the air, owes more to the guidance of physics than any other prime mover

In the first period, when the engine was nearly always a gas engine, the investigation of the processes which governed its action and the limitation of its cycle of working were carried out by physicists like Sir Dugald Clerk, Prof Hopkinson, and others The results assisted and accelerated development making possible the extended use of the engine for all industrial purposes that followed

Perhaps the outstanding feature during this time was the growth of the engine in size, until ultimately engines using the waste gases from blast furnaces were built, or are building, for powers so large as 10,000 h p per engine These large size engines are found usually abroad, operating in the most efficient iron and steel works As regards the smaller sizes in Great Britain, they would have been used more widely if the gas industry had foreseen the possibilities of a country wide gas supply with interconnecting trunk mains, as has been done since by the electrical industry

The War period followed, and led to an intensive and rapid development in the engine for transport, in particular in the air, where special materials and increased accuracy of workmanship were called for The extraordinary progress made was largely due to the number of highly trained physicists and engineers who concentrated upon every problem and solved it as it arose

Since the War, development has been in the use of oil, and the wide adoption of the engine for marine propulsion has been due to the high economy of the Diesel motor The high economic possibilities of this engine were thoroughly discussed in a paper by Diesel before the engine was actually built, and though it took many years to bring this into practice the results have justified all that he had proposed At the present time, development is being concentrated upon the high speed oil motor using relatively cheap fuel, with the added advantage of reducing the risk of fire, for road transport and for the air, and very good progress is being made

The first 'safety first' engines to fly regularly were those supplied to the airship *R101* Since then one has flown in the United States and one in Germany, and these will shortly be followed by another type in Great Britain

On the road, extraordinary progress has taken place in the application of the small engine to motor lorries,

* From a lecture delivered by Alan E L Chorlton before the Institute of Physics on May 19

etc , the economy with cheaper fuel and using less of it has been so marked This class of engine has called for the most intensive investigation and research that has ever been carried out in the internal combustion engine world Much valuable laboratory work has been carried out in the United States by the National Advisory Committee for Aeronautics in connexion with their air work, and elsewhere

This reveals the intensity of effort which will before long ensure that not only will the oil engine become predominant for road work of heavier nature, but also for the air, where its great safety from the fire risk, coupled with its economy, makes it so highly suitable The use of coal dust in the engine progresses very slowly for a country like England, the industrial supremacy of which is founded on coal This is to be regretted, and we should conduct special work with this object

In all the development of the engine, the steady improvement of the material has been the measure of the progress made To day we have new steels practically unwearable—allowing high speeds and long life, and also of such strength that motors like the Schneider Cup engine weigh less than 1 lb per h p —and a degree of excellence of workmanship not ex celled, if equalled in all the world

University and Educational Intelligence

Birmingham At the annual degree congregation on July 4, the honorary degree of M Sc is to be conferred on the following R A Chattock, formerly chief electrical engineer to the City of Birmingham, W Wickham King, known for his work on the Permian breccia, J H Reynolds, who has made a special study of the nebulæ, and J J Shaw, known for his seismo logical work

Prof J C Brash is resigning his posts as professor of anatomy and dean of the Faculty of Medicine on being appointed to the chair of anatomy in the University of Edinburgh

Cambridge —A meeting of the electors to the Sadleirian professorship of pure mathematics will be held on June 12 The stipend of the professor is £1200 a year or, if he holds a fellowship with dividend, £1000 a year Candidates are requested to communi cate with the Vice Chancellor on or before June 2

A University lectureship in the faculty of mathe matics is vacant An appointment to it will be made in the current term, to take effect from Oct 1 Candidates are requested to send their names, with any evidence of qualifications which they may desire to submit, to Mr W J Harrison, Secretary of the Faculty Board of Mathematics, Clare College, Cam bridge, on or before May 30

The General Board recommends that an additional University demonstratorship be established in the Department of Zoology

Prof G Elliot Smith, professor of anatomy in University College, London, has been elected an honorary fellow of St John's College

London —At a meeting of the Court of the Univer sity held on May 13, the Principal, Dr Edwin Deller, read his annual report of the work of the University for the year 1930–31 The statistics for that year have brought out some striking facts concerning the number of students For example, the number of matriculations has almost quadrupled since just before the War A great increase has taken place in all branches of study For the year 1913, the numbers of matriculations, first degrees, and higher degrees were 6638, 1636, and 171 respectively The corresponding numbers for 1929 were 23,832, 3436, and 510, and for 1930, 25,544, 3543, and 548 The total number of degrees, diplomas, and certificates awarded for those three years were 11,937, 36,633, and 39,323 During the last decade, the inspection and examination of secondary schools have received much attention, and the growth of the school examinations has been specially noteworthy

The Goldsmiths' Company has offered the Univer sity a sum not exceeding £50,000 towards the cost of erecting and equipping the library building on the Bloomsbury site The University library, at present housed in the Imperial Institute, South Kensington, contains a total of some 260,000 volumes and pamph lets, and includes, with other special collections, the Goldsmiths' Library of Economic Literature

Applications for grants from the Research Fund of the Chemical Society must reach the Assistant Secretary of the Society, Burlington House, W 1, by June 1, and be made upon special forms obtain able upon application

Applications are invited by the London County Council for two Robert Blair fellowships in applied science and technology, each of the value of £450 and for one year The fellowships will be tenable in the Dominions, the U S A or other foreign countries, and are open only to British subjects of not less than twenty one years of age Particulars and application forms can be had from the Education Officer (T 3), The County Hall, S E 1 The latest date for the return of forms of application is June 18

A number of post graduate scholarships in agri culture and agricultural science and in veterinary science respectively will shortly be awarded by the Colonial Office The scholarships, which will each be of the annual value of £250, plus £12 for books, have been instituted with the view of ensuring a supply of adequately trained men for future service in the Colonial Agricultural and Veterinary Services Re quests for particulars of the scholarships and for the necessary forms of application should be addressed to the Director of Recruitment (Colonial Service), Colonial Office, 2 Richmond Terrace, Whitehall, S W 1 The latest date for the return of completed forms is June 15

The twenty second annual Conference of the Association of Teachers in Technical Institutions will be held at Manchester on May 22 26, under the presidency of Mr H Ade Clark The Conference will be held at the College of Technology In connexion with the Conference an exhibition of machines, scien tific apparatus, and books will be opened on May 25 Among the resolutions for public sessions is the motion that a representative of technical education should be appointed to the Consultative Committee of the Board of Education The teaching of biology, too, will receive consideration A considerable amount of biology is taught in many technical schools and colleges, but this is chiefly of a purely technical char acter for the benefit of pharmaceutical chemists The resolution to be placed before the Conference, how ever, will be of a wider nature It is considered that a knowledge of biology is an essential part of a sound general education, and that more experts in the subject are required for the advancement of agriculture and industry The Conference is to ask for the teaching of elementary biology in all State aided schools and an increase in the facilities for higher education in bio logical subjects The latter is scarcely necessary The facilities are there, but the former really needs attention A better groundwork in the younger pupils is certainly desirable Much has already been sug gested concerning it; but little, so far, has been done.

Birthdays and Research Centres

May 24, 1855.—Dr. A. C. HADDON, F.R.S., formerly reader in ethnology in the University of Cambridge.

At present I am engaged in compiling published and unpublished information concerning the sea canoes of Melanesia, New Guinea, and North Queensland. The original craft are, in many areas, fast disappearing or becoming modified, and in some places have quite disappeared. Not only do these canoes often exhibit remarkable technical skill and adaptability to local circumstances, but also considerable diversity. The distribution of the various types and details of construction of these vessels is worth recording, since these were the means by which the various migrations and culture drifts have spread over western Oceania. The names for canoes and their various parts are significant in this connexion. Very little has been recorded about the traditional relation between definite types of canoes and culture-heroes or culture drifts. It is hoped that a foundation will be provided upon which other ethnologists may build.

May 24, 1860.—Prof. A. SMITHELLS, F.R.S., director of the Salters' Institute of Industrial Chemistry and emeritus professor of chemistry in the University of Leeds.

So far as research work is concerned, I continue with the study of some flame problems and, with a long-standing connexion in the gas industry, with scientific investigations relating to the carbonisation of coal and the use of gaseous fuel. The advances that are being made by this branch of our fuel industries in the application of science to its technical problems, and the results which have accrued from industrial research conducted by the gas industry and the benzol industry in association with the University of Leeds, are, I think, notable. The national importance of directing research to fuel problems on every side scarcely needs emphasising in the columns of NATURE.

May 25, 1858.—Sir HENRY MIERS, F.R.S., honorary professor of crystallography and lately vice-chancellor of the University of Manchester.

The splendid results of X-ray methods will not, I hope, distract attention from two promising lines of research in mineralogy and crystallography. (1) Experimental mineralogy: that is, the artificial production of minerals, both rock-forming and others, and the study of their origin and transformations. The lack of a geophysical laboratory in Great Britain has long been deplored. (2) Crystal growth: that is, the study of the conditions which prevail in and upon the surface of the growing crystal; these determine its actual form; perhaps also its external symmetry, as some believe.

May 25, 1865.—Prof. P. ZEEMAN, For.Mem.R.S., professor of experimental physics in the University of Amsterdam.

My co-workers and I are at present most interested in the experimental study of the influence of magnetic fields on the hyperfine structure of spectrum lines. Values of the mechanical moment of the atomic nucleus obtained from such magneto-optical resolutions are among the most important data for the further development of the quantum theory. A second line of work, concerning the more detailed analysis of the light given out by positive rays, which, as Stark and Lunelund have shown, is partially polarised, is in the charge of Miss W. Lub. An extensive study, made in my laboratory, of the magnetic resolutions of the spectra of the ionised noble gases, will soon be published by Mr. Bakker.

Constant progress is being made in the analysis of different spectra, especially by Dr. de Bruin.

May 28, 1861.—Dr. H. R. MILL, vice-president and formerly librarian of Royal Geographical Society and president of Section E (Geography) of the British Association in 1901, past president of Royal Meteorological Society and Director of British Rainfall Organization.

I worked long at researches preliminary to the construction of an accurate map of the normal annual rainfall of the British Isles, and I hope that the work will be continued and completed by better equipped and more fortunate investigators.

The practical problem present to my mind is to draw isohyets of the average annual precipitation from air currents impinging horizontally on land slopes. Such a map would express exactly the control of a mobile distribution by crustal configuration undisturbed by the sporadic precipitation produced by ascending air currents of purely aerological origin occurring in cyclones, squalls, and thunderstorms. Centuries of observations would be required to produce a map of total rainfall in which such sporadic splashes would be smoothed out; but I believe that a method of eliminating these irregularities in shorter periods might be deduced from the study of very detailed maps of individual showers together with equally detailed synchronous maps of atmospheric pressure.

May 29, 1882.—Prof. H. BATEMAN, F.R.S., professor of mathematics, physics, and aeronautics in the California Institute of Technology, Pasadena, California.

My chief investigation now in progress is on reflection at an absorbing wall of the sound from a point source.

Societies and Academies.

LONDON

Royal Society, May 7.—**M. D. Waller:** (1) The measurement of actinic erythema produced by ultra-violet radiation with special reference to the latent time. Consistent results regarding the biological action of ultra-violet radiation, as measured by the resulting skin erythema, can be obtained provided certain precautions are taken. The latent time of erythema, which may vary from about one to seven hours, according to the length of exposure, provides the most accurate and simple way of estimating the effect of ultra-violet radiation on the skin, and it is easily measured. When it is desired to get the maximum contrasts due to differing conditions of radiation, exposures should be chosen which will lie on the steep part of the curve, corresponding to rapid variations of the latent time with exposure and to slight erythemas which will differ even visually one from another more than will deep erythemas.—(2) The relation between energy doses of ultra-violet radiation and actinic erythema produced. Particular attention was paid to the question of how the intensity of the radiation decreases with the distance from the source. The intensities were varied over wide limits (200 : 1) corresponding to distances varying from 40 cm. to 5.5 m. The effect of a given dose of the weak intensity is just as great as that of the most powerful intensity used, and it is concluded that the production of erythema follows the Bunsen-Roscoe law for a

photo chemical action, that is, the time factor is unity —**J W Tudor Thomas** On the return of sensitiveness in corneal grafts in rabbits In a series of experiments on corneal grafting, some of the grafts became sensitive and others did not The results of 29 experiments are analysed Some of the grafts were central in position in the cornea, others marginal Some remained or became clear, others became more or less opaque, while one exhibited a central clear area The establishment of an afferent nerve supply to a corneal graft depends upon a precedent or concurrent growth of blood vessels in that graft It does not seem to be necessary that the blood vessels should accompany or take the same path as the afferent nerves that grow in from the surrounding tissue —**G E Briggs** and **A H K Petrie** Respiration as a factor in the ionic equilibria between plant tissues and external solutions The conductivity of water containing slices of tissue from carrot root rises at first and then falls to a steady value, which is maintained as long as the tissue is alive The rate of evolution of carbon dioxide by the system follows a similar course to that of the conductivity Theoretical consideration shows that variations in the rate of production of carbon dioxide by the tissue will be accompanied by similar changes in the concentration of hydrogen ions in the tissue This will result in changes in the degree of ionisation of indiffusible substances, such as proteins with consequent changes in the distribution of diffusible ions, such as K and Cl between the tissue and the external solution The final result of this chain of events will be a parallelism between rate of production of carbon dioxide and conductivity of external solution **McKeen Cattell, T P Feng, W Hartree, A V Hill,** and **J L Parkinson** Recovery heat in muscular contraction without lactic acid formation Muscles poisoned with iodo acetic acid contract without producing lactic acid Functional recovery in oxygen after stimulation can be demonstrated under certain conditions *in such muscles* The *persistence* of this 'recovery' heat suggests that one effect of iodo acetic acid is to interfere with the mechanism by which energy released in oxidation can be employed in driving the endothermic reactions necessary for functional recovery, it does not interfere with oxidation as such Normal muscles stimulated to extreme exhaustion have a 'recovery' heat only about one quarter of its usual value in relation to the initial heat Possibly in normal muscles pushed to extreme exhaustion as in muscles poisoned with iodo acetic acid one reason of incomplete recovery is that phosphate set free by the breakdown of creatine-phosphoric acid is 'side tracked' as hexose phosphoric ester and so cannot be recombined with creatine **A G R Whitehouse** Further investigation of sweating and sweat For a given rise in body temperature, sweating is facilitated by the performance of muscular work when compared with sweating produced by the same rise in body temperature with the subject at rest Some product of muscular metabolism is responsible for this, though the connexion may be a less direct one The performance of a moderate amount of work would seem to be accompanied by little rise in the chlorine concentration of the sweat, although a marked increase with time, indicative of fatigue of the sweat glands, is evident when the subject is at rest and the sweating is simply due to the wet bulb temperature of the surrounding air A progressive decrease in the proportion of organic matter to ash is observed as the sweating continues The chlorine concentration, and also the ratio of chlorine to potassium in the sweat is found to vary for different individuals —**R Snow** Experiments on growth and inhibition (2) In decapitated pea seedlings, which have produced two equal shoots springing from the axils of the cotyledons, if one of the shoots is deprived of its leaves until only those of 1 mm or less remain, it is rapidly arrested in growth and finally killed This effect must be due to inhibition coming from the other shoot The influence coming from developing leaves kills (directly or indirectly) those shoots or parts of shoots that are not in the line between developing leaves and roots and in which it travels towards the apex, and this fact also suggests that it is of a polar nature

Geological Society, April 22 —**H H Thomas** and **W Campbell Smith** Xenoliths of igneous origin in the Trégastel Ploumanac'h granite, Côtes du Nord France In the neighbourhood of Trégastel, a red porphyritic biotite granite crops out along the coast and forms the rising ground for several miles inland In parts, this granite is remarkable for the abundance of xenoliths which it contains Some of these are of sedimentary origin, but the majority are of the kind usually referred to as 'basic segregations' The occasional presence of large felspars in the xenoliths is discussed, and the authors are of opinion that these are xenocrysts and have not grown in place Evidence is produced to show that the basic mass from which the xenoliths were derived was most probably part of the roof of the granite —**C I Gardiner** and **S H Reynolds** The Loch Doon 'granite' area, Galloway The plutonic rocks are almost everywhere surrounded by high hills composed of metamorphosed Ordovician sediments Analyses were prepared by Mr E G Radley of each of the three rock types The most interesting problem concerning the plutonic mass is *to determine the mutual relations of the rocks* and to ascertain whether their different varieties may be considered to have arisen by differentiation subsequent to intrusion, or whether the facts point to each of the three rock types being a separate intrusion The authors believe the latter to be the true explanation No evidence was found of contamination of the igneous magma by the incorporation of sedimentary material

PARIS

Academy of Sciences, April 7 —**Charles Camichel** and **Léopold Escande** An experiment of Joule concerning the mechanical equivalent of heat —**A Gelfond** The order of $D(\lambda)$ — **G A Boutry** Cycles and lag in photoelectric cells with a gaseous atmosphere —**J Barbaudy** and **A Petit** Study of the buffer effect in nickel plating baths —**E Herzog** and **G Chaudron** The protection of iron plunged into aerated saline solutions and the realisation of an Evans battery —**L Meunier** and **M Lesbre** The action of electrolytes upon substantive colouring matters —**H Forestier** The ferrites the relation between their crystalline structures and their magnetic properties The magnetic properties of the ferrites have been shown previously to fall into different groups The X-ray study of the crystalline structure of these compounds proves a direct relation between the crystalline structure and the magnetic properties —**Maurice Marie Janot** Sclareol and its derivatives The formula $C_{17}H_{30}O_2$, provisionally given to the solid alcohol obtained from *Salvia sclarea*, is now found to be $C_{20}H_{36}O_2$ This results from a purer product and is confirmed by the preparation and analysis of a dihydrosclareol —**Louis Lecoq** The complex salts of gold and sodium derived from camphodithiocarboxylic acid —**Acolat** Physiological researches relating to the separation of the venous blood and arterial blood in the frog's heart The peculiarities of the structure of the frog's heart described in an earlier paper

(*C R*, 192, p 767) suggested that the separation of the two bloods in the ventricle is nearly complete Confirmatory evidence is now given, based on the use of a coloured Ringer-Locke physiological liquid —**R Fabre** and **H Simonnet** Researches on beer yeast The experimental conditions of its action on cystine —**A Boutroux** The influence of lipoids on the separation of the proteins by neutral salts —**Paul Durand** *Rhipicephalus sanguineus* and the virus of the pustular fever of Tunis In Tunis, as in the Midi (France), apart from any connexion with human cases, *Rhipicephalus sanguineus* can harbour the virus of pustular fever and keep it intact for several weeks —**P Delanoë** The merion (*Meriones Shawi*) as a reservoir of the Moroccan spirochæte *Sp hispanicum*, var *marocanum* Out of twenty one merions, two were found to be infected, or about 10 per cent, but the exact proportion of infected merions can only be settled by further work It is, however, certain that this rodent can be spontaneously infected by the Moroccan spirochæte

GENEVA

Society of Physical and Natural History, Dec 20 —**L A Deshusses** and **J Deshusses** Estimation of the active principles of pyrethrum The authors have studied pyrethrums of Swiss, French, Spanish, and Dalmatian origin, estimating the two active pyrethrins which give a direct measure of the efficiency of pyrethrum insecticides All these products contain about the same proportions of the active principles, the maximum having been furnished by French pyrethrum cultivated at Bossey (Haute Savoie) and at Montpellier For each of these products, the fully opened flower always gives a much higher percentage than the half opened flower, and the latter more than the closed flower —**E Cherbuliez, F Neumeier,** and **H Lozeron** Some synthetic substituted ephedrins The authors give results of a pharmacological study of some synthetic derivatives of ephedrin, showing how the specific action of this alkaloid is profoundly modified by slight changes of constitution **E Cherbuliez** and **M Schneider** The non homogeneity of casein Casein, hitherto considered as a homogeneous substance, has been separated by physical methods into at least two constituents This necessitates a modification of the current views on the physiological formation of this important substance and on the phenomena of its precipitation by rennet —**E Cherbuliez** The behaviour of two antipodes in an unsymmetrical solvent The author has examined the behaviour of two antipodes in a solvent constituted for the two antipodes dissolved by the same active substance A difference between the properties of the two antipodes is not shown by the solubilities, but, on the other hand, racemisation in presence of the active solvent appears to lead to an active body, and this proves a difference in the reaction of the two antipodes in solution, in spite of the absence of chemical combinations in the ordinary sense of the word —**R Wavre** A measure of the deformation of a fluid By an analysis based on the functional calculus, the author expresses more exactly the ideas of the deformation of a fluid, in order to obtain more rigid definitions of the stability of the states of a system depending on an infinity of parameters The object of this is to study the changes of form that the earth may have undergone in the course of ages, influenced as it is by the solar lunar attraction —**W H Schopfer** An active substance found with maltose Its physiological action The author shows that along with maltose there occurs a nitrogenous impurity, probably a vitamin it accelerates the development of fungi

Diary of Societies.

FRIDAY, MAY 22

INSTITUTION OF ELECTRICAL ENGINEERS (London Students Section) (Annual General Meeting), at 6 15.—Exhibition of a Cinematograph Film The Story of Bakelite Resinoid

SOCIETY OF CHEMICAL INDUSTRY (Newcastle Section) (at Armstrong College, Newcastle-upon-Tyne), at 7 30.—Dr J T Dunn Chairman s Address.

ROYAL INSTITUTION OF GREAT BRITAIN, at 9 —Sir William Bragg X Ray Investigations of the Structure of Liquids.

TUESDAY, MAY 26

ROYAL SOCIETY OF MEDICINE (Medicine Section), at 5 —Annual General Meeting

QUEKETT MICROSCOPICAL CLUB (at 11 Chandos Street, W 1), at 7 30 —Gossip Meeting.

WEDNESDAY, MAY 27

BRITISH ASTRONOMICAL ASSOCIATION (at Sion College), at 5

ROYAL SOCIETY OF MEDICINE (Comparative Medicine Section), at 5 —Annual General Meeting

SOCIETY OF SWEDISH ENGINEERS IN GREAT BRITAIN (at Swedish Chamber of Commerce, 14 Trinity Square, E C 3) at 8 —A F Enstrom Research in Industry and Rationalisation

BRITISH PSYCHOLOGICAL SOCIETY (Medical Section) (at Medical Society of London), at 8 30 —Dr R. Money Kyrle The Remote Consequences of Psycho Analysis on Individual, Social and Instinctive Behaviour

THURSDAY, MAY 28

ROYAL SOCIETY OF MEDICINE (Urology Section) (Annual General Meeting), at 8 30 —A R Thompson Further Considerations Relative to Congenital Deformities of the Lower Urinary Tract

FRIDAY, MAY 29

ROYAL SOCIETY OF MEDICINE (Disease in Children Section), at 5 —Annual General Meeting

ROYAL SOCIETY OF MEDICINE (Epidemiology and State Medicine Section) (Annual General Meeting), at 8 —Sir William Hamer The Crux of Epidemiology

ROYAL INSTITUTION OF GREAT BRITAIN at 9 —Very Rev Dean Inge The Future of the Human Race

SATURDAY, MAY 30

ROYAL SOCIETY OF MEDICINE (Therapeutics and Pharmacology Section) (Annual General Meeting) (at Cambridge)

PUBLIC LECTURES.

FRIDAY, MAY 22

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE (Public Health Division), at 5 —Prof E L Collis Industrial Hygiene Respiratory Diseases.

BIRKBECK COLLEGE at 5 30 —Sir Henry Hadow The Philosophy of Lord Haldane (Haldane Memorial Lecture)

TUESDAY, MAY 26

INSTITUTE OF PATHOLOGY AND RESEARCH (St Mary s Hospital, W 2), at 5 —Col S P James The New Method of Studying Malaria and Some of its Results

WEDNESDAY, MAY 27

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE (Public Health Division), at 5 —Dr R. H Crowley Child Guidance

BEDFORD COLLEGE FOR WOMEN, at 5 15 —Prof A O Lovejoy Knowing and its Place in Nature (Succeeding Lectures on May 28 and 29)

KING S COLLEGE, LONDON at 5 30 —Dr W Rosenhain Some Impurities in Metals and the Production of Metals of High Purity (Armourers and Brasiers Company Lectures). (Succeeding Lectures on June 3 and 10)

THURSDAY, MAY 28

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE (Public Health Division), at 5 —Dr F C Shrubsall Mental Deficiency from the Social, Legal, and Educational Aspects

FRIDAY, MAY 29

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE (Public Health Division), at 5 —N Howard Mummery An Industrial Welfare Scheme

SATURDAY, MAY 30

UNIVERSITY COLLEGE, LONDON, at 2 30.—Sir Flinders Petrie The City of the Shepherd Kings (*To be repeated on June 2 at 5 30.*)

CONFERENCES.

MAY 22 TO 26

ASSOCIATION OF TEACHERS IN TECHNICAL INSTITUTIONS (at Manchester).

Monday, May 25 (at College of Technology), at 10 30 A M.—Induction of President (H Ade Clark).—Presidential Address.

MAY 25 TO 28

DEUTSCHE BUNSEN GESELLSCHAFT (at Vienna).—Subjects for discussion Metallography, Crystal Structure, Thermodynamics, Spectroscopy, Adsorption, and Free Radicals

MAY 27 TO 29

CONFERENCE ON MENTAL HEALTH (at Central Hall, Westminster)

Wednesday, May 27, at 8 15 —The Human Factor in International Problems.

Thursday, May 28, at 3 —The Human Factor in Crime.
At 8.15 —The Human Factor in Industry

Friday, May 29, at 3 —The Human Factor in the Social Services.
At 8.15.—The Human Factor in Education

MAY 28 TO 30

VEREIN DEUTSCHER CHEMIKER (at Vienna) —Symposium The Separation of Liquids and Solids.

SATURDAY, MAY 30, 1931

Science and the Human Factor.

IN the present industrial depression there are many who regard rationalisation as on trial, and question the value of large industrial combinations It is suggested that such combinations are themselves partly responsible for the increase in the volume of unemployment, and that they tend to ignore the human factor While, however, it is freely admitted that rationalisation may and often does involve a temporary displacement of workers, the expansion in new directions which takes place as a direct result of more efficient management soon tends to absorb more than the number of workers displaced

The issue is partly obscured by the tendency in some quarters to confuse rationalisation with mere industrial amalgamation and cartels Scientific management is, however, a larger question even than rationalisation, in that it is of importance to industrial undertakings of every size, although, in theory at least, scientific management would itself initiate a policy of rationalisation if the facts in particular cases warranted it The importance of scientific management under modern industrial conditions is, however, undisputed, and valuable work is being done in this field both by the International Management Institute and by the Institute of Industrial Administration

Labour has now come to realise, to some extent, not only that science is much more than mechanical invention, and that scientific research is continually responsible for creating new industries and fresh employment, but also that under modern conditions the application of scientific methods of thought to the control of industry is of the utmost importance In spite of the fact, however, that applied science has eliminated from certain of our industries some of the grosser forms of labour which were formerly accepted as a matter of course, and that, contrary to prediction, hours of work have been decreased and not increased, the essentially humanising influence of scientific thought and method in industry is still far from being appreciated It is noteworthy, therefore, that in the scientific studies of management problems which are being carried out by the International Management Institute, the main object is to safeguard the human factor and, instead of viewing man as a piece of mechanism, as in Taylor's system, to adapt the machine to the man The selected subjects for research have included, for example, welfare devices, the selection and training of workers, and accident prevention Efficient business management to-day

and any true rationalisation policy are invariably characterised by a careful study of the human factors, which are, indeed, regarded as of supreme importance It is now widely realised that industrial efficiency cannot be attained unless the conditions of work are such as to secure the health and intelligent interest and co-operation of the workers to the maximum extent

The part played by science in securing improved and safer conditions of labour is often overlooked, but the work of the Industrial Health Research Board alone would demonstrate the importance of scientific research in this field Industrial physiology, of course, is only one section of the field of scientific management, but it is the section in which the most important modern developments have occurred During recent years, the study of industrial physiology and psychology has elaborated methods of preventing strikes and of promoting co operation between the different organisations of production, which are to-day part of the scientific organisation of labour in America These researches have the same object as the strict application of Taylor s principles in factory and workshops The success of such work is demonstrated by the changed attitude of the workers, who recognise that attempts made to increase production have become more humane and devote more attention to the human side and the health of the operators

Much of the work of the Industrial Health Research Board is only preparatory, but conclusions have already been reached which involve no revolutionary changes and, indeed, only place on a scientific and statistical basis the empirical practices of progressive firms The value of such results is demonstrated by the fact that they have already been adopted in certain branches of industry, and more widespread acceptance would greatly increase their utility For example, the American Bedaux system, which has already been introduced by a number of important firms in Great Britain, essentially incorporates the rest-pause, the value of which has been so conclusively demonstrated by the work of the Board, and settles the wage of the operative on the basis of the work he does and the compensatory rest period which should follow

In spite of the complexity of the problem presented by industrial physiology, there is no reason to be dissatisfied with the rate of progress On the contrary, the Industrial Co-ordination Committee appointed by the British Association at Bristol last year has drawn up a programme for the centenary celebrations in September which is designed to facilitate and co-ordinate the contribution of science to industry and its management The programme includes five citizens' lectures and a series of meetings to discuss such subjects as research into management problems, the training of managers, physique, posture and environment in relation to work, and the contributions of science to economy and safety in transport

This work on industrial health and conditions of work has a definite relation to the movement towards industrial safety which received so large a stimulus from the Conferences of the International Labour Organisation in 1928 and 1929, and particularly from the Industrial Safety Convention adopted at the latter Conference Industrial health is not simply a matter of securing that adequate precautions are taken in the handling of toxic materials or of dangerous machinery Science can do much to eliminate such risks, and it is well known that the accident rate in works where explosive or highly toxic substances are handled under pressures of hundreds of atmospheres or at very high temperatures is frequently below the average in industry Indeed, for every case of poisoning by gases or fumes in the chemical industry, there are twenty-five accidents caused by falls or slips

Statistics reveal that ninety per cent of industrial accidents are due to failure of the human element Such failure may be manifested in two ways In the first place, it is frequently due to ignorance of the existing dangers or of the precautions required The cleaning and repair of containers, to which a session was devoted during the recent National Safety Week in Leeds, is a pertinent example While the precautions to be observed in the handling of containers used for the storage and transport of such organic solvents as carbon disulphide, ether, benzene, and naphtha are comparatively well known in chemical industry, largely owing to its relatively high percentage of scientific personnel, they are far from being adequately known in the large number of other industries in which such solvents are widely used The large number of trade or fancy names under which solvents are sold is an added danger and is frequently responsible for the omission of precautions Even in the chemical industry itself, while the toxic and fire risks are well known, the danger of fire or explosion from the generation and accumulation of static electric charges by the flow of such solvents through pipe lines, etc , is frequently overlooked One of the most important problems of industrial safety is the handling of the mass of vital information scattered through general scientific

literature and its presentation in a convenient form for use by those concerned

A disaster like that at the chemical works at Castleford a year ago is fully investigated, but as many lives may be lost in a sequence of accidents during a year owing to a repetition of avoidable circumstances, without adequate publicity or investigation Through lack of information as to the causes of such minor explosions or accidents, casualties may occur year after year in different countries before effective means of prevention are discovered The publication, abstracting, and indexing of safety information is a formidable problem and awaits an organised attack by scientific workers, before the results of their researches can become freely available for the development of adequate safety measures in industries that are not static but continually expanding and changing as a result of scientific research

Such important contributions of science cannot entirely eliminate the human factor in accidents Not only is some slight failure of the human element—momentary neglect or carelessness—responsible for ninety per cent of industrial accidents, but also accidents are always unduly prevalent among a comparatively small number of workers The evidence shows that absenteeism due to sickness is usually abnormally high among the same persons, and that on an average they are also less skilled at their work Generally it may be said that those who are most suited to their work or environment react the most healthily to their environment, whether we measure the reaction by working efficiency or skill, tendency to sickness, or proneness to accidents

It is thus evident that vocational selection is of outstanding importance as much from the point of view of industrial safety as from that of industrial efficiency No more valuable work is being done by the National Institute of Industrial Psychology than that which it is carrying out in this field, and as a result of the application of scientific methods remarkable progress has already been made In spite of the cramping influence of unemployment on the application of some of the newer methods of vocational selection and guidance which have been elaborated, it has been demonstrated that we can at any rate avoid placing in dangerous positions those peculiarly liable to accidents, and the policy of eliminating the unfit before and not as a sequence to accidents is not utopian A classification into risk classes according to personal characteristics has already been indicated as possible

During the last century, therefore, it may be said with confidence that the whole tendency of science has been towards the amelioration of conditions of work Grosser forms of labour have been eliminated or transformed Scientific measures of protection have been elaborated which have rendered innocuous industrial processes which would have seemed incredible a generation or two ago Scientific research in industrial physiology and psychology is continually improving conditions of work so that both the health and efficiency of the worker are improved, and is now being applied to ensure that, so far as possible, young persons entering industry are fitted into occupations for which they are temperamentally suited

Such progress has inevitably improved the relations between science and labour, and those relations would become more intimate if scientific workers addressed themselves more whole heartedly to the work of education Upon their efforts the increasing expansion and application of the investigations of the Industrial Health Research Board and of the National Institute of Industrial Psychology largely depend The success of industrial safety work depends fundamentally upon the co-operation and enthusiasm of the scientific and management staff in industry Nor can the human aspects of rationalisation and its insistence on co-operation be more effectively served and fully influence industrial developments than through the power which scientific workers can exert through their privileged position in industry and their devotion to that ideal of service to which the spirit of science is kin

The Problem of Butterfly Migration

The Migration of Butterflies By C B Williams (Biological Monographs and Manuals) Pp xi + 473 (Edinburgh and London Oliver and Boyd, 1930) 21*s* net

FOR many years naturalists have known that the author was collecting material for this work, and have looked forward with great interest to its appearance His own experiences have been prolonged and varied—gathered during considerable periods of residence in Trinidad, Egypt, and the north-eastern area of Tanganyika Territory He has thus been able to compare the phenomena of migration presented by different butterflies in different parts of the world, as well as those presented by the same species during successive seasons in the same area He has also diligently collected records of migration wherever they could be found The difficulty in tracing the numberless references

to the subject must have been immense, and an exhaustive treatment of the literature in any reasonable time, impossible, for, as the author points out, "owing to the way in which they strike the general public, records of large flights of butterflies appear to be particularly frequent in popular magazines, and it is recognised that many such accounts must have been missed" He therefore appeals to naturalists for help by sending references direct to him or by publishing the data in some convenient journal under a suitable title "Few things', he writes, "are more exasperating than to discover that one has overlooked an important record of butterfly migration which was described in a popular book, 'Through Malayan Mud in a Motor', or—still more unforgivable—in a serious entomological paper entitled, let us say, 'New Diptera Nematocera from Tasmania'!" It is to be hoped that these words will receive the attention they deserve, and that the author will be given all possible help in his important and interesting inquiry

The scope and general treatment of butterfly migration in this work may be inferred from the Contents, which show that, after a brief introduction, the volume is arranged in five parts I, A preliminary discussion giving a general outline of the subject, and, in a second chapter, describing flights in progress, II, migration treated according to species, the evidence being given in ten chapters, of which the last treats of migratory moths two chapters, vi and viii, are devoted respectively to *Danaida plexippus* and *Vanessa cardui*, the chief migrant butterflies, III, migrations considered geographically—a single chapter, in which certain special areas are treated, IV, general discussion in seven chapters, dealing respectively with the nature of migratory flight, the condition and behaviour of migrants, causes of the start, determination of route and goal, comparison with other animals, general problems, summary, conclusions, and future work Part V contains an admirably full bibliography, followed by four indices on general subjects, species, countries, and authorities quoted

It will be clear from the above abstract that the work is well arranged and comprehensive, and that any one of the vast number of records which are included can be easily found It is, in fact, a rich mine of information on a fascinating subject, and this leads to the only serious general criticism of the volume The author appears to have been so intent on the admirable plan of collecting and setting before us all the available data, that he rarely 'lets himself go' on the relatively few observations which seem to be especially illuminating Thus, on the interesting subject of "Butterflies resting on the Sea" (p 342), the observations of F Muir and J C Kershaw, although conducted upon moths, certainly throw more light on this aid to migration than any of those quoted These naturalists were on a voyage from Hong Kong to Ceram, and on Nov 29, 1908, were about 190 miles S S E of the Lower Cochin China coast and about 120 miles from the Great Natunas "About 10 A M", Mr Muir wrote, "we noticed many small moths settled over the deck and all in *perfect* condition, as if just hatched At first we suspected that they were bred in the ship, but soon discovered that they were coming on board in numbers They had the power of resting on the surface of the sea—even in the broken water around the bows of the boat—and then rising and continuing their journey" Sixteen small moths belonging to four species, and including one delicate 'Plume', were collected The naturalists believed that these had flown from "the Lower Cochin China coast, and, if no bad weather turned up, would reach the various islands, and even Borneo, in fair numbers" All four species had a wide range, unaccompanied by marked local variation, over tropical Asia and the islands to the south—facts to be reasonably explained by the power of distribution in the manner described above (*Proc Ent Soc Lond*, pp xxxviii-xl, 1909) The reference to these observations is to be found in the bibliography but, unfortunately, not under the names of the observers It may be added that comparatively heavy moths can also rise in flight after coming to rest on the surface of the sea, as observed by C L Collenette in the Gulf of Panama (*ibid*, 3, p 65, 1928) That the resting place is not without danger is shown by a Hawk moth taken from the stomach of a fish in Suva Harbour, Fiji, and presented to the Hope Collection by Lieut L H Mosse-Robinson

Again, the existence of a social stimulus leading butterflies of other species to join a migrating stream, a subject briefly alluded to on p 353, appears to be proved by another significant observation made by Mr Muir, who describes "the sweeping up of the non migrating butterflies on a Papuan island when a migratory flight from another island passed over it In this instance, in which more than a single species was involved, it is evident that the social stimulus, and this alone, availed to compel the non migrating butterflies to become migrants—with such success indeed that the island was comparatively depleted of these species after the migratory stream had passed" (*ibid*, 4, p 19, 1929) In this instance the bibliographical reference omits the

observer's name and also, unfortunately, gives no clue to his illuminating observations

In the important discussion (Chapter xvi) of the conditions determining the start of a migratory flight it would have been well to refer back to pp 96 and 97, where observations on the overcrowding of Pierine breeding-places are quoted—those of Robinson in India and Pitman in Uganda—or even better, to have quoted or transferred the relevant passages The words of the last-named naturalist might also with advantage have been added to the quotation on p 97—" It struck me at once that such a breeding area must most certainly be the source of some of the numerous Pierine migrations so frequently witnessed in this part of Africa " (*ibid*, 3, p 45, 1928) The suggestion of a perennial source is also supported by the fact that the butterflies sent home were shown by their small size to have been starved, and that similar dwarfed specimens had been received two years before from a migratory flight of the same species encountered far to the south of the great breeding-ground in the West Nile Province (the old Lado Enclave) so graphically described by Pitman (*ibid*, p 46) Referring to the overcrowding witnessed by Robinson and Pitman, the author writes on p 97 "There is little doubt that it is from such mass breeding areas that flights start, but apparently in both these cases conditions were not, or had not been, suitable for bringing about a migration If one such area could only be watched for a continued period we might learn much as to the origin of migration " Until such prolonged observations can be carried on, we shall rarely be offered the direct evidence of flight from an overcrowded area Occasionally, however, by a happy accident a naturalist has been present at the critical period Thus, Sir Guy Marshall has recorded that the migration of another Pierine butterfly (*Catopsilia florella*) was actually taking place from a Rhodesian valley where the conditions were those described by Robinson and Pitman (*ibid*, p xiv, 1921) Here, too, it would have been well if this brief but important record had been quoted and referred to in the bibliography under the name of the observer

A few points of systematic interest and a good many mistakes in the spelling of names, although but a very small proportion of those which appear, will require adjustment in a later edition Thus, *Danaida plexippus*, the great North American 'Monarch' which has spread to so many parts of the world, is treated on p 149 as if it were the same species as a much smaller Danaine, the Oriental *D genutia* Although the two butterflies are closely related and the latter represents the Old World ancestor of the former, there can be no doubt that they are *now* entirely distinct *Libythea*, which has unfortunately given its name to a sub-family (Libytheinæ) of the Erycinidæ, as shown on p 242, has now been removed from this family and placed among the Nymphalidæ The following mistakes in spelling were noted *limniacea* for *limniace* (36, 80), *camadera* for *camadeva* (40), *erithronius* for *erithonius* (49, 460), *Pinacopterix* for *Pinacopteryx* (99), *gidaca* for *gidica* (105), *aglaiœ* for *aglaia* (116), *napae* for *rapae* (125), *Synchlœ* for *Synchloe* (126), *Telechinia* for *Telchinia* (240), *andromycha* for *andromache* (240), *Cymathœ* for *Cymothoe* (285, and *œ* elsewhere), *Sarangesia* for *Sarangesa* (401), *berenica* for *berenice* (403), *vitelline* for *vitellina* (408) These collected errors will create an unfair impression unless it is remembered that they are very few as compared with the great number of names printed in the volume Nearly all the verified references were found to be correct, although "Carpenter " did not appear on page 137, given in the index Also, the reference on p 354 (l 8) to a publication in 1922 should have been given as 1921, correctly quoted in the bibliography

The preparation of this most valuable work has been an immense labour and its appearance will lead to rapid advance in our knowledge of the subject, leading to that noble fate which the late G H Verrall described in arresting words "The finest monograph is the one which will be soonest out of date!"

Robert Hooke

Early Science in Oxford By R T Gunther Vol 8 *The Cutler Lectures of Robert Hooke* Pp vii + xii + 391 + 18 plates (Oxford The Author, Magdalen College, 1931) 25s

ROBERT HOOKE was an Oxford man, for he was a servitor at Christchurch, and an assistant to Boyle there, before he came to London to work for the newly founded Royal Society Hence the appropriateness of this volume, which might otherwise escape us, for Hooke, living all the best known period of his life at Gresham College, as Gresham professor, and as Curator of Experiments to the Royal Society, as surveyor of the City of London and architect of some of its buildings, even as a Westminster boy, seems essentially a Londoner

The Cutler Lectures, which were founded to give Hooke "wherewith to scolay ", offered an occasion for him to publish his many sided ideas As

Dr Gunther says, the volume in which they are collected has now become exceedingly rare Hence he has reproduced the whole in facsimile, or nearly in facsimile, for, though every page and diagram has been photographed, there is almost as wide a difference in flavour between this book and the original of it as there would be between the original Robert Hooke and a modern waxwork image of him Still, we have Hooke's words, and they deserve some attention, for he was a very remarkable man, and has passed into the history of science as a jealous and querulous claimant for originating discoveries that other people perfected

It is quite possible that Hooke was a difficult man in his personal relations, but there is nothing in this volume to justify the reputation that has clung to his memory so persistently His mind was one of extraordinary fertility, and there seems to have been no branch in the seething physical discoveries of the second half of the seventeenth century in which he did not mingle, and to which he did not contribute Hence he usually found himself in competition with others, but even in the controversy with Hevelius on the advantage of using optical aids to enhance the value of the divisions of an astronomical instrument, he was not only right, but also appears to have written no word that was less than civil or that one would wish to withdraw Nor, in saying so, need we allow for the somewhat ferocious manners his times permitted Everyone knows that he was inventive and industrious, but not everyone that he wrote as a man of careful, judicious type, who knew exactly where theory ended and what could be done with the practical resources then at command

Hooke's misfortune was that he covered the whole field of scientific curiosity, and that in every branch of it there were better, if more limited, men than he He was a good astronomer, but Hevelius and even Flamsteed were better He appears to have been a beautiful mechanic, with a fine sense of design, but the brothers Constantine and Christian Huygens were even finer He was a distinguished architect, but not to be mentioned with Wren Finally, he had a penetrating insight into physical theory, only to be utterly outclassed by Newton

'Hooke's Law' for the restitutive force of springs, with its application to the production of synchronous watch balances, and the bending moment for beams, we find here Though many of the other matters are controversial, and need not now concern us, possibly the most remarkable of his anticipations is that contained in the first of these lectures It is largely unknown, because its outcome was negative It is a search for stellar parallax, as a practical verification of the Copernican theory, such as afterwards led Bradley to the discovery of aberration, and it is conducted on exactly the same star, γ Draconis, and by exactly the same method, a fixed vertical telescope It was carried out with all the thoroughness and forethought and skilful design that would have ensured success, had it been anywhere within reach

Surveying Methods

(1) *Applied Aerial Photography* By Capt Ashley C McKinley With a Chapter on Oblique Aerial Surveys (Canada), by A M Narraway Pp xiv + 341 (New York John Wiley and Sons, Inc , London Chapman and Hall, Ltd , 1929) 25*s* net

(2) *La topographie sans topographes traité de photogrammetrie* Par F Ollivier Pp xviii + 301 (Paris Éditions de la *Revue d'Optique theorique et instrumentale*, 1929) 42 francs

(3) *Mesure optique des distances et methode des coordonnées polaires avec etude spéciale du tachéomètre auto reducteur Bosshardt Zeiss* Par Rodolphe Bosshardt Traduit par Prof Maurice Delessert Pp 172 (Geneve Georg et Cie, 1930) n p

(1) THE title of the first of these books is ill-chosen The subject is the technique of air photography for topographical purposes There are brief excursions into map reading and plotting, but they, like the bibliography, are but notes by an amateur for amateurs On the other hand, the technique of flying, photographing, developing, indexing, 'mosaicing', and the like, shows the hand of an experienced and practical man Mr McKinley knows his own subject He is an enthusiast, for he thinks that the "*exclusive* use of ground surveying will become obsolete" On the other hand, he realises that "no one factor has retarded advancement so much as the assertion of exaggerated claims" He writes for an American audience, describes American aircraft and cameras, and uses such words as "restitution" (of air photographs) and such expressions as "dividing the polyconic projection into rectangles". Enough has been said to show that Mr McKinley's book will be a useful one for pilots and photographers, but of small value to the surveyor who has to apply these photographs to his map-making

A final chapter by Mr Narraway, Dominion Land Surveyor of Canada and Aerial Surveys Engineer,

describes the perspective grid (oblique photograph, small scale) mapping method, originally suggested by the late Dr Deville and used with such success in the mapping of the Laurentian Plateau

(2) Commandant Ollivier deserves our thanks He deals with ground photo surveying—from Laussedat and Deville to Van Orel, and from photogrammetry to the stereoautograph—and he promises another volume to deal with air photo survey History, instruments, precision, errors, methods, processes, and results are all as clear and logical as one expects from the best French books It is perhaps not very important that the author's lack of interest in foreign methods and personalities is equally French

This is, for its compass, the clearest guide to the subject which has appeared It is all to the good, too, that Commandant Ollivier is an enthusiast The comparisons with ground methods are, however, exactly on a parallel with those of Deville Neither the one nor the other knows how small scale topography should really be done But that is not the point Anyone who wants the theory and practice of photo surveying can get it from this book, and will be very interested , but let him remember two points which are not brought out First, you cannot survey if you cannot see, and therefore you cannot use photo surveying in a forest or in a flat country of hedgerow timber , and secondly, photographic methods are essentially medium scale They offer little, if any, advantage to the property surveyor or the small scale topographer

(3) Here we have a Swiss book on a third, equally important, aspect of surveying, that of optical methods of measuring distance—methods which lend themselves obviously to a subsequent plotting by polar co-ordinates British surveyors of the past were content to class tachymetry as a method giving, roughly, errors of the order of one part in five hundred Modern telemeters (for which the base, or graduated staff, is held horizontally, thus escaping the troubles of unequal refraction) have greatly increased its possibilities Were Great Britain faced with original property surveying at the present time, there is no doubt that optical measures would be given their chance, and engineers and other large scale surveyors will do well to explore their possibilities

Mr Bosshardt's book is well designed, clear, and definite in its analysis of errors and description of instruments, and those who read French with greater facility than German will find excellent reading in Prof Delessert's translation

Our Bookshelf.

A List of Official Chemical Appointments compiled by direction of the Council of the Institute of Chemistry and under the supervision of the Publications Committee Seventh edition, revised and enlarged Pp 402 (London Institute of Chemistry, 1931) n p

"OFFICIAL Chemical Appointments ", now in its seventh edition, has firmly established its right to a place on the most accessible shelf of the chemist's library Moreover, since it catalogues the personnel of professional chemical services in connexion with State and municipal administration, it is consulted with increasing frequency by official, educational, and commercial authorities The new edition of some 400 pages, compiled under the auspices of the Institute of Chemistry, is divided into four parts The first gives information concerning the activities of official establishments employing chemists in the British Isles, with a list of holders of the appointments (with degrees and universities) In this section are found, for example the universities and schools, Government departments, water boards, industrial research associations, the National Physical Laboratory, public analysts, etc , and similar appointments in Northern Ireland and the Irish Free State In the second part, appointments in the Empire overseas are recorded

The third portion deals with societies and institutions, briefly referring to their objects, regulations for admission, etc , as well as mentioning the names of their officers The fourth section contains a list of acts of Parliament, orders, regulations, etc , affecting official chemical appointments, and is followed by indexes of names and places, unfortunately marred by long errata lists arising from the printer's oversight Subsidiary to its real utility as a book of reference are the pleasure which one may find in a study of the movements of one's former colleagues and acquaintances and the interest to be derived from the unexpected association of names with places

God and the Universe Eddington, Jeans, Huxley and Einstein By Chapman Cohen With a Reply by Prof A S Eddington (Issued by the Secular Society, Ltd) Pp 133 (London The Pioneer Press, n d) Paper, 2s , cloth, 3s

THE issues raised in this book are too important to be discussed casually in a few lines The relation between religion and science is, of course, a very old problem But the amazing developments of physical theories are apt to give a new setting to it When scientific workers find themselves in a philosophical mood, they indulge in offering their readers some tentative suggestions about the theological extension of their particular science So we get Eddington's scientific approach to religion, Huxley's religion without God, Jeans's mathematical God, and perhaps Einstein's Spinozistic God Philosophers should be thankful to men of science for such indications , the more so as they are not forced upon one by their authors with the same mental pressure often displayed by

metaphysicists Because scientific workers do not present their conclusions in this respect as binding and final, philosophers must return the courtesy and treat them, for example, in the same dignified spirit as that shown in Sir Arthur Eddington's reply to Mr Cohen's criticisms His case would have been perhaps stronger if Mr Cohen had shown more modesty and less partisanship in his statements and in his professional defence of materialism and free thought But when he starts off by proclaiming that after his criticisms of " very many " books by scientific workers aiming at reconciliation of science and religion, their authors decided generally that " discretion was the better part " and that " silence in their case spelt safety ", one may pertinently wonder whether Mr Cohen should be taken as a safe guide in philosophy, and whether he is qualified to pay compliments to that section of the Christian clergy whom he denounces as " dishonest " for acclaiming these men of science as being witnesses on behalf of God T G

Acoustics of Buildings including Acoustics of Auditoriums and Soundproofing of Rooms By Prof F R Watson Second edition, revised Pp x + 155 (New York John Wiley and Sons, Inc , London Chapman and Hall, Ltd , 1930) 15*s* net

It is not a great many years ago since the satisfaction of acoustical requirements was purely a matter of empiricism Here and there a scientific worker such as Rayleigh could explain the underlying principles , but seldom could an acoustic triumph, like the Free Trade Hall, Manchester, be acclaimed, nor could dependent data be obtained even from that , consequently, neither analysis nor synthesis came to our aid and architects were but blind leaders of the blind Wallace Sabine, however, introduced a new era into acoustical research, and now it is by no means uncommon to secure success Prof Floyd Watson's treatise is a welcome contribution to the synthetic treatment of the subject Whether it is better to secure original acoustic satisfaction or to correct acoustic failures, admits of no argument In either case, the author's work has the merit of showing the way The value of wires and sounding boards is almost entirely discounted in the light of modern investigation The concluding argument is interesting, in its recommendation that Sabine's advice (remembering the varying size of the audiences) to effect a compromise, is the desirable procedure For practical purposes the use of the different sound absorbing coefficients is of the greatest value

P L M

The Annual Register a Review of Public Events at Home and Abroad for the Year 1930 Edited by Dr M Epstein (New Series, Vol 172) Pp xii + 313 + 176 (London, New York and Toronto Longmans, Green and Co , Ltd , 1931) 30*s* net

The new issue of this useful book follows the usual plan of arrangement, which, combined with a detailed index, make reference easy The bulk of the volume records the political and social history of Great Britain, the Empire, and other countries The summaries are both full and readable, and omit no matter of importance in any part of the world The second part is devoted mainly to retrospects of literature, science, art, law, and finance during the year

Science has ten pages for its share, divided between the biological sciences, including anthropology, and the physical sciences Much interesting matter and many broad views are crowded into these pages, and some of the more important books of the year are mentioned The public document printed in full this year is M Briand's memorandum on the organisation of a regime of European Federal Union, with the report by the French Government on the inquiry The volume concludes with biographical notes of eminent persons who died during the year

Number the Language of Science By Prof Tobias Dantzig Pp xi + 260 + 11 plates (London George Allen and Unwin, Ltd , 1930) 10*s* net

The author of this interesting book has achieved a difficult task with much distinction, in showing that number, which is considered as the ' driest ' topic on earth, could be made the basis of a profoundly human story From the use of finger-prints to the invention of transfinite numbers, we are told how the theory of numbers, born in religious mysticism, has passed through a period of erratic puzzle solving before it acquired the status of a science Yet the book is not a technical history of the subject , so that it should interest not only mathematicians but also the wider circle of those who like to ask themselves how science has come about Symbols are scarcely used , but the historical method has been freely introduced to bring out the rôle intuition has played in the evolution of mathematical concepts This novel and pleasant presentation of an intricate subject is a great credit to its author T G

L'Art nègre à l'Exposition du Palais des Beaux-arts du 15 novembre au 31 décembre 1930 Par J Maes et Dr H Lavachery Pp 32 + 48 planches (Paris Les Éditions G Van Oest, 1930) 30 francs

This book, primarily a guide to the section of Negro art in an exhibition held at Brussels at the end of 1930, consists of two brief but adequate essays on the main characteristics of African art M Maes deals with the sculptural art of the Belgian Congo, and Dr Lavachery with that of the remainder of Africa a not unfair division of labour in view of the importance of the Congo as an art centre It will be remembered that from here came the wooden statuettes which have had such a marked effect in modern European art and æsthetics The plates figure a large number of examples Excellent as is the text within its limits, the plates alone make this something more than a mere guide-book and worthy of permanent preservation

Letters to the Editor.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE *No notice is taken of anonymous communications*]

Atomic Weight of Cæsium · Use of the Word 'Mass-spectrograph'

THE first mass spectra obtained from cæsium by means of a hot anode showed only one line of mass number 133 As I pointed out,[1] the conditions of the experiment precluded any accuracy of measurement sufficient to decide whether the chemical atomic weight then and since accepted, 132 81, did or did not represent the weight of the atom Quite recently, K T Bainbridge,[2] using Dempster's method of analysis, has confirmed the simplicity of cæsium to such a degree as to make him confident that no other isotope exists to the extent of 0 3 per cent As he points out, on this view the atomic weight of 132 81 would imply a packing fraction of − 14 3 Such a figure would be so completely abnormal that it seemed desirable that it should be tested by direct and trust worthy means

The obvious method is to photograph Cs 133 be tween Xe 132 and 134 To be really convincing, the lines must be produced during the same exposure, and as the alkali metals and the inert gases are, from the point of view of mass ray technique, the extreme and mutually exclusive types of element, this is by no means easy After many trials, I have now succeeded in making a form of discharge tube capable of pro ducing the anode rays of cæsium at the same time as the gas rays of xenon Furthermore, by varying the quantity of the latter element present and the times of exposure, mass spectra have been obtained which enable the masses to be compared with an accuracy of 1 in 10,000 The results are conclusively against any abnormality If we assume the packing fraction of xenon to be − 5 3 ± 2 0, as already determined, that of cæsium is − 5 0 ± 2 0, the weight of the cæsium atom ($O^{16} = 16$) is 132 933, and using Naudé's factor of 1 25 in 10,000 to transform to the chemical scale we get

At Wt of Cæsium = 132 91 ± 0 02

In further reference to Bainbridge's letter, I should like to lodge an objection to his application of the word 'mass spectrograph' to Dempster's form of analysis This word I coined in 1920 to describe an instrument which by its peculiar sequence of electric and magnetic fields eliminated the effect of varying velocity and gave a spectrum dependent upon mass alone Dempster's apparatus, described two years earlier, is essentially an application to the analysis of positive rays of the well known and widely used principle of semicircular magnetic focusing Such an instrument gives a magnetic spectrum which depends upon momentum and not upon mass *per se* The fact that it is the standard method for determining the energies of beta particles makes this sufficiently obvious The use of the word mass spectrograph, unqualified in any way, to an apparatus not using in any manner the principle implied in it, appears to me to be a misleading and undesirable practice

Petroleum and Alpha Radiation.

IN NATURE of Feb 28 (127, p 317) reference was made to my recent address before the American Association for the Advancement of Science,[1] as reported by Science Service Lest the 'novelty' of the possible rôle of alpha radiation in the interaction of hydrocarbons in the earth's crust obscure its true relative importance, I should like to make a further communication and to suggest a new way of accounting for the absence of free hydrogen in natural gases

In the first paper of Lind and Bardwell on the action of alpha particles on saturated hydrocarbons,[2] it was pointed out that similar reactions *must* take place in the earth's crust if conditions exist where alpha particles bombard hydrocarbons While these conclusions were then based on experiments with gaseous hydrocarbons, there was indirect evidence that the reactions extend also to the liquid members More recent work by W T Richards[3] in the laboratory of Sir Ernest Rutherford gave direct proof that this is true not only for liquid but also for solid paraffins and that hydrogen is the principal gaseous product Calculations from Richard's results[4] showed that even the quantitative yield of hydrogen per ion pair is certainly not less than half of that in the gases

Hydrogen is therefore the most abundant gas produced by the reaction, and since Lind and Bardwell had shown[5] that it does not interact further with unsaturated hydrocarbons under alpha radiation, it becomes an important criterion of reaction unless it is removed in some other way

The fact, however, that free hydrogen is conspicuously absent in natural gases (except in some volcanic regions) led us to conclude that the problem of its disposal must be met before even a partial radioactive origin of petroleum could be accepted Under catalytic conditions which are quite possible, hydrogen could recombine with liquid unsaturates, but this would account for less than half of it, assuming the initial hydrocarbons to have been saturated, since all the hydrogen liberated in condensation to higher saturates would still remain free

If, however, the original hydrocarbon (or hydrocarbons) be assumed to have been unsaturated (or if unsaturates have been produced from saturates by the thermal elimination of the necessary amount of methane), the complete catalytic removal of hydrogen under high pressure and high temperature conditions becomes possible, because the amount of hydrogen liberated by alpha rays is much smaller from the unsaturates—far less than the amount required for saturation Moreover, we do find petroleum to contain unsaturated members, possibly indicating an initial excess of unsaturation

Although this suggestion as to disposal of the hydrogen may be regarded as making the radioactive origin of part of our petroleum more probable, the abundance of methane in natural gases associated with petroleum seems to indicate that the *thermal* interaction of hydrocarbons at high pressures and temperatures suggested by Prof H A Wilson[6] is perhaps the more prolific source of petroleum, since, according to his theory, *methane* would be the lower terminal member

The recent note on this subject in NATURE also raised the pertinent question " is radioactivity a potential function in the type of environment and at the comparatively shallow depth in the crust which modern views seem now to imply for the birth of the oil globule ? " It scarcely appears possible to answer this question definitely, but certainly we would not be justified in a negative answer The distribution of a low radium content in the earth's crust is so general and so constant that its action extended over

The state of polarisation of the Raman lines has also been studied with the gases carbon dioxide and acetylene It is found that the strongest lines ascribable to a linear vibration of the molecule are nearly completely polarised The 'wings' appearing on either side of the exciting mercury lines, which represent the rotational Raman spectrum, are, however practically unpolarised, as is to be expected from the theoretical work of Manneback [5]

Forestry Research in Great Britain

I SHOULD like to support the plea put forward in the recent article on forestry research in Great Britain (NATURE, May 16 p 729) that the Forestry Commissioners should in future take greater cognisance of research on the basal problems of pure science that underlie successful afforestation As chairman of the Research Committee of the British Association which has been the means of providing Dr M C Rayner with a small measure of assistance for her researches on tree mycorrhiza, I have been brought into intimate contact with one of the fundamental problems that concerns the establishment of forests on land hitherto devoid of trees I have been greatly impressed with the urgent need for more adequate facilities for this work than can be provided by the very limited funds of the British Association, and I venture to express the hope that the Forestry Commissioners will give sympathetic consideration to the desirability of assisting these investigations

The Form of Fæcal Pellets and Specific Identification

IN the differentiation of closely allied species, any additional character which may help to separate them will be of value In the case of ascidians, for example,

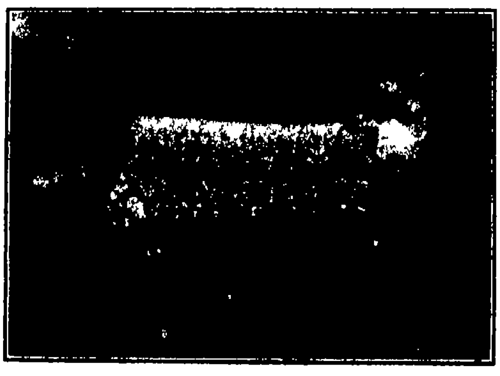

FIG 1 —Fæcal pellet of *Gibbula magus*

much help is obtained from the nature of the eggs A character, however, which has not previously been made use of is the nature of the fæces While in many cases these are either shapeless or else of very variable shape, a large number of animals have fæces of a quite distinctive type The specific character of the fæcal pellets may lie either in differences of their general shape or else in details of surface sculpture, the latter often being exceedingly elaborate, as in the example shown in Fig 1

While we have as yet investigated the fæces of only a limited number of species, the following examples of some of the animals which may be thus differentiated is suggestive of the value of the method *Nucula nitida*, *N nucleus*, *N sulcata*, *N tenuis*, *Syndosmya alba*, *S nitida*, *Gibbula cineraria*, *G magus*, *Calliostoma zizyphinus*, *Cantharides clelandi*, *Acmæa virginea*, *A testudinalis*, *Ascidea venosa*, *Ascidiella scabra*

We hope to give an account of some of these fæcal pellets in the near future, but meanwhile we suggest the value of examination of fæces, to those requiring additional characters for the definition of species

Flint Implements of Lower Palæolithic Types from Northern Ireland

DURING a recent visit to Northern Ireland, one of us (J P T B) found in gravel lying between two Boulder Clays exposed in the valley of the River Carey, and in glacial gravel in the Dun valley, in Co Antrim, a series of flint implements of Lower Palæolithic types Other examples of these specimens, easily distinguishable by their forms, condition, and flaking from later artefacts, as well as from naturally flaked stones, were also discovered in certain post glacial gravel spreads of these two rivers

The ancient implements referred to are derivatives in both series of deposits, and their true antiquity is, from a geological point of view, therefore, unknown An examination of the specimens, however, demonstrates that they comprise forms which at other sites, in East Anglia for example, are recognised to be of Early Pleistocene date As is known,[1] at this epoch, over very wide areas of the earth's surface,[2] the evidence is clear that ancient man was engaged in making coarsely flaked hand axes by means of a skilful development of the earlier rostro carinate implements It is, therefore, of considerable interest and importance to observe that these newly discovered specimens from Northern Ireland comprise coarsely flaked hand-axes of rostroid forms, and rostro carinates

The manner in which these implements were made in Ireland is precisely similar to that in which others were formed during the epoch of the Cromer Forest Bed of East Anglia, in Palestine, in South Africa, and in India In view of this significant fact, we feel justified in claiming that flint implements of Lower Palæolithic (Early Chellean) types have now been discovered in Northern Ireland, and we propose in the near future to publish a detailed account of this discovery It is well also to recall that, many years ago, the late Mr W J Knowles claimed to have found Palæolithic implements in the so called 25 ft raised-beach of Northern Ireland The majority of these specimens, of Palæolithic forms, one of us (J P T B) would, however, not accept as of this antiquity, though we consider it probable that a few of them are to be relegated to Palæolithic times

The Peking Skull *

By Prof G ELLIOT SMITH, F R S

WITH characteristic promptitude, Prof Davidson Black has now provided us with a full report upon the features of the Peking skull, giving a detailed description of its external form, illustrated by 16 photographic plates (each photograph provided with a transparent explanatory drawing) and 37 text figures The drawings represent exact orthogonal projections not only of the type skull but also of the second skull of *Sinanthropus*, the finding of which was discussed in NATURE of Aug 9, 1930 (p 210), and of a series of other fossil human skulls The purpose of this comparison is to define the distinctive characters of *Sinanthropus* and to emphasise the contrasts in size and proportions that differentiate it from *Pithecanthropus* and the series of Neanderthal skulls An elaborate series of measurements is provided, together with a statistical analysis of the significance of the figures, in comparison with those of other fossil human types, as well as of representatives of modern races of men Hence complete data are now available to enable the anthropologist to realise the distinctive features of the Peking skull and the reasons which induced Prof Davidson Black to differentiate it from all other known human types and assign it a distinctive generic rank

The history of the finding of the skull by Mr W C Pei on Dec 2, 1929, has already been told in NATURE (Mar 22, 1930, p 448) It was not until four months later that Dr Black completed the process of removing from the surface of the skull the hard mass of travertine in which it was embedded He then began to make casts and photographs of the specimen and to prepare the preliminary reports After this was accomplished, he set to work to expose the interior of the skull, and in this he was inspired by the motive of preserving if possible the natural endocranial cast Fortunately, this was possible because the braincase was fractured, enabling the bones to be removed piecemeal Moreover, the skull is that of a young adolescent, whose age, in Dr Black's opinion, corresponds to that of a modern child between the time of eruption of the second permanent molar teeth and the attainment of adolescence, say 15 ± 2 years Thus it was possible easily to disarticulate the constituent bones This work lasted until well into the summer of 1930, when Dr Black succeeded in removing the cranial bones from the surface of the endocranial cast and then reconstituted each individual bone, and eventually rearticulated the skull with more precision than it had at the time when it was found Before doing so, however, he made photographs and models of each separate bone, and took X ray photographs to display the sinuses and other details in the texture of the bones, such, for example, as the labyrinth in the temporal bone Then the skull was rearticulated and an artificial cast made of the cranial cavity

The present monograph describes the external surface of the skull and each individual bone The description of the endocranial cavity and cast which Prof Davidson Black has obtained of it will be discussed in a second monograph that is now in course of preparation

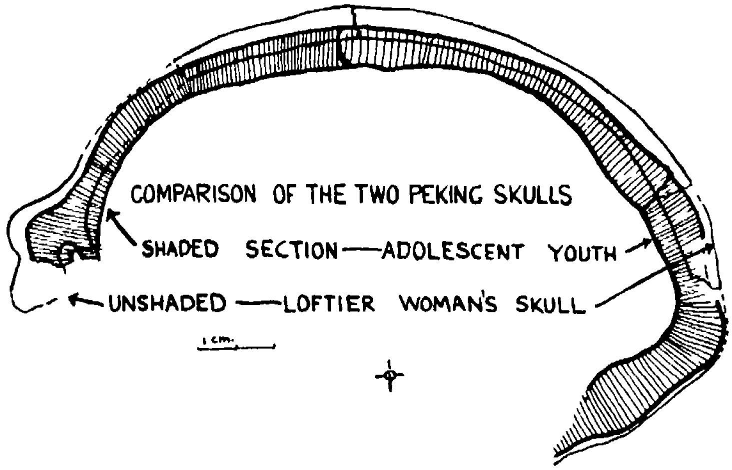

FIG 1 —Median longitudinal projections of the Peking skulls × ½

In July 1930 a large part of a second braincase was obtained from certain blocks of limestone which had been brought into the laboratory in October 1930 In his monograph Dr Black gives full details of the comparison of the two skulls and the evidence upon which he relied to interpret the sexual characters and ages of the two individuals The skull obtained in December 1929 he now regards (for reasons set forth in full in this report) as that of a youth in a stage of development between puberty and adolescence, and the second skull that of a woman Partial obliteration of the left side of the coronal suture suggests that the latter was an adult, possibly more than ten years older than her companion In the accompanying diagram (Fig 1) Prof Davidson Black's drawings of median longitudinal projections of the young skull (shaded) and of the adult (female) skull have been superimposed The female skull is slightly thinner than that of the youth and is also larger, being somewhat higher and longer than the male skull (Fig 1) and presenting other differences which are probably expressions of the difference in sex

In view of the claims put forward by certain writers that the Peking skull should be included in the genus *Pithecanthropus* or, alternately, in the species *H neanderthalensis*, Prof Black has devoted a large amount of attention to the comparison of

* Davidson Black, On an Adolescent Skull of *Sinanthropus Pekinensis* in Comparison with an Adult Skull of the same Species and with other Hominid Skulls, Recent and Fossil', *Palæontologia Sinica*, Series D, vol 7, Fascicle 2 (Peiping Geological Survey of China, Peiping, April 28, 1931)

the projections of the skulls of *Pithecanthropus* and the various representatives of the Neanderthal species By means of statistical comparisons he has made out a conclusive case in justification of the necessity of making a new genus and species for the reception of the Peking skulls

While it is evident that the crania of *Sinanthropus* and *Pithecanthropus* resemble one another (Fig 2) much more closely than they do any other human type, it is no less certain that they differ from one another in point of size, proportions and detail to a degree amply sufficient to proclaim their generic distinction It is a remarkable fact, Prof Black adds, that in all its cranial parts *Pithecanthropus* shows ' evidence of an archaic specialisation in marked contrast to the evidences of archaic generalisation so abundantly preserved in the crania and teeth of *Sinanthropus* " In other words, the apparent primitiveness of the Java fossil is in part probably due to degenerative changes responsible for the uncouth shape of the skull, which presents so striking a contrast to the elegant and undistorted braincase of the Peking man Apart from its massive supraorbital torus and reduced third molar tooth, the Peking skull presents no highly specialised features On the contrary, its general proportions, the morphology of the teeth, and the features of the tympanic and other individual elements of the skull, all provide evidence that *Sinanthropus* was a generalised and progressive type

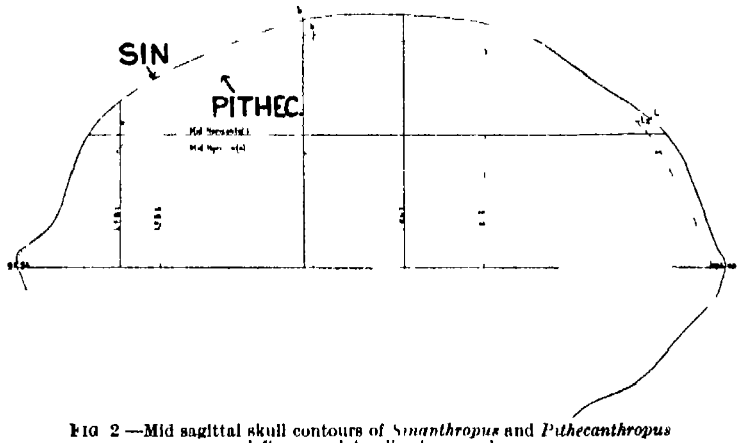

FIG 2 —Mid sagittal skull contours of *Sinanthropus* and *Pithecanthropus* left norma lateralis view ½

Prof Black does not devote much attention to the comparison with the Piltdown skull The purpose of the present work is to provide anthropologists with a detailed description of his specimen and an exact comparison with other specimens of unquestioned and generally recognised authenticity For this reason, as well as to avoid partiality, he uses the data collected by Dr H Weinert in the case of *Pithecanthropus*, based upon the study of the actual fossil, with information provided by Prof Dubois in amplification Similarly, for the Neanderthal skulls Dr Black relies on the data and figures provided by Dr G M Morant As, unfortunately, there is still considerable doubt in the minds of many anthropologists concerning the Piltdown skull and the mode of its reconstruction, Dr Black does not make much use of it for comparison He does, however, emphasise the fact that the peculiarly developed postero-inferior parietal boss in the Peking skull resembles in certain important features the similar, if less obtrusive, development of the Piltdown parietal He also directs attention to the similar thickness of the skull in the genera *Sinanthropus* and *Eoanthropus*, but points out that the range of unevenness in thickness of the Peking skull presents a marked contrast to the more uniform Piltdown fragments

Although Dr Black himself has refrained from instituting detailed comparisons with the Piltdown skull, it is interesting to compare (Fig 3) the transverse section he provides of the skull of *Sinanthropus* (the thick lines) with a section made in the corresponding plane (auditory meatus) of the reconstruction of the Piltdown skull (the larger shaded area) made by the late Prof John Hunter This section, like the view of the two skulls from the posterior aspect, brings out the essential identity of their architectural plan in a most striking way, and reveals a similarity of form and proportions which is unexpectedly close Apart from the difference in thickness, the adult skull of *Sinanthropus* approaches even nearer to the Piltdown skull in some respects Thus (see Fig 1) it is loftier than the type skull and its height is identical with that of *Eoanthropus* but the latter is considerably wider and correspondingly more capacious

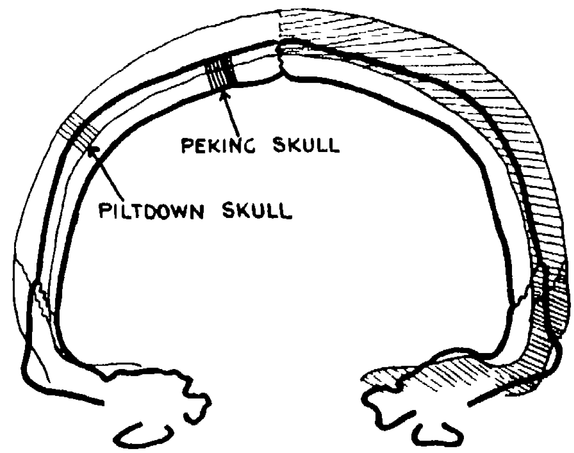

FIG 3 Transverse sections of Peking and Piltdown skulls × ½

The general form and proportions of the Peking skull, as well as the details of many of its constituent parts, are surprisingly modern in character The man of China was clearly a very primitive and generalised member of the human family close to the main line of descent of *Homo sapiens*

Prof Black devotes particular attention to the unique character of the temporal bone, which presents a marked contrast to that of all other known men and apes Of special interest are the distinctive features of the tympanic and mastoid portions,

showing, not only in the case of the mastoid but also in the form of the auditory meatus and middle ear, characters which in modern man occur only in new-born infants and very young children—a widely open meatus terminating at an ear drum the inclination of which closely approaches the horizontal This state of affairs is lost in *Homo sapiens* long before the age of puberty is attained As Dr Black remarks, the features of the tympanic region of *Sinanthropus* are admirably suited to serve as a starting-point for phylogenetic speculation "With this generalised type before us it is not difficult to imagine developmental stages through which such an element in a stem-form may well have passed, leading to the modifications such as are characteristic of the Piltdown, Neanderthal, and modern men" On the other hand, since all the essentials of the tympanic morphology of the great anthropoid apes may be recognised in these elements of *Sinanthropus*, a comparison of the latter may serve to indicate in some measure the degree of their divergence from a common type In spite of this provocative comment, Prof Davidson Black refrains from discussing the intriguing problems he mentions He does not depart from the admirable restraint that characterises all he has written upon this subject, which makes his monograph a reliable guide to those who want the data and prefer to form their own opinions as to their meaning

The great importance of the discoveries in China lies in the fact, not only that the material is more abundant than the remains found at Trinil and Piltdown, and their geological age is unquestionable, but also that, while *Sinanthropus* is differentiated from the genera *Pithecanthropus* and *Eoanthropus*, it is much more generalised than either, yet definitely linked to both While it is the most primitive type of human being so far discovered, its structural affinities with both the Javanese and the British genera link together all the known types of Pleistocene men and give cohesion to our knowledge

It is fortunate that the information concerning this unique material has been so fully and so promptly supplied to anthropologists in a monograph which is distinguished by admirable clearness and impartiality Once more Prof Davidson Black deserves our congratulations on a great achievement

The Spicer-Dufay Process of Natural Colour Kinematography.

By T THORNE BAKER

ALL modern attempts to reproduce by photography the natural colours of a subject depend upon some method of three colour analysis The theory that by the admixture, in various proportions, of blue-violet, green, and orange, any colour in Nature can be imitated, has been adequately borne out by practical experiment So-called 'two-colour' processes must at the best be regarded as crude attempts to saddle each of two of the primaries with one half of the third

Methods of photography in which a glass support is coated with a mosaic or matrix of tiny coloured areas of the three primary colours, and then with a photographic emulsion, are well-known Such material is exposed through the coloured mosaic, so that the light rays are microscopically analysed before reaching the sensitive emulsion It is then developed, and after the black developed image has been dissolved away, the previously unexposed silver salts are exposed to light and themselves developed and blackened in turn This procedure gives a positive transparency image, and if it be viewed by transmitted light—that is, through the coloured matrix on which it lies—the original picture will be seen in its original colours To A and L Lumière belongs the credit of having first issued such a material (1907), it is still known as the Autochrome plate, and is still largely used

Motion picture photography based on the same fundamental idea has proved vastly more complicated The coloured mosaic necessarily absorbs a very high proportion of the incident light, and corresponding increase in exposure is required With the advent of 'talking pictures', the old speed of sixteen pictures per second in kinematography has been raised to twenty-four, and with the best shutter mechanism this means that no more than 1/40 second can be allowed for each individual exposure Hence quite apart from the immense improvement in large aperture lenses which has come about in recent years, it has been necessary to produce panchromatic emulsions of extremely high sensitivity

The films exhibited on May 20 at the conversazione of the Royal Society at Burlington House were procured on a new film which has been developed during the past four years in the research factory of Messrs Spicers, Ltd, at Sawston, Cambridgeshire The film base itself, which is made at Sawston, is of the acetate type, and is non-inflammable in the strictest sense By a combination of new plasticisers with a novel method of maturation, a film has been produced which retains its suppleness and whiteness indefinitely So rapid is the maturing that the base can be used for photographic purposes a few hours after it has been cast

The base is coated with a very thin layer of collodion containing a green dye of the necessary concentration to act as a primary green filter It is then passed through a rotary printing-press of special design which impresses upon it 375 parallel ink lines to the inch, with the same number of intervening clear spaces It is next passed over rollers through a bleaching bath, which decolorises the green dye where it is unprotected by the greasy lines of printing ink It then passes through an orange dye, when the bleached spaces become dyed the primary orange Finally, passage through a series of benzole tanks against revolving brushes removes the printing-ink, and a material is left

stained with alternate green and orange lines, 375 of each to the inch. A second, similar, procedure, with the greasy lines printed at right angles, provides the third primary, blue-violet, and in this way a mosaic of more than half a million blue violet, green, and orange rectangular areas is formed on the surface of the film base.

The colour mosaic is next coated with two protective layers, in order to prevent any desensitising effect of the matrix colours upon the sensitive emulsion. A panchromatic emulsion of very high speed is finally applied. The whole procedure is carried out on 1000-ft lengths of film 21 inches wide, which are slit up into fifteen 'cuts' of standard kinematograph width, 35 mm. A very simple protective device makes it possible to leave a colourless sound track, one-tenth of an inch wide, in each cut, so that the recording of sound with colour can be readily achieved.

Careful control of the coating of the first layer of green collodion has resulted in the production of a matrix of very uniform balance, which has been found indispensable in order that, in the subsequent dyeing processes, a correct balance of spectral distribution is maintained. It is interesting to note that the theoretical primaries have been largely departed from, and that the overlaps in the spectra of the blue, green, and orange regions greatly exceed those usually agreed upon amongst three colour workers. That this has been justified is shown by the extraordinary faithfulness of the colour rendering.

The negative film, after reversal and redevelopment, becomes converted, as already stated, into a positive picture, which can be immediately thrown upon the screen. Such an original or 'master' positive would be of little value were it not possible to make an unlimited number of copies. The copying of any form of geometrical pattern has hitherto involved the appearance in the print of diffraction patterns or moiré, and this has greatly militated against attempts at the commercial application of matrix processes.

Satisfactory duplication of the Spicer Dufay pictures has been effected by a comparatively simple expedient. The coloured original is passed through the gate of the printing machine, and an image of it is thrown by projection upon the copying film, which is synchronously moved forward. The lens has been so designed that it will focus critically the black silver image of the master copy upon the sensitive film of the copying material, while the coloured matrix, which is separated from the image by about 10μ, is slightly blurred or diffused. In this way very exact natural colour copies can be obtained, which are printed at the standard rate of 800 pictures a minute. The ease of duplication at once places the process on a practical basis, for which there will doubtless be many scientific uses, apart from popular entertainment.

Centenary of David Edward Hughes

To commemorate the centenary of the birth of David Edward Hughes, whom Sir Joseph Larmor, in 1900, described as 'one of the great scientific inventors of the age", an address on his life and work was given by Mr Sydney Evershed, on May 14, to the Institution of Electrical Engineers, a society of which Hughes was president in 1886.

Born in London on May 16, 1831, Hughes was the son of a Welsh bootmaker, who in 1838 emigrated to the United States and settled in Virginia. At the age of nineteen he was appointed professor of music in St Joseph's College, Bardstown, Kentucky, and while there gave lectures on natural philosophy. Like many others, he became interested in the rapidly spreading electric telegraphs and in 1854 made a practical type printing telegraph. Resigning his professorship, in 1857 he returned to Europe to exploit his invention.

In the course of the next twenty years, Hughes made a fortune and, taking up his residence in London, devoted himself to scientific research, the first fruits of which was the invention of the microphone. He retained all his life the title of professor and his American citizenship. In 1880 he was elected a fellow of the Royal Society, in 1885 he was awarded a Royal Medal, in 1891 he became a vice president of the Royal Institution, and in 1896, four years after Edison, was awarded the Albert Medal of the Royal Society of Arts. He died from influenza, at his house, 40 Langham Street, on Jan 22, 1900, and was buried in Highgate Cemetery. After his death his widow returned to the United States, where she died about ten years ago. She had given his note books to the British Museum, but much of his apparatus was left in a furniture store near the Tottenham Court Road, where it lay unheeded until 1922. Through the action of the late Mr Campbell Swinton, much of the apparatus was secured for the Science Museum, where it can be seen. Hughes left a fortune of some £470,000. Of this he bequeathed about £13,000 to the Institution of Electrical Engineers, the Royal Society, the Paris Academy of Sciences, and other bodies, but the greater part went to the Middlesex, London, King's College, and Charing Cross Hospitals.

Many of these facts were referred to by Mr Evershed in the course of his interesting address, the main part of which, however, was devoted to a consideration of the two outstanding achievements of Hughes's life, the invention in his early years of the synchronous type printing telegraph, and then, in later life, the discovery of the microphone. "In these his genius was at its height, and, to use an engineering metaphor, it is the peak values that count when we attempt to estimate genius."

In the middle of the last century, said Mr Evershed, electric telegraphy was undergoing rapid development. In England we were using Wheatstone's needle instruments, in America, Morse had produced his ink writer and efforts were being made to make instruments print messages in plain type

At the age of twenty one, and possibly a little earlier, Hughes invented a printing telegraph with features of great ingenuity, devising a method of synchronous working between a revolving arm at the sending end of the line and a revolving type wheel at the receiving end At the receiving end the message was printed on a paper ribbon by the action of an electromagnet in circuit with the line Only one impulse was needed to print a letter

Inventions which come from outside an industry often display originality of thought, and that was true of the Hughes printer But it was something more than original It was what all great inventions are, a complete and practical adaptation of means to an end It worked, and it worked well It deserved to succeed, and it did succeed It was so good that Hughes was not long in getting the invention into use in America, and in 1856 it was adopted by the American Telegraph Company In the land of his birth, however, he discovered he was not a prophet, and so went on to France, where his instrument was widely applied From France he proceeded to Italy, Russia, Turkey, Holland, and other countries, where his ideas were also fully appreciated

With the coming of the submarine cables, Hughes's instruments were installed at the London end of the Continental lines, not on account of the merit of the apparatus, but solely as a concession to foreign idiosyncrasies Yet it is one thing to make a successful invention and quite another to get paid for it Too often the inventor is left to pick up the crumbs from the rich man's table But that was not to be the fate of Hughes He saw to it that he was well paid, and when he returned to England in 1875, from which time onwards London became his home, he was well on the way to making a large fortune out of his printing telegraph

Hughes now entered on the second period of his life, and at the age of forty four, with ample means, he found leisure for the work he loved best, experimental research The opportunity for making a discovery was to come almost immediately

Hughes's first invention was connected with the telegraph his second was connected with the telephone Bell's telephone was exhibited at Philadelphia in 1876, and the world soon realised that the problem of the transmission and reproduction of articulate speech had been solved But the telephone was capable of serving another purpose It was an extremely sensitive detector of minute variation in the strength of electric currents, and so a valuable weapon of research Hughes was one of the first to use the telephone for research, and his experiments led him to the microphone In this direction he was working in an entirely new field with nothing but mother wit to guide him Hughes was no theorist, and by what mental process he stepped from one experiment to the next will never be known Sir Oliver Lodge has said that "Hughes thought with his hands" The truth is that Hughes was born to make experiments and to find his way in the dark

Hughes's experiments are referred to in his paper on "The Action of Sonorous Vibrations on Varying the Force of an Electric Current", read to the Royal Society on May 8, 1878 In this paper he says that, being aware of the effect of light on the electrical resistance of selenium, he had an idea that sound might possibly have a similar effect on electrical conductors Many of his experiments gave negative results, but sounds impinging on the bad contact between the ends of a broken wire were accompanied by sounds in the telephone, and this afforded the clue Carrying on his experiments with loosely touching nails, metallic powders, bits of carbon, and other very simple apparatus, he was in the end able to hear a fly ' walking with a peculiar tramp of his own", and to the simple form of contact, sensitive to sound, he gave the name of microphone'

As soon as Hughes had published his account of the microphone, there followed the usual crop of anticipations But when we have awarded whatever credit attaches to a sporadic disclosure of uncorrelated facts, the honour must go to the man who begins at the beginning and perseveres to the end, the man who feels his way from experiment to experiment, gathering the facts as he goes, and continuing his efforts until the full scope of the inquiry has been brought to light That was the way of Hughes, and when his experiments had disclosed the main body of facts relating to the action of sound on electrical contacts, he gave his knowledge freely to the world

The next thing which engaged Hughes's attention was the induction balance, an ingenious instrument which excited much interest but, contrary to expectation, proved to have a very limited field of utility as a measuring instrument But it led Hughes to other experiments which made him acquainted with strange and bewildering phenomena From the note books preserved in the British Museum, which make interesting but difficult reading, Mr Evershed was able to throw much light on Hughes's experiments on transmitting signals over a considerable distance without conducting wires, which were once witnessed by Spottiswoode, Huxley, Stokes, and others In these experiments, the breaking of the circuit of the primary coil was done under conditions which, as we now know, must have resulted in high frequency oscillations Hughes did not know this, and he was not aware that his extra current was oscillating and that his primary circuit was radiating energy in the form of electromagnetic waves

Hughes, like others, was working at the fringe of a vast field for discovery—the wireless field And even after Clerk Maxwell, in his electromagnetic theory of light, had forged the key to the gate, a good many years went by before Hertz, who knew about Maxwell's theory, took the key and began the work of exploration that led to wireless communication Unfortunately, Hughes was not in possession of the key

In the conclusion of his tribute to Hughes, Mr Evershed remarked "Friendly speech brings

men together as nothing else can, and Graham Bell and David Hughes who gave us the telephone and the microphone deserve to be honoured every day of our lives It would be too much to suggest that you should think of these benefactors of mankind whenever you use the telephone, but the next time you are rung up for some far-distant friend, and hear his well-known voice speaking to you when you lift the telephone to your ear—give a passing thought to Graham Bell And then, when you speak into the mouthpiece of the transmitter—knowing that the microphone inside it will respond and that the current ripples which faithfully represent your voice will be carried far away to your friend—remember what you owe to David Hughes"

Obituary.

The Ven Dr J M Wilson

James Maurice Wilson was born in 1836, was senior wrangler in 1859, an assistant master at Rugby from 1860 to 1879 headmaster of Clifton College from 1879 to 1890, vicar of Rochdale and archdeacon of Manchester from 1890 to 1905, canon of Worcester from 1905 to 1926 The last five years of his life he spent in quiet but not idle retirement near Petersfield, Hants, where he died on April 15

This bare statement does not seem to suggest many opportunities for adventure, yet it was adventure in the very best sense that was the breath of his nostrils It was typical of Wilson that in extreme old age, when death was beckoning to him, he told one nearest to him that, though he did not know what happens to us after death, he was very keen to find out Yes, he was always very keen to find out the truth, and always brave to face it with all its consequences It was not his wont to abide comfortably in the old ways along which habit leads most men to slothful acquiescence Throughout his long life, in action and in thought, he was continually breaking with his past, and gloriously happy in the difficulties that the new work and the new problems presented The changes must have often seemed rash to the onlookers How the wise heads must have shaken when on going up to Cambridge as a classical scholar he turned aside to mathematics, and when as a mathematical master, he allowed himself to be diverted to the teaching of science

Before his Rugby career was over, Wilson contemplated giving up his comfortable house mastership for parochial work, and would have done so had not the headmastership of Clifton been offered him After a few years there, he left his successful work as a headmaster to be a northern archdeacon To many it was a matter of deep regret that no Prime Minister was ever adventurous enough to set him on the bench of bishops The one offer that was made to him was ludicrous It is possible that he might have been an admirable diocesan bishop, it is quite certain that he would have been leaven in the episcopal lump As it was, he had a great influence on religious thought, and must have been a magnet which attracted many to the Church of England and kept many in it The writer of this notice heard his first as well as his last sermon as a schoolmaster Only a few years separated the one from the other Both were instinct with the same buoyant and adventurous but steady faith In all his sermons there was a certain spiritual liveliness, which kept his congregation awake even on a hot Sunday afternoon The events of the day were seized upon to help the understanding and to show the importance of spiritual issues He paid even his youthful congregations the compliment of recognising that they had difficulties in belief, that faith could not be easy to them any more than it had been to him

Stress has been rightly laid on Wilson's ceaseless efforts to harmonise a spiritual faith with the claims of natural science As a young schoolmaster it was his task to assert these latter claims Though the teaching of science had been started in Rugby by Dr Tait in 1849, it was looked upon as an extra, and Wilson taught it as an extra to about fifty boys from all parts of the school, even as late as 1863 Then came the report of the Royal Commission on the nine public schools, including Rugby One of the recommendations of the Commission was that every boy should, at some stage or other of his school career, receive some education in science Dr Temple introduced it at once into the whole middle school, but how could one master and that a mathematical master, cope with the work? A second mathematical master—F E Kitchener—was enticed to co operate with Wilson They insisted on only one subject being taught in all the science classes for the first few terms, so that they might cope with the difficulty What was the subject to be? Temple suggested botany and botany it was, even though neither of the teachers knew the subject Wilson has himself told how the help of Sir J D Hooker, the great curator of Kew, was enlisted He planned out a course of study for the two masters for the summer term They spent the greater part of the summer holidays at Barmouth with a party headed by Prof George Henslow and many enthusiastic collectors and diagram makers, and started teaching botany to 350 boys in September 1864 From that day until Wilson left Rugby he was the inspirer of the science teaching, which was, of course, rapidly extended and no doubt botany was soon elbowed out by its more robust brothers, physics and chemistry It was not only in the work in school that Wilson was an initiator He was one of the founders of the Rugby School Natural History Society, which supplemented in almost ideal fashion the work done more formally It aroused interest in geology, zoology, entomology, and other subjects which were

not taught in the school and yet gave life and unity to the class room work and a common social bond to teachers and to taught

When Wilson went to Clifton, his experience of teaching science and his enthusiasm for it were invaluable He did not himself take a big part in the actual class work, but he collected a band of teachers and gave them the right opportunities Of these they made splendid use Their teaching owed a great deal of its inspiration to the way in which their headmaster encouraged them to do original work Scientific knowledge, the Royal Society itself, would have been poorer had it not been for the opportunities that Clifton gave its masters and its boys during the period of his headmastership

Of Wilson's work at Clifton as a whole there is much to be said Percival had laid solid and noble foundations, Wilson gave the school just the touch of inspiration, intellectual and spiritual, that carried it through the difficult second chapter of its life Men of ability still remember him as a teacher who made Plato a living power in their lives To all, his versatility and enthusiasm meant much He cared little for the solemn pomposities of life, he cared a great deal for the mortal things that touch the human mind When sorrow or shame, success or failure, visited the community—and these are from time to time inevitable visitors in any great school—he never failed in the power to show how he longed to sympathise and restore Now and then, no doubt, he bewildered his subordinates by improvised devices, or by a hurried change of opinion But bewilderment is good for all men, especially for schoolmasters He took a simple and disarming pleasure in his own feats, but was ever the first to proclaim the merits of others Thanks to this generous quality of appreciation, masters of very different and some of very great talents found happy work at Clifton In his northern parish these same qualities shone out for the encouragement of many clergymen and for the spiritual benefit of those laymen who, living among the dark satanic mills, are tempted to cease from mental strife

At Worcester, Wilson mastered a new craft that of deciphering and editing the archives in the Cathedral Library But he did not confine himself to the Library, he spoke his mind in sermons and in lectures on the urgent social problems that affected the city's life, and he imparted his own new-won love of the ancient Cathedral to countless groups of visitors, who followed him spellbound on his courteous and enthusiastic pilgrimages from end to end of the building

It is not fanciful to suppose that in his schooldays Wilson heard the two voices that speak to men of liberty At King William's College the ocean bellowed from his rocky shore, at Sedbergh the mountain floods brought him the same message and all through life he had this music in his ears and rejoiced in it To these voices others deep and vibrant were added as life brought him happiness and sorrow and quickened his imagination So it is for a very rich and venturesome nature that all who knew him are grateful and that all the trumpets surely sounded on the other side W W V

PROF A A MICHELSON, FOR MEM R S

It is just fifty years since Michelson made his first attempt to measure the velocity of the earth through the ether Shortly before his death he was still at work on the same problem The memorable result was in 1887 when, in conjunction with Morley, he performed the famous experiment that ultimately led to the theory of relativity and changed our whole conception of the physical world There was a combination of grandeur and delicacy in the apparatus which strikes the imagination—the massive pier floating in mercury and moving almost imperceptibly in slow revolution, the delicate interferometer capable of detecting a lag of one ten thousand-billionth of a second in the arrival of the light wave, and, as a climax for the theorist, the subtle escape of Nature from the trap that Michelson had set for her

I am not sure that Michelson himself was ever really convinced that this epoch-making work was not a 'failure', for he was disinclined to the new theories But he must have felt the thrill of success when in more recent times his interferometer, now magnified to colossal dimensions, gave the first measurement of the angular diameter of a star His last work reverted to one of his earliest problems, the determination of the velocity of light, I think it is not yet known whether it has realised his most cherished ambition, to determine this constant to within one kilometre per second He stands out as a man who could bring big ideas to fruition

A S EDDINGTON

IN 1899 I chanced to read in the *Journal de Physique* for that year two articles which provided no small part of my interest in life for several years, and the reading of which perhaps determined my career They contained Pellin and Broca's description of the constant deviation prism, and Michelson's of his echelon diffraction grating Michelson's first complete description is in the *Astrophysical Journal* for June 1898

The resolving power of a diffraction grating is proportional to the product of the total number of lines by the order of spectrum observed Consideration of how to increase resolving power by increase of the order of spectrum led Michelson to the idea of replacing the closely ruled reflecting lines of the ruled grating (with its spectra of the first, second, and other small orders) by the reflecting surfaces presented by the steps of a number of glass plates of equal thickness laid on each other *en echelon*, and yielding a spectrum of, say, the 20,000th order He dismissed the idea of a reflection echelon at once as impracticable, saying "The difficulty, even supposing the optical work to be practically perfect, would be the joining of the separate plates in such a way as to have always the same distance between them" But by using the same arrangement for transmission instead of reflection, he avoided these difficulties (though with some sacrifice of resolving power), and the paper describes the use of a transmission instrument to investigate the Zeeman effect

The Michelson echelon came very opportunely for the study of this (the Zeeman) effect announced by Zeeman in 1897, and was very much used during the next ten years for that and for measurements of fine structure by many observers (Galitzin, Koch, Janiki, Nagaoka, Merton, McLennan, and Zeeman himself) Latterly, the quartz Lummer-Gehrcke plate has to some extent supplanted the echelon, chiefly on account of the fact that the lines of greatest interest lie in the ultra violet, which is beyond the range of the transmission instrument Together with the Fabry Perot interferometer, these instruments have contributed in no small degree to the development of modern physics

Quite recently, Michelson's original idea of using the grating as a *reflection* instrument has been successfully realised This is more powerful than the transmission form, and can be used not only for fine structure work in the ultra-violet and Schumann regions, but also for substandard wave length measurements in these regions, to an accuracy very much greater than that hitherto available If the study of hyperfine structure, which is now just developing, fulfils the expectation of contributing to our knowledge of nuclear physics, it would seem that it is to Michelson's reflection echelon that we shall have to look for the greater share of the work F T

WE regret to announce the following deaths

Dr Alwin Berger, an authority on succulent plants and cacti, who contributed a monograph on the Crassulaceæ to Engler Prantl's "Naturliche Pflanzenfamilien", on April 20, aged fifty nine years

Prof J H Comstock, emeritus professor of entomology in Cornell University, and an honorary fellow of the Entomological Society of London, on Mar 20, aged eighty two years

Commander Sir Trevor Dawson, Bart, R N, a past president of the Junior Institution of Engineers and an authority on armaments, on May 19, aged sixty five years

Prof W D Halliburton, F R S, emeritus professor of physiology at King's College, London, and president of Section I (Physiology) of the British Association at the Belfast meeting in 1902, on May 21, aged seventy years

Dr Rudolf Marloth, who was president of the South African Association for the Advancement of Science in 1914 and author of works on the flora of South Africa

Dr Frederick Muir, known for his entomological work especially in the Hawaiian Islands, formerly president of the Hawaiian Entomological Society and vice president of the Entomological Society of London, on May 13, aged fifty nine years

Prof Louis H Pammel professor of botany in the University of Iowa, who was a vice president (Section G) of the American Association in 1919, on Mar 23, aged sixty eight years

News and Views

ON May 20, Lord Rutherford, as chairman of the Advisory Council of the Department of Scientific and Industrial Research, delivered an able and informative speech in the House of Lords on the problem and prospects of obtaining liquid fuel from coal We import, he said, liquid fuel of various kinds to the value of £40 000 000 annually, and failure of this supply would have disastrous consequences to national life So far as can be foreseen, coal is the only possible source of oil in Great Britain Two methods are known for obtaining oil from coal, carbonisation at low or high temperatures, and hydrogenation Lord Rutherford discussed the technical problems associated with low temperature carbonisation and the steps taken by the Fuel Research Board to encourage the development of new retorting systems and to modify and improve low temperature tars, so as to enable them to replace natural products Hydrogenation of tars offers promise of giving good yields of serviceable oils for various purposes, and large scale tests are to be made Much greater yields of oil per ton of coal can be obtained by direct hydrogenation of the coal, which has been shown to be technically possible The development of carbonisation and hydrogenation offer great advantages, but the main problems are economic, for natural oils are available to day in abundance and at very low prices Progress in carbonisation depends on how far the nation is prepared to pay for a purer atmosphere by using cokes instead of coal The hydrogenation process is limited by the degree of willingness of the nation to pay for independence in this matter of liquid fuels Lord Rutherford ended by saying that a full scientific understanding of this problem is more essential to Great Britain than to any other country

LORD PARMOOR, as a Government spokesman, spoke appreciatively of the importance of having in the House men like Lord Rutherford, who are able to deal authoritatively with scientific matters and expound them clearly and adequately to laymen In contrast, on the same day, the House of Commons debated the representation of the universities in Parliament Arguments in favour of ensuring representation of science and scholarship in the House of Commons were resisted in favour of the counting of heads Unfortunately, the case of the universities has been weakened by their own action in selecting members according to their political complexion rather than for their intellectual stature The debate in the House of Lords provides a good argument for the presence of scientific members in the legislature

ON May 24, Prof Einstein, after having had the degree of D Sc conferred upon him by the University of Oxford, delivered at Rhodes House his third and last lecture on the latest developments of the theory of relativity The general theory of relativity, in its original form, was defective, inasmuch as the electromagnetic field was not expressed by means of the metric of the space time continuum as was gravitation A physical basis for such a unified structure was lacking, and one could only be guided by considerations of mathematical simplicity and logical form Prof Einstein's new development depends on a modified form of the Riemann geometry, which admitted distant parallelism (integrability of the law of displacement)

The spatial structure is described by sixteen functions, and the fundamental problem consists in deducing the differential equations of the field for the sixteen vector components Actually, four types of field equations are evolved, of which two contain the old gravitational equations as special cases The other two types may be discarded Of the first two, the one which does not involve Hamilton's principle is the simpler, and Prof Einstein proposes to adopt it He also suggested that the results of quantum mechanics may follow from his new theory, whether his own speculations on the nature of space time are in accord with reality can only be settled by the very difficult integration of the equations

ACCORDING to a dispatch from the Peking correspondent of the *Times*, dated May 24, Sir Aurel Stein has left Kashgar for India, having been compelled to abandon his work in Chinese Turkestan owing to the obstruction of the local authorities He had received permission from the Nanking Government to remain in the province for a period of three years in order to explore the ancient caravan routes It would, therefore, appear that the efforts of the Chinese Society for the Preservation of Ancient Relics to secure his expulsion have been successful It will be remembered that we referred in NATURE of April 11, p 565, to the activities of this body in placing difficulties in the way of expeditions from abroad In spite of the difficulties which beset relations with China, it would be unfortunate if the matter were allowed to rest here It is not a matter which affects archaeologists alone China, as events in the last few years have shown, is becoming increasingly important in several branches of scientific research, and if international co operation has been successful in one science, a *modus vivendi* should be capable of arrangement in other fields Assuming that the Chinese Society for the Preservation of Ancient Relics is not entirely dominated by political motives, and that there is a genuine desire to preserve Chinese antiquities for China, it should be possible to arrive at an international agreement similar to those which have been framed for other countries in which the circumstances are, or were at one time, not dissimilar Such an arrangement would make possible co operation in the scientific development of the country, while preventing its exploitation When a man of science of the standing and reputation of Sir Aurel Stein is prevented from carrying on, in a perfectly legitimate manner, work which is of world wide interest and not merely of local import, the present position is obviously unsatisfactory and calls urgently for action

THE Royal Dublin Society will celebrate its bicentenary during June, as it was founded on June 25, 1731, at a meeting held in the rooms of the Philosophical Society in Trinity College, Dublin The Society at its foundation was known as "The Dublin Society for improving Husbandry, Manufactures, and other useful Arts and Sciences", and during the two centuries of its existence its activities have ranged over all the subjects included in the original title, and have been extended to include pure science, the fine arts, and music They include to day such diverse functions as the Dublin Horse Show, recitals of classical music, and the provision of radon for therapeutic purposes throughout Ireland The bicentenary celebrations will be held at the Society's headquarters at Ball's Bridge, where ample accommodation is available for the large gatherings that a membership roll of nine thousand is likely to entail during the period June 23–27 The functions will include an opening conversazione special scientific and general meetings (the latter on the bicentenary date, Thursday, June 25), a garden party, and a period ball In addition to these functions at Ball's Bridge, their Excellencies the Governor General of the Irish Free State and Mrs McNeill have kindly promised to invite the special guests of the Society to a garden party which will be held in the grounds of the Viceregal Lodge on Wednesday, June 24 An exhibition will be staged in some of the halls and grounds illustrating the advances made in agriculture, industry, science, and art in Ireland during the past two centuries An interesting feature of the bicentenary week will be the presentation to Sir John Purser Griffith of the Society's Boyle Medal, which has recently been conferred on him in recognition of his work in engineering science

Two lecture demonstrations formed a noteworthy feature of the Royal Society conversazione held on May 20 Dr William B Brierley gave a lecture on a kinematograph film illustrating the formation of an intracellular inclusion in a plant cell infected with a virus disease The preparation was made by Dr F M L Sheffield, Rothamsted Experimental Station The film showed a normal cell with its flowing cytoplasm containing the nucleus After infection the protoplasmic streaming becomes more rapid, and numerous small protein particles appear in the cytoplasm which carries them passively around the cell The particles increase in size and fuse, forming a few large aggregations, the motion of which becomes relatively slower, and after a considerable period the inclusions tend to break down, giving a number of protein crystals The second lecturette was given by Mr S R Wycherley, who showed natural colour kinematograph films made by Messrs Spicers, Ltd, of Sawston, Cambridge, the preparation of which is described on p 821 of this issue of NATURE The subjects shown included indoor and outdoor scenes photographed in the studio and out of doors, and also a film of Sir Gowland Hopkins demonstrating biochemical colour tests The tendency in these films is towards a heightening of the colours, particularly of the blue green, but the colour reproduction is, on the whole, very good, and the technical staff of Messrs Spicers, Ltd, are to be congratulated on the results achieved The fact that the films are used in an ordinary kinematograph camera and projector and are non inflammable should ensure their speedy introduction in the kinematograph industry

THE subject of Sir William Bragg's Friday evening discourse at the Royal Institution, on May 22, was "X-Ray Investigation of the Structure of Liquids"

Sir William pointed out that when a pencil of X rays is sent through a liquid behind which a photographic plate is placed, the image when developed shows not only a spot where the pencil has struck, but also in general one or more circular rings surrounding the spot. Of these optical haloes there are at least three kinds. The rainbow may be set down as one of them. Rainbow colours are due to refraction in the spherical drops, and are seen when the observer has his back to the sun. The strangely shaped haloes of the Arctic regions are due to floating crystals of ice. The third kind is represented by the corona so often seen round the moon at night. In the latter case the sizes of the coloured rings depend on the sizes of the drops of water in the cloud or mist. The smaller the ring the larger the drop must be. The result is readily explained on the principle of the interference of light, due to Thomas Young. Particularly good colour effects can be produced in the laboratory by means of artificial fogs. The wave length of the X ray bears approximately the same proportion to the size of the molecule as the wave length of light to the size of the water drop, and some of the rings on the photographic plate can be explained in the same way that the coronæ are explained. But there is undoubtedly more than that in the phenomenon. It appears that sometimes the rings are due to arrangements of the molecules of the liquid in ordered array, as in a crystal, but the arrangements are only fleeting and irregular, so that the sharp pictures obtained with X rays when crystals are used are blurred when the crystal is melted and becomes liquid. It has not been possible, until the X rays provided the means, to demonstrate in a direct manner this tendency to arrangement; it may now be possible to examine its nature and extent in various liquids. It is probably an effective factor in determining liquid properties.

We recently described a successful demonstration of the micro ray system of wireless telephony between Dover and Calais. A new system of telephony called the single side band system was demonstrated on May 21, between the wireless station at Trappes, near Paris, and the station of the Spanish National Telephone Company at Madrid. Both demonstrations were given by the engineers of the International Standard Electric Corporation. The single side band system of telephony was first used some years ago in carrier communication on wire lines. In this connexion, its main advantage is that it doubles the number of speech channels available for the same total band width as compared with ordinary modulation with both side bands. It has also been successfully used on the long wave wireless telephonic circuit between New York and London. Difficulties had to be overcome in applying the side band system to short wave work. During last year, single side band tests were carried out on the radio link between Buenos Aires and Madrid and the one connecting Madrid and Paris. It was found that the received quality was always as good as that obtained when using the double side-band and very definitely better during bad selective and fading conditions. With average fading, the improvement with the new system was at least twice as good as in normal working with both side bands. Rough tests on the improvement of intelligibility showed that it was about four times as high with the single side band system. It appears that a new system applicable to commercial working has been evolved. Mr. A. H. Reeves, the English engineer who devised the new side band system, is to be congratulated. In time, without doubt, his method will be applied to those systems of wireless communication for which narrow limits of synchronisation are essential.

We learn from a *Daily Science News Bulletin*, dated April 2, issued by Science Service, Washington, D.C., that Dr. Bruno Lange, of the Kaiser Wilhelm Institute, Berlin, has invented a new light cell, the sensitivity of which is many times greater than any at present in use. He deposits a thin layer of copper or other metal on the sensitive substance by cathodic sputtering. A wide mesh grid of metal is placed on this. By this means he is able to obtain much larger currents from the copper oxide 'sandwich' for a beam of light of given strength. Siemens and Halske are developing the new photocells, which are stated to have an efficiency at least fifty times greater than those now employed. A small experimental apparatus worked by sunlight has been driving a minute electric motor in dull daylight for some months in Berlin. It is stated that a square yard of copper oxide 'sandwich' can produce several watts of electric power when subjected to full sunlight. The efficiency of this invention will probably have to be improved many hundreds of times before it can be used to provide electric lighting and power on an economic scale. The solar generators will have to be placed in tropical regions where there is little rainfall. Like the alkali photocell, the new invention should find a large number of uses in scientific investigations and in applied science. For sound films and television it should prove very useful. It also makes telephony with infra red rays a possibility. It may lead to devices which will enable ships to signal through fogs, and aeroplanes to determine the position of the sun through thick clouds.

It is known to motorists that up to a certain limit of speed the number of cars that can be accommodated in a given length of street continually increases, but above this limit the number diminishes owing to the greater distance that has to be kept between consecutive cars. This question has recently been investigated by the traffic committee of the American Road Builders' Association. Making average assumptions, they find that at $23\frac{1}{2}$ miles an hour the number of moving vehicles that can pass over a given line drawn across the street per hour is a maximum. Above or below this speed the number of cars that pass the line per hour is less. If the cars have an average length of fourteen feet and travel at only five miles an hour, they need only keep five feet apart, and thus 1380 will pass the line in single file. If they run at ten miles an hour and are fitted with four wheel brakes the distance between them must be increased to eleven feet. In this case 2100 cars cross the line

Proceeding in this way it is found that the maximum number of 2600 cars an hour is attained when the speed is 23½ miles an hour. At a speed of 45 miles an hour only 1760 cars pass the line every hour, which is practically the same as the number that would pass at a speed of seven miles an hour, which with the modern type of car would be an uneconomical speed

THE issue of the first numbers of the *Indian Journal of Agricultural Science* and *Agriculture and Live-stock in India* inaugurates the new series of publications in agricultural and veterinary science issued by the Imperial Council of Agricultural Research, which will take the place of the *Agricultural Journal of India*, the *Journal* of the Central Bureau for Animal Husbandry and Dairying and the Memoirs and Bulletins of the Imperial Department of Agriculture in India The *Indian Journal of Agricultural Science* will be a scientific journal, issued in alternate months, and will largely replace the bulletins and memoirs, and at the same time afford a medium for material which has not been suitably provided for in the past The original articles in the first number include an account of breeding investigations on *Toria*, and papers dealing with the inheritance of characters in Indian linseed and studies in Indian barleys respectively *Agriculture and Live stock in India* is intended to be a general journal appealing to a large circle of readers During 1931 it will appear in alternate months, but it is hoped to issue it monthly in future years The original articles in this first number cover a wide range of interest and include a report on the All Burma tractor trials, a discussion on cattle breeding policy, and papers dealing with various plant diseases In addition, there are in both journals selected articles written by well known authorities on subjects likely to be of special interest and help to those engaged on Indian problems A new feature of these publications will be the abstract sections, whereby it is hoped to keep agricultural research workers in India more fully in touch with other investigators in the country, and permission has been obtained from the newly established Imperial Agricultural Bureaux to reproduce certain of their technical communications and abstracts Attention is directed to the "instructions to authors" contained in these numbers, for only with the co operation of all contributors in the manner prescribed can the Council achieve its aim of prompt publication of scientific work

THAT India has set an example to other parts of the British Empire in forest research is well known So far as research in connexion with tropical forestry is concerned, she has given a lead to the tropical world In some of our colonies and dependencies the Indian example is being followed, and we welcome the first number of the "Record of Forest Research in 1928" of the Nigerian Forest Department (*Bulletin* No 1, 1930) A commencement was made with the inauguration of an Investigation Branch in 1913 This branch started certain investigations into the composition of the growing stock in some of the better known Nigerian forests, and also into the technical and physical qualities of the common timbers The War put an end to these inquiries The first of the new research officers, who are responsible for the present bulletin, are Messrs J D Kennedy and W D Macgregor—both of whom received their forestry training at Edinburgh and, after a few years' work in Nigeria, were given a year's special course, partly at Oxford, on the Continent, and, more important, in India and Burma It was a wise step to send the future research officers to study the progress made in India, for the Indian lines of advance more nearly approach those which many of the forest services of the Empire will follow than the more stereotyped European practices, once these have been correctly assimilated The two officers returned to Nigeria in 1927, and the present report records their work during 1928 Mr Kennedy was stationed at Sapoba, in North Nigeria, and Mr Macgregor at Olokemeji The latter place was at one time the Southern Nigeria Forestry Headquarters Station, and contains much of value and interest The report gives evidence that the lines upon which sylvicultural investigations have been commenced are sound, and some interesting results may be confidently looked for It may be noted that a forest utilisation officer and a wood seasoning officer have also been added to the research staff Whilst much forestry administration and executive work remains to be accomplished in Nigeria, the Department may be congratulated on this important departure in the matter of research

AT the fifty sixth annual general meeting of the Linnean Society of New South Wales, held on Mar 25, Mr E Cheel delivered his presidential address After a review of the Society's activities, he gave a general summary of the myrtle family Upwards of 3000 species are known of the plants commonly called 'myrtles' and these are classified into 74 genera in the family Myrtaceæ The Australian myrtles are widely different from those of other countries, and they form a very important group of the Australian flora on account of the value of their timber, the medicinal and industrial properties of the species, and the utility of the berried fruits The Australian eucalypts play a prominent part in the sylvan culture of millions of acres of land in various parts of the warmer zones of the globe Some eucalypts produce tannin, practically all of the Myrtaceæ are useful bee plants, a number of species of eucalypts has given fairly satisfactory results in tests for wood pulping qualities, *Eucalyptus macrorrhyncha* has yielded a valuable dye-material, myrticolorin Many species of the myrtle family produce timbers suitable for a variety of purposes Forests of these have been exploited, without provision being made for rehabilitation, and re-afforestation is now perhaps the most important forestry problem Different groups of the Australian myrtles yield a variety of essential oils, some of which have a considerable commercial value Following the address, Prof T G B Osborn, professor of botany in the University of Adelaide, was elected president for the ensuing session

CAPT T E JOYCE, leader of the British Museum's expedition of archæological exploration in British

Honduras, returned to London on May 23 This year's expedition, which is the fifth in succession, left England at the end of last January Ten weeks were spent in the bush One of the objects of the expedition was to retrieve the stone stela from Pusilhà, containing the longest and most important of known Maya inscriptions, which had to be abandoned on the return journey last year owing to difficulties of transport and weather Two large plazas on a recently reported site, thirty miles from the coast on South Stann Creek, were explored On the south side of the central dividing mound a collapsed staircase was found, but the buildings were in a bad state owing to the perishable nature of the material, and it was probably owing to the friable nature of the surface afforded by the granite of which they were made that the numerous stelæ showed no signs of inscription On the return journey another site yielded two stone coffins made of slate slabs No bones were found in these Probably they had perished owing to the damp The pottery which had survived was of the consistency of putty owing to this cause Other finds were a finely worked and slender spear head eighteen inches long, an incense burner, jadeite ornaments, greenish stone axes, and a stone knife They are tentatively dated at about A D 500 According to a report in the *Times* of May 25, the objects found will be added to the British Museum, on the understanding that some of them will be returned to Belize should an archæological museum be established in British Honduras

THE Report of the National Physical Laboratory for the year 1930 is a quarto volume of nearly 300 pages, published by the Stationery Office for the Department of Scientific and Industrial Research at 12*s* 6*d* net As in past years, it consists of a general report of the Executive Committee and of more detailed reports from the heads of the various departments The latter give sufficient information as to the methods in use for the solution of the problems in hand, and as to the results which have so far been obtained, to allow the reader to judge for himself the importance of the work being done, whether it is of the scientific or of the industrial type In most cases these reports are provided with illustrations, which add much to their interest So far as the routine tests of instruments and apparatus are concerned, the work for the year does not differ materially in quantity from that of the previous two years, except that many more radium preparations have been examined

VARIOUS government departments continue to call on the National Physical Laboratory for information which involves new experimental work, amongst them the Air Ministry in connexion with the *R101* disaster, and the Home Office with regard to the strength of chains A large proportion of the research on scientific problems is directed by the various research associations which have been formed under the Department of Scientific and Industrial Research or by the Research Committees of the Laboratory During the year, the Laboratory has lost the services of Lord Rutherford and Sir Thomas Stanton by retirement, and of Sir William Smith and Mr Campbell Swinton by death The new physics building and the compressed air tunnel have been completed, and a new ship tank is in course of construction to meet the great demand for tests There is a strong feeling on the part of the Executive Committee of the Laboratory that the demand for work for industry should not be allowed to crowd out research of a more fundamental character which will extend our knowledge and provide a basis for future advances in both pure and applied science

THE March issue of the *Decimal Educator* reproduces the section of the *Chinese Economic Bulletin* for Oct 25, 1930, which deals with the new standards of weights and measures adopted by the National Government on Feb 6, 1929, for the whole of China The ultimate standards are the metre and the kilogram, and, during the transition period, the old weights and measures, which vary considerably throughout China, are to be unified and defined in terms of the metric standards The Sheng is in future to be the Shih Sheng of one litre, the Ch'ih is to be the Shih Ch'ih, one-third of a kilogram The British quart, pound, and yard are stated to have the approximate values, a litre, half a kilogram, and a metre respectively It is noteworthy that these approximate values given in the Chinese document should be those which the Decimal Association in Britain and the Metric Association in the United States advocate for the transition periods in those countries

SIR CHARLES CLOSE, president of the Hampshire Field Club and Archæological Society, recently addressed the Society on "On the Deadliness of Museums", and if his criticisms of the provincial museums of Great Britain were of the obvious and usual type, his suggestions, though not startlingly novel, were based on sound common sense If a provincial or local museum is to be wholly or primarily an instrument of popular education, then the ideal which Sir Charles held up to the curator in his picture of the Neolithic Room was admirably conceived He pointed out that it remains an ideal unachieved as yet in Great Britain, though he finds steps towards it in a few museums, among which, with due regard to his audience, he placed the Cloth Hall at Newbury and the new museum at Basingstoke His final suggestion is that the caretaker (presumably in such a smaller museum) might act as guide, the value of the suggestion depends on the caretaker In general, we believe that the defects of which Sir Charles complains are due not to lack of goodwill or brains in the curators, but to want of means

THE Czechoslovak National Research Council, which is incorporated in the International Research Council, and is an offshoot of the Czech Academy of Sciences, completed the seventh year of its activities at a general meeting held in Prague on Mar 21 Succeeding Prof F L Syllaba, who died on Dec 30, 1930, Prof B Němec was elected president Dr J Bašta delivered a lecture on "The Spirit of Opposition in Scientific Research", in which he emphasised that

the principle of opposition is a fundamental one both in the reactions of matter as well as in the investigator's mind

MESSRS Adam Hilger, Ltd, have issued, under the title of "Spectrum Analysis in Mineralogy", a valuable review by Dr A A Fitch of the technique of mineralogical spectrum analysis and the results that the method has so far yielded The topics dealt with include preliminary treatment of the mineral, optical apparatus, excitation of the spectrum, spectroscopic and spectrographic technique, and methods of qualitative and quantitative analysis of minerals, concentrates, rocks, meteorites, and mineral waters Reference is also made to X ray spectrum analysis of minerals and to mineral determination by means of absorption spectra A long list of examples of the elements found in various minerals by spectroscopic analysis has been compiled, with references to a bibliography of 91 items This alone makes the pamphlet indispensable to all workers in this rapidly advancing field of research Scientific workers will be grateful to Messrs Hilger for providing them with this convenient summary of technical methods and published results, particularly as the latter are scattered through a very wide range of periodicals

THE great advances made in our knowledge of the elements in recent years has led to a desire on the part of many teachers for modern periodic law charts in which this new information has been included Mr John Murray, Albemarle Street, W 1, has just published such a chart, prepared by Mr W H Barrett, of Harrow School, which should meet the requirements of teachers in schools It comprises four separate charts, one of the Periodic Table and Atomic Numbers (after Bohr), one of the Periodic Table and Atomic Weights (after Mendeléeff), one of the Periodicity of Atomic Volumes (after Lothar Meyer), and one of Melting Points and Atomic Numbers It will be seen that these new charts (which together cover an area of 6 ft by 2 ft 2 in) will serve to illustrate the main features of the modern Periodic System, and they will be found most useful in senior courses in chemistry The printing is very clear and the charts are free from unnecessary complications The price of the set, unmounted, is 5s 6d net, or mounted on linen, *9s 6d* The chart is also available mounted on linen, varnished, and on rollers, for the price of *15s 6d* net When the great advantage of such a modern set of charts is kept in mind, these prices must be considered very reasonable The diagrams are sufficiently large to be suitable for classroom teaching, and their use should considerably simplify the teacher's work

AT the annual general meeting of the Institute of Physics, held on May 19, Lord Rutherford was elected president for the year 1931–32

SIR ARTHUR EDDINGTON, Plumian professor of astronomy and experimental philosophy in the University of Cambridge, has been elected a foreign member of the American Philosophical Society, Philadelphia

A LARGE earthquake was recorded at Kew Observatory at 2 hr 27 min 0 sec G M T on May 20 It is estimated that the disturbance originated 1200 miles away, the epicentre being under the Atlantic about 300 miles west of Cape St Vincent

THROUGH the generosity of Lady and Miss Darwin, who have founded a Darwin Trust of about £275 a year, augmented by a contribution from the Medical Research Council, a study of the cause of amentia (feeble mindedness) is to be undertaken at the Royal Eastern Counties Institution for the Mentally Defective at Colchester Dr Lionel Penrose has been appointed research medical officer, and Miss Newlyn social investigator, for this investigation

AT the annual meeting of the Optical Society held on May 14, at the Imperial College of Science and Technology, the following officers were elected for the session 1931–32 *President* Prof A O Rankine, *Hon Treasurer* Major E O Henrici, *Hon Secretaries* W B Coutts (Business), E T Hanson (Papers), *Hon Librarian* Dr J J Hedges, *Editor of Transactions and Assistant Secretary* Dr J J Hedges

PROF ABDUL HAMID BEG, Islamia College, Lahore, sends us a short description of an experiment on the recomposition of white light by the use of a rotating mirror Recomposition by a rotating colour disc is not very satisfactory, as an impure white or grey is seen A better method is to use a lens, or an oscillating mirror, to recombine the colours of the spectrum of white light Prof Beg substitutes for an oscillating mirror a rotating cube having plane mirrors on its vertical sides, and his device may interest some teachers of physics

IN memory of its late editor, Prof Eugenio Rignano, who died on Feb 9, 1930, *Scientia* has founded a Eugenio Rignano Prize of the value of 10,000 Italian lire The prize will be awarded as a result of international competition to the author of the best essay on "The Evolution of the Notion of Time" The works submitted should either be unpublished, or published since 1930, and should be sent for examination not later than Dec 31, 1932 Further information may be obtained from the Editor of *Scientia*, 12, Via A De Togni, Milano (116), Italy

IN a note in NATURE of May 9 (p 714) on the Manchester earth shake of May 3, it was stated, on the authority of the local press, that the shock was not recorded at the Godlee observatory at Manchester We have received a letter from the Rev J P Rowland, *S J*, pointing out that no seismograph has yet been installed at this observatory He also gives a revised estimate for the time of the initial movement recorded at Stonyhurst, namely, 8 h 26 m 0 5 s (G M T), and the time at the origin as 5 seconds earlier The tremors were exceedingly small, the amplitude being not more than 6 7 μ

A USEFUL and well illustrated guide to the larger moths of Eastbourne appears as a supplement to *Trans Eastbourne Nat Hist, Photog and Lit Soc*, vol 10 The author, Mr Robert Adkin, has already

described the butterflies of the district, and this account of the sphingids, bombycids, noctuids, and geometrids forms the second of three instalments

We have received from the Zenith Electric Co, of Willesden Green, London, N W 2, a copy of its latest catalogue of regulating resistances These devices are well known in laboratories, and are now often used in electrical works The latest sliding type of resistance gives very fine adjustment and is cheap As they are flash tested at 2000 volts alternating, they are safe to use in electrical testing rooms

Applications are invited for the following appointments, on or before the dates mentioned —A professor of education in the University of Bristol—The Secretary and Acting Registrar, University, Bristol (June 6) A visiting teacher at the Hackney Technical Institute, for instruction to junior workers in the chemical manufacturing trades—The Education Officer (T 1), County Hall, S E 1 (June 6) An assistant veterinary inspector under the Surrey County Council to carry out duties under the several Acts and Orders relating to milk and dairies, diseases of animals, and such other veterinary duties as the council may require —The Chief Veterinary Officer, County Hall, Kingston-upon Thames (June 8) An assistant marketing officer under the Ministry of Agriculture and Fisheries —The Secretary, Ministry of Agriculture and Fisheries, 10 Whitehall Place, S W 1 (June 8) A full-time teacher of general elementary science and mathematics at the Technical College, Wolverton—The Secretary, Technical College, Wolverton (June 8) A lecturer in physics at the Birmingham Central Technical College —The Principal, Central Technical College, Birmingham (June 12) An assistant lecturer in zoology in the University of Bristol—The Secretary and Acting Registrar, University, Bristol (June 13) A library assistant at the University College of North Wales, Bangor—The Librarian, University College of North Wales, Bangor (June 13) A Thomas Wall reader in comparative education at King's College, London—The Academic Registrar, University of London, S W 7 (June 15) A junior assistant (chemist) under the Department of Scientific and Industrial Research—The Secretary, Department of Scientific and Industrial Research, 16 Old Queen Street, S W 1 (June 16) Keepers of, respectively, ethnology and geology in the Public Museums, Liverpool—The Town Clerk, Municipal Buildings, Dale Street, Liverpool (June 19) A Clothworkers' scholar in the University of Leeds for research in the physical properties of wool and other fibres—The Clerk to the Senate, University, Leeds A graduate assistant master for engineering science and cognate subjects at the Cambridge and County School of Arts, Crafts, and Technology—The Education Secretary, County Hall, Cambridge

Our Astronomical Column.

The Light-Variation of Eros—*Astr Nach* 5784 contains two papers on this subject S Taffara, of Catania Observatory, discusses the period, finding the value 0 109796 day, which agrees exactly with that announced by L Jacchia, of Bologna Most observers take this value as the half period, considering that the complete cycle contains two slightly dissimilar waves The elongation observed at Johannesburg was stated to travel round in the double period 5 h 16 m

The other paper is from Uccle Observatory, by E Delporte and P Bourgeois They determined the magnitude photographically, both by ordinary plates and by plates with a maximum of sensitiveness between wave length 5200 and 5800 With the latter plates a yellow screen was employed, stopping all light of wave length less than 4860 The curves obtained by the two methods are very nearly parallel to each other The distance between them indicates a colour index of 0 77 mag The colour has some influence on the parallax investigation, owing to differential atmospheric refraction One advance in the present parallax campaign over that of 1900–1 is that on this occasion the spectral types of the comparison stars have been determined, so that it will be possible to make allowance for differential refraction, or at least to exclude stars of type differing much from that of Eros

Absolute Magnitudes of *K* type stars—A method was recently devised by Strömberg for determining statistically the distribution of absolute magnitudes in a group of stars The requisite data are proper motions and radial velocities, or derived functions of these quantities, from which accurate values of the frequencies of different absolute magnitudes in the group can be determined Some interesting results have now been obtained by the author in applying his method to *K* type stars (*Astrophysical Journal*, vol 73, p 40) Amongst types *K*0 to *K*2, four distinct maxima appear in the frequency curve at absolute magnitudes −2 5, +0 3, +2 7, and +6 1, the largest number (78 3 per cent) being of absolute magnitude +0 3 It thus appears to be necessary to subdivide the giants into three groups of mean absolute magnitudes equal to the first three maxima, and the designations of bright, normal, and faint giants have been provisionally applied to these groups For stars of types *K*3 to *K*9 only three maxima appear, corresponding to super giants, normal giants, and dwarfs at absolute magnitudes −4 5, −0 1, +6 7 respectively

New Catalogue of Comets—Mr I Yamamoto has just published a new catalogue of comets in the current *Handbook* of Kwasan Observatory Most of the book is in Japanese, but the catalogue is in English It reproduces the orbits given in Galle's "Cometen-Bahnen", with the addition of those that have since been published, extending up to the end of the year 1930, so that it is quite up to date The elements are given to the third decimal of a degree, which is near enough for most purposes There is a useful separate table of the comets of short period, with the approximate date of their next apparition, and a list of the returns at which they were observed There are a few errata Some proper names are misspelt. Skjellerup's comet of 1927 is wrongly identified with De Vico's of 1846 Yamasaki's name is given, instead of that of Forbes, as the discoverer of 1928 IV However, there are probably no catalogues of the kind that are quite free from mistakes The book contains some other tables in English They include elements of satellites and the more interesting minor planets, and a table for converting R A and declination into galactic longitude and latitude.

Research Items.

A Saxon Sword from Wales.—Mr. C. E. Vulliamy describes in *Man* for May the discovery of a bronze ring and sword in a hut circle in the parish of Llowes in Radnorshire. The wall of the hut is marked by a low bank of turf and stones. The interior is filled with sandstone blocks of moderate size, probably fallen from the roof. A lining of massive blocks seems to have served as a revetment of the inside of the walls. A trench across the enclosure from east to west revealed the floor at a depth of eighteen inches to two feet. A small flint knife broken in two pieces and damaged by fire, and two pieces of burnt flint, were found. A surprising find was a small, thick, bronze ring, 1¼ in. in diameter, in debris above the floor in the western sector. This was followed by the discovery of an iron sword, broken in two and thickly covered with yellow rust. It was lying on the collapsed material of the wall. The blade of the sword was badly corroded and the point was missing, but it is undoubtedly Saxon and, it may be assumed, belongs to the pagan period, dating at about A.D. 400-500. The tang and shoulders correspond with datable Saxon swords of about that time. A La Tène date seems improbable, but in the absence of the pommel exact dating is impossible. The length of the sword from tang to point was probably about thirty-four inches. It is interesting to note that the find was made fourteen or fifteen miles from Offa's Dyke and eight or nine miles south of Garth Maelwys, where the Welsh are supposed to have defeated the Mercians in 723. A Saxon dagger and spear ferrule have been recorded from one of the Worlebury hut circles near Weston-super-Mare.

Important Foods of Wild Ducks.—North Dakota is a recognised and favourite resort for wild ducks, and as a consequence is much visited by sportsmen. Its selection by the birds is due to its maze of lakes, sloughs, and ponds, well stocked with suitable food and having plenty of cover. To determine the relative values, and the possibilities of the improvement of the marsh and aquatic areas as feeding grounds for the birds, a survey of the vegetation of about five hundred lakes was made by the late Douglas C. Mabbott and Franklin P. Metcalf in 1917 (*Technical Bull.* No. 221, U.S. Dept. Agric., March 1931). Although the full list of the plants inhabiting the lakes includes the names of about 350 species, the important food-plants for ducks are comprised in some 13 species. Of these, the most abundant is sago pondweed (*Potamogeton pectinatus*), found both in fresh and alkaline saline lakes, and supplying food in the form of abundant underground tubers as well as seeds. Next in importance come wigeon grass (*Ruppia maritima*) and bayonet grass (*Scirpus paludosus*), while the other most useful contributors to the diet include other species of these genera, as well as species of *Sagittaria*, *Lemna*, *Polygonum*, *Ceratophyllum*, and *Chara*. It is noteworthy that almost all the lakes contain at least a small quantity of alkali.

Rabbits and Butterflies.—In a short article in the *Vasculum* (May 1931, p. 68), Prof. Heslop Harrison directs attention to a curious dependence of the numbers of small copper butterflies upon the numbers of rabbits in certain districts. The small coppers depend for food upon the sorrels (*Rumex acetosa* and *R. acetosella*). The latter favours disturbed soils; it is the first invader to appear when whins and heather have been burnt; similarly it is the plant which thrives best among the scrapings and burrows of rabbits. Were the rabbits to disappear in certain places which the author names, the vegetation would close up, sheep's sorrel would disappear, and the small copper would follow suit. It is a series of links in a Nature chain, 'small coppers'—sorrel—rabbits, and Prof. Harrison might have added that we owe our rabbits to the Normans, so that the numbers of 'small coppers' in the British Isles may be said to depend to some extent upon the Norman Conquest!

Japanese Macrura.—Dr. Zu Yokoya describes the Macrura of Mutsu Bay in the "Report of the Biological Survey of Mutsu Bay, 16" (*Science Reports*, Tôhoku Imperial University, 5, 3, 1930. Contribution No. 55 from the Marine Biological Station, Asamushi, Aomori Ken). Thirteen genera and twenty-three species are represented, one genus and four or five species being new. Our knowledge of the geographical distribution is greatly extended, especially of certain southern forms which are now found to live in Mutsu Bay. *Penæus japonicus* is one of these. The new genus *Paraspirontocaris* is closely allied to *Spirontocaris*, but differs in its peculiarly shaped, laterally compressed rostrum projecting obliquely downwards with a rib on each side and small teeth on the upper margin, in the paired carinations of the first and fifth abdominal segments, and in the branchial formula. This new genus is created for the species *Paraspirontocaris Kishinouyei*.

Furunculosis of Salmon.—In two recent papers, a definite advance has been made in the problem of eradication of furunculosis from our salmon and trout fisheries. First, a test has been found whereby *Bacillus salmonicida* can be identified for certain; and secondly, a method for the external disinfection of salmon and trout ova has been successfully tested. Isobel Blake (I. J. F. Williamson) and Eleanor J. M. Anderson (*Fisheries, Scotland, Salmon Fish.*, 1930, No. 1) by the bacteriological test known as the complement fixation reaction have shown that *B. salmonicida* is a serologically homogeneous species. Many strains of other organisms isolated from fish and from fresh water gave consistently negative results. The general test was modified in that the immune serum was heated at 65° C. for half an hour and the complement was treated with charcoal. The first-named author has shown that acriflavine is a suitable agent for disinfecting ova which can carry the furunculosis bacilli (*Fisheries, Scotland, Salmon Fish.*, 1930, No. 2). The bacilli are only present on the outer surface of the eggs and acriflavine in a dilution of 1 in 2000 effectively kills the bacilli without causing injury to the eggs, which should be subjected to the treatment for 20-30 minutes. A method is given for the practical application of acriflavine to eggs at a hatchery on a commercial scale.

New Strains of Welsh Oats.—The Welsh Plant Breeding Station at Aberystwyth is not able to undertake the growing of new varieties of cereals on a large scale so that they may be distributed to meet a general farming demand. The Station is, however, selecting a number of pure lines from some of the commonest Welsh strains and breeding them on sufficiently to enable a comparison of growth habit and yield and behaviour from season to season. It is then prepared to bulk the produce of selected pure lines to an extent sufficient to allow a limited distribution to Welsh growers. If the new line behaves well in ordinary farming practice, then the seed supply may be increased through the farm-grown crop. Two cultivated oat varieties, commonly grown in Wales,

Ceirch Llwyd (*Avena Strigosa*) and Ceirch-du-Bach (*A. sativa*), especially the former, proved to be far from uniform when tested at the Station A number of pure lines were therefore grown from selected heads, and from these, after rigorous elimination, a few have been chosen and grown, as on behaviour and yield they showed better performance than the aggregate The work done in selecting these lines and their characters is described in leaflet S 2 from the Station (1931), by E T Jones Supplies of seed will be available for growers for planting in 1932

Interspecific Plant Hybrids and Backcrosses—The first part of a paper on this subject by E Warren (*Annals* of the Natal Museum, vol 6, part 3) deals with the selfed hybrid generation of *Venidium* and *Arctotis* and the two backcrosses, and a comparison is made of their characters with the corresponding ones in the hybrid and in the two parents In the second part certain aloe hybrids are discussed The hybrids and backcrosses are described in connexion with a statistical treatment of a series of characters, the distributions of the variable in the different generations being given in comparative tables, and by means of certain ratios a comparison, on a numerical basis, is made of the general facies of the different generations of the crosses and backcrosses The daisy hybrid exhibited greater sterility to selfing than to backcrossing, and the plants of the hybrid × hybrid generation were so sterile that no achenes capable of germination were obtained by selfing The aloe hybrids were exceedingly sterile to selfing, and no good seeds were obtained, but backcrossing was comparatively easy This fact is significant in relation to the taxonomy of aloes where hybridisation readily occurs in Nature, and there must be a considerable mixture of species in the population of aloes of many districts where various species are growing together

Ice in the Arctic Sea—The Danish Meteorological Institute has issued its report on "The State of the Ice in the Arctic Seas, 1930" In European Arctic waters there was extraordinarily little ice In the Barents Sea and around Spitsbergen open water was more extensive than in any other year during this century So early as February, the ice edge in the Barents Sea was in the normal position of May and June, and by August it was lying north of the western islands of Franz Josef Land instead of some three degrees to the south Bear Island was free from ice by April, and remained free throughout the summer From the autumn of 1929 until April 1930, the whole west coast of Spitsbergen was clear of ice After a little ice in May and June, the coast was again completely clear, and in July and August, the ice edge lay in lat 81° N During August the entire archipelago was free from ice, and there was practically no ice between Spitsbergen and Franz Josef Land The Kara Sea was clear enough to be navigable in August and September On the east coast of Greenland the ice was fairly abundant until the autumn, when parts of the coast were easily accessible Iceland was almost ice free throughout the year In Davis Strait the amount of ice was below the normal Hudson Strait and Bay were clear of ice in July and August In contrast with these comparatively ice-free coasts, Alaska and eastern Siberia had the pack ice up to their coasts for most of July and August In fact, the polar ice would appear to have been driven against these coasts rather than out into the Barents and Greenland Seas.

X-Rays without Tubes—In the March issue of the *Journal de Physique*, M G Reboul, of the Physics Laboratory, Montpellier, gives an account of the methods which have been developed in that laboratory for the production of X-rays by driving electric currents through solids of high electrical resistivities by high electrical pressures In cases in which a large proportion of the fall of potential occurs in the material either at the anode or at the cathode, that portion of the material is found to emit soft X-rays of the order of 10^{-6} cm, which become harder as the potential fall increases The electrode at which there is a large fall of potential, is given a grid form so as not to interfere with the emission of the radiation The material is used in the form of rods, about 9 cm long and 3 cm diameter, surrounded by ebonite, with an arrangement for pressing the electrodes against the ends of the rod by means of an ebonite screw Magnesia, yellow oxide of mercury, alum, and other materials have been used with differences of potential up to 30,000 volts, and X ray photographs of the usual type obtained

Spectra of Beryllium—A paper by F Paschen and P G Kruger in the *Annalen der Physik* (vol 8, p 1005), on the spectra of beryllium (Be I and Be II), closes an important gap in our knowledge of the properties of the lightest elements These spectra are difficult to produce for technical reasons, and had previously been described only incompletely, but Prof Paschen has now been able to obtain good sources both in arcs and glow discharge tubes The spectra have the structure which would be anticipated, but it is remarkable that a number of lines appear in the spectrum of the neutral atom, which show that two of the electrons can be excited simultaneously, part of the spectrum of the solar corona has been attributed recently to a somewhat similar excitation of helium In this case, it is found that the new lines are most prominent in the presence of some bands which have been tentatively ascribed to the molecule Be_2, and it is suggested that their production is connected with chemical action involving these or other molecules The ionisation potential of the normal beryllium atom is 9 281 volts, and the ionisation potential of its metastable $^3P_2$ state, 6 5675 volts

Phosphorus and Antimony Pentachlorides—Since it is impossible to represent the central atom in the molecules PCl_5 and $SbCl_5$ as surrounded by eight electrons if the five chlorine atoms are attached by ordinary co valent links each corresponding with a pair of electrons, polar formulæ such as $SbCl_4^+Cl^-$, or formulæ in which two of the chlorine atoms are held by single electron links, have been suggested Simons and Jessop, in the April number of the *Journal of the American Chemical Society*, describe experiments on the dielectric properties of these two compounds which show that their molecules possess a zero or very small dipole moment This indicates a symmetrical structure and is in favour of five co valent linkings, with a ten electron shell around the central atom An arrangement with three electron pairs in a plane and two single electron bonds at right angles to this plane is regarded as improbable, since antimony pentachloride is diamagnetic, and it is difficult to see how two unpaired electrons on opposite sides of the central atom could give rise to a mutual neutralisation of magnetic fields An interesting result was that the dielectric constant of liquid phosphorus pentachloride was smaller than that of the solid It is considered possible that the crystal forces distort the molecule and increase the polarisation The liquid has a lower conductivity than the crystalline material This result is interpreted as throwing doubt on the method of finding the polarisation of a substance by making use of the dielectric constant of the solid material

Whipsnade Zoological Park.

THE new estate of the Zoological Society of London at Whipsnade was shown to the Press on May 21. There was a private view for fellows of the Society on the following day, and on Saturday, May 23, it was opened to members of the public, who in future will each day, including Sundays, be admitted on payment of one shilling, from 10 o'clock in the morning until 'lighting up time'.

The Zoological Park, as it is called, considered merely as a place of resort in which to spend some of one's leisure, is most attractive, and from it there is a magnificent view over some eighty miles of country, rivalling that from the Malvern Hills. Much of the five hundred acres consists of downs and woodland, and it is very pleasant to think that so large a rural area is to be kept as a beauty spot.

The charm of the English landscape depends largely upon its vegetation, and the special Act of Parliament, which allows a charge for admission to be made on Sundays, forbids the picking of wildflowers, the damaging of trees and shrubs, and the throwing down of litter. 'Blue bell Wood', where there is no bush undergrowth, is at the time of writing a magnificent sheet of colour, broken only by the trunks of the trees, and there are bluebells too in the Bird Sanctuary, into which the interesting and rare plants of the neighbourhood, which are disappearing elsewhere, will be introduced. Wild birds are protected, and those which build in holes encouraged, by the provision of nesting boxes. No birds other than those usually found in the sanctuaries near London, have as yet been recorded as breeding there. In the enclosure are a few tiny antelopes (Reeves muntjac) and numerous peafowl. The writer here saw several nests of Amherst's pheasant, on which the hens were sitting, and the empty egg shells of an Impeyan pheasant which had successfully hatched out her young. Perhaps the most interesting occupants are the brush turkeys, which it is hoped will build their mounds and leave their eggs to be hatched by the heat of fermentation, as has happened in the Gardens at Regent's Park.

In the disposal of the animals generally, advantage has been very skilfully taken of the conformation of the ground and what is growing upon it. Wolves are rearing their young in a dense wood of conifers, which makes an excellent setting for them. The more scattered trees and bushes make an appropriate home for graceful Indian deer. In a more open space adjacent, and looked down upon from a causeway, is a good collection of bears.

A herd of American bison has been given a large piece of the side of a down, and little dells elsewhere have been fenced round for marmots, wood chucks, and wombats. It is intended to isolate a tableland of grass covered chalk to form a home for lions, and a good beginning has been made with the work. 'Wallaby Wood', consisting of deciduous trees, has as its name implies, been dedicated to the kangaroos. No attempt has been made to provide houses through which the public can walk for any of the animals mentioned, but shelters have been constructed into which the creatures can retire, and which can, if necessary, be warmed in winter by electric radiators.

The orchards, meadows, and the farm-land have been made into grass enclosures for the cranes and crested screamers, the wild horses, asses, and zebras, the camels and llamas, as well as the ostriches, emus, and rheas. The area of several of them is ten acres or more, and there is one of thirty acres, in which it is hoped that there will ultimately be seen a panorama of the large mammals of Africa.

In the Home Paddocks are English 'wild white cattle' of the Chartley strain, and among the herd is a black calf, which points to an occasional crossing in the past with some domesticated breed. There are also red deer, including an albino sport, and, near-by, some lion cubs bred in the Society's Gardens at Regent's Park.

The giving of considerable space to animals, the providing of them with surroundings (and in some cases, food) which approximate to those which they would enjoy in Nature, may be looked upon as mere common sense, seeing that their health should benefit and that they should look better and live longer, for many are costly and difficult, if not, nowadays, almost impossible, to replace. There are, however, other important aspects of the matter. It is allowed that people in Great Britain, at any rate, are gradually becoming more considerate towards animals. Possibly the acceptance of the theory of evolution has helped to create a fellow feeling, and there are now many whose sense of justice is strongly developed who, when they see a wild creature cooped up in a cage or living in a sty unable to roam about and fulfil its functions, cannot help comparing it with a felon imprisoned for life for some crime against society, and consider the animal to be suffering punishment which is undeserved and quite unwarranted.

These, and indeed every lover of animals, will welcome the new Zoological Park as a great advance, for here the animals can be given opportunities to produce their young, and this leads to further business and scientific considerations. Many animals, as has already been mentioned, are of considerable value, and this is especially the case where their export from their native country has been prohibited. The rearing of these and their subsequent sale or exchange may well help to maintain and improve the Zoological Park, for it is intended that any profits from it shall be used for its betterment. Then there are, unfortunately, animals which are dying out, and it may be that the only way to keep them from extinction will be to breed them in captivity.

Visitors to the Park should remember that it is only in its initial stage, and that a great deal of money had to be spent on making roads, although the Ministry of Labour supplied a hundred men from distressed areas and paid three quarters of their wages.

There are at present but few ponds, though considering the accommodation there is a good series of swans and geese and duck, with some flamingoes. It is, however, part of the plan, when funds allow, to make at least one large lake.

The Park should be a great help to the Gardens at Regent's Park. Animals which need a change of food and air can be taken there to recuperate, and any that it is desired to keep but not at the moment to exhibit in London can also be sent into the country. It may not perhaps be too much to expect that those which remain in the Gardens will get a little more room as time goes on.

The moving spirit in the whole scheme has, of course, been Sir Peter Chalmers Mitchell, and he is to be congratulated upon his achievement. This should also gladden the hearts of those whose efforts to improve the conditions at Regent's Park, years ago resulted in his appointment as secretary to the Society. Dr. G. M. Vevers, the Superintendent of the Zoological Gardens, has been staying at Whipsnade for some time, but the resident superintendent is Capt. W. P. Beal.

To follow the boundary of the estate on foot would

mean a walk of eight miles, and the Zoological Society has introduced a service of motor omnibuses of its own, inside the Park The old farmhouse and its out buildings have been made into excellent luncheon and tea rooms, but places have been set apart where visitors may picnic and enjoy the view, while refresh ment kiosks have also been provided

It is understood that motor omnibuses will bring visitors from Luton and Dunstable (which can be reached by train from London) and from the large towns within a convenient distance of the Park

WILFRED MARK WEBB

The Newfoundland Earthquake of Nov 18, 1929

THE Eastern Section of the Seismological Society of America (U S Coast and Geodetic Survey, Washington, D C) has issued two papers, by Dr Arthur Keith and by Messrs E A Hodgson and W W Doxsee, read at the 1930 meeting, at Washington, D C, on the earthquake which broke twelve of the submarine cables to the south of Newfoundland on Nov 18, 1929

The preliminary position of the cable fractures was marked in a map published in NATURE, Dec 21, 1929, and in an accompanying communication Prof J W Gregory explained the earthquake as due to the subsidence of a strip of the sea floor, probably about 400 miles long, in continuation of Cabot Strait This view is fully supported by the new papers The violence of the earthquake may be appreciated from Dr Keith's remark that it was of the same order of magnitude as the disastrous Charlestown earthquake of 1885 He concludes "that all the evidence is in harmony with the theory that parallel faults produced the Cabot trench in the past, the Grand Banks Earth quake in the present, and minor breaks like that of Sherbrooke as aftershocks" He also quotes a report by Thos S Woods attributing the boundary of the continental shelf in that region to faulting

The paper by Messrs Hodgson and Doxsee gives a useful collection of data as to the records of the earth quake, which was felt at all the chief observatories of the world The authors determine the epicentre as at lat 44° 5′ N and long 55° W, and the time there at 20^h 31^m 55^s G M T They conclude that "the evidence strongly supports the hypothesis of a down-dropped section of ocean floor bounded by two fault planes roughly parallel to the axis of Cabot Strait as defined by the 100 fathom contour, and extending from 45° N to about 39° N as a prolongation of that strait, the northern end being the more seriously displaced" The subsidence they suggest was about 25 feet

Messrs Hodgson and Doxsee (p 76) give a list of the times of the earthquake at 32 observatories The time records are of interest in connexion with the view that the floor of the Atlantic is of different material from that under the continents The earthquake records include those at Budapest, 5567 km to the east, and at Berkeley in San Francisco, 5600 km a little south of west Budapest is 33 km nearer the epicentre than Berkeley, it re corded the *P* waves 6 seconds earlier and the *S* waves 7 seconds earlier As the *P* waves travelled to Budapest in 9 min 1 sec and to Berkeley in 9 min 7 sec, the rates of transmission under North America and under the Atlantic were practically equal—the rate to Budapest being 10 29 km per sec, and that to Berkeley 10 24 km per sec The rates were to Munich, distance 5000 km, 9 9 km per sec, to Strasbourg, 4589 km, 9 3 km per sec, to Barcelona, 4700 km, 10 km per sec, and to Balboa, 4506 km, to which the direct route would have been across the deeper part of the North Atlantic basin, only 9 18 km per sec, instead of the acceleration that would be expected if that ocean floor were underlain by sima at a slight depth

University and Educational Intelligence.

CAMBRIDGE —The Appointments Committee of the Faculty of Economics and Politics has appointed C G Clark to be University lecturer in statistics

The Appointments Committee of the Faculty of Biology 'A' has appointed Dr O M B Bulman to be University demonstrator in geology

Mr John Hilton, Assistant Secretary to the Ministry of Labour, has been elected to the recently founded Montague Burton professorship of industrial relations

The Buildings Syndicate has issued a report to the University on a site for the Royal Society Mond Laboratory and on accommodation for the future development of the physical sciences It recommends that the sites of the present engineering workshops and the University power station be assigned for new buildings to contain the Royal Society Mond Labora tory, the reconstructed power station, and new workshops for the Cavendish laboratory, and that the drawing office and adjoining rooms to be vacated by the Department of Engineering be assigned to the Department of Physics

DURHAM —At a meeting of Convocation on May 20, Lord Londonderry was installed as Chancellor of the University, in succession to the late Duke of Northumberland

LONDON —New members of the Senate elected by Convocation include—Major A G Church, M P, and Prof William Wilson (science), in place of Prof F G Donnan and Sir Philip Magnus, who have retired Those reappointed by Convocation and the Faculties include—Sir Ernest Graham Little, M P (medicine), Mr Roger Smith (engineering), and Prof A L Bowley (economics)

Dr C H Lander, since 1923 Director of Fuel Research, has been appointed professor of engineering (Imperial College—City and Guilds College) as from Sept 1, 1931 Dr E L Kennaway, since 1921 chemical pathologist at the Cancer Hospital, has been appointed professor of experimental pathology (Cancer Hospital—Free) as from May 1, 1931

IT is announced by the Cape Town correspondent of the *Times* that, on May 19, the University of Cape Town conferred the honorary degree of D Sc on General Smuts, in recognition of his scientific achieve ments, and with special reference to his election as president of the 1931 meeting of the British Association

THE Rockefeller medical fellowships for the academic year 1931–1932 will shortly be awarded by the Medical Research Council, and applications should be lodged with the Council not later than June 1 Fellowships are awarded by the Council, in accordance with the desire of the Rockefeller Foundation, to graduates who have had some training in research work in the primary sciences of medicine or in clinical medicine or surgery, and are likely to profit by a period of work at a university in the United States before taking up positions for higher teaching or research in the British Isles In special circumstances, the fellowships may be tenable at centres of research not in America. Full particulars are obtainable from the Secretary, Medical Research Council, 38 Old Queen Street, Westminster, S W 1

Birthdays and Research Centres

May 31, 1845 —Col R E CROMPTON, formerly president of the Institution of Electrical Engineers

As I was born in the country eighty-six years ago, in that part of the Vale of Mowbray in Yorkshire where farming is at its best, although I have devoted most of my life to such subjects as mechanical haulage and the supply of electricity to town users and to the greatly increasing industrial districts of England, I have, during the last few years, become more and more impressed by the far greater importance of solving the problem of increasing the food production of our farmlands and gardens, by the use of electrical power We now are all working on the somewhat difficult problem of the distribution of electrical energy at such a low cost that we should be able to persuade our farmers to substitute electrical trenching and aerification of the soil for the old time ploughing and we hope that in the not very distant future we may perfect the processes of obtaining nitrified products, such as nitrate of lime, direct from the nitrogen of the atmosphere, and at points close to where we desire to supply it to our fields, by utilising the electrical supply on the spot, instead of our farmers having to purchase the synthetic products at high cost I, for one, believe it possible that by such means we shall persuade our farmers to increase the area of arable land, and produce from it crops almost, if not quite, equal to those now produced by our market gardeners, largely by manual labour

June 1, 1866 - Dr CHAS B DAVENPORT, director of the Department of Genetics, Carnegie Institution of Washington

Since the study of heredity is really that of the internal control of development, studies on heredity in man, particularly on stature and body build, may usefully be concerned with the way individual children, of known families and races, grow, and especially with the changes in endocrine activity and other physiological factors that are associated with such growth I am, accordingly, following in individual children, during a span of years, their physical, physiological, and mental changes, to learn how they are interrelated

June 2, 1866 —Sir LEONARD E HILL, F R S, honorary director of research at the London Light and Electrical Clinic

Two years ago, working in co operation with Mr R H Davis, of Siebe Gorman, Ltd, I was able to show, with the help of the Admiralty, that it is possible for divers to go to depths of 300 ft in the ordinary living dress The necessary decompression period can be greatly shortened by the breathing of oxygen in a submersible decompression chamber designed by Mr R H Davis, and used from a depth of 70 feet upwards by the ascending diver The chief investigation I have been engaged on is assisting the Admiralty Diving Committee in working out, on animals, safe times for decompression, so using oxygen, for divers working up to thirty minutes on the bottom at 300 ft

I am also engaged in research on the penetration of the skin by infra red, visible and ultra violet rays, and the action of irradiation on the body in health and disease

June 3, 1853 —Sir W M FLINDERS PETRIE, F R S, professor of Egyptology in the University of London

The development of man's abilities and ideas has appeared to me the most interesting subject of research during the last fifty five years At present I am engaged in excavating one of the largest cities of the bronze age and the continuity into the Neolithic period As it is useless to make collections if no place is provided for them, it is to be hoped that the scheme for a study series of development in the great civilisations will be carried out in the new buildings of the University of London

Societies and Academies

LONDON

Royal Anthropological Institute, April 28 —A **Leslie Armstrong** Excavations in the Pin Hole cave, Cresswell, Derbyshire The Pin Hole excavations have been in progress since 1924 By a fortunate circumstance, this cave appears to be the only one of the Cresswell series which held the full story of the occupation of the ravine in Palæolithic times, and it was the only cave left practically intact by earlier excavators Two layers of cave earth exist, an upper level ranging in time from Upper Aurignacian to a phase which is contemporary with the Magdalenian of France This has yielded an important series of tools in flint, which reveal the gradual development of the upper Palæolithic industries of Britain, and also two examples of early art, one of which is the engraved outline, on bone, of a masked male figure The lower cave earth is in three zones, in each of which early Mousterian tools are found and definite evidence of the cave's occupation by man This lower level has also provided valuable evidence relative to fluctuations of climate during the last great ice age of Britain Many animal remains were found

Society of Public Analysts, May 6 —**E J Guild** Demonstration of a new development in filter paper The paper contains at least 99 per cent of alpha cellulose, with about 0 04 per cent of ash It is very strong when wet and offers great resistance to alkaline solution, such as caustic soda, etc It is suitable for the rapid filtration on a large scale of coarse or gelatinous substances, and also for all but the most delicate analytical work —**A J Amos** and **D W Kent-Jones** The 'rope' spore content of flour and its significance Far less importance must be attached to the rope spore content than to the technique adopted in the bakery as a factor in the production of ropy bread The conditions tending to aggravate rope trouble in bread have been separately investigated - **W R Schoeller** and **H W Webb** The separation of tin from tantalum and niobium For the separation of small amounts of tin from much earth acid, Giles's process (fusion with potassium carbonate, solution in citric acid, precipitation of tin as sulphide) is not suitable for earth acid minerals Schoeller and Powell's process (fusion with bisulphate, solution in tartaric acid, treatment with hydrogen sulphide, collection of insoluble residue and sulphide precipitate) is serviceable —**N L Allport** A new method for detecting decomposition products in anæsthetic chloroform The decomposition of medicinal chloroform, resulting in phosgene formation, leads to the presence of free hydrochloric acid due to action on the alcohol which is added as a preservative A new test capable of detecting one part of free hydrochloric acid in a million parts of chloroform is based upon the condensation of resorcinol and vanillin by the free hydrochloric acid, with the formation of a red acidic dye By subsequent treatment with alkali, a pink aqueous layer is obtained, the intensity of the coloration varying with the quantity of impurity present —**J N Rakshit** Contaminations in morphine deposited in the British Pharmacopœia process for

the analysis of opium. The morphine obtained in the determination of the alkaloid by the B.P. process contains 5·6 per cent of other alkaloids consisting principally of codeine. A modified method is described in which a lime solution of the opium is extracted with benzene prior to precipitation with ammonium chloride. This yields a much purer morphine than the original process.

LEEDS

Philosophical and Literary Society, Mar. 3.—**R. Whiddington and J. E. Roberts**: An accurate experimental determination of excitation energy by electron impact in helium. The following values with their probable error in volts were obtained, and a comparison is made with the values calculated from spectroscopic data:

Experimental	Calculated	Origin
21·24 ± 0·03	21·12	$1\,^1S_0 - 2\,^1P_1$
23·19 ± 0·04	22·98	$1\,^1S_0 - 3\,^1P_1$
23·84 ± 0·10	23·63	$1\,^1S_0 - 4\,^1P_1$

The observed values are all a little greater than the calculated ones, but by an amount more than the probable experimental error.—**E. C. Pollard**: Atomic disintegration without capture of the projectile. A discussion of energy and momentum relations is given for a process of atomic disintegration without capture of the alpha particle, and a simple picture of the detailed occurrence is put forward and tentatively considered for the elements aluminium and boron.—**K. E. Grew**: The thermoelectric power of nickel in the neighbourhood of the Curie point. Prior to an investigation of the thermoelectric properties of the copper nickel alloys, the thermoelectric power of nickel (99·97 per cent pure) against platinum at temperatures between 250° and 450° C. has been measured. Preliminary results show that the specific heat of electricity in nickel increases at the Curie point by $4 \cdot 9 \times 10^{-24}$ cal. per electron per degree, in good agreement with the value found by Dorfman and Joanns. Some irregularities in behaviour above the Curie point were observed.—**F. Tyler**: Upper limits for stellar masses—a criticism. The investigations of Anderson and Pokrowski on the upper limit for stellar masses are discussed and criticised.—**H. M. Dawson**: Reaction velocity in relation to the concentration and activity of the reacting components. The best available data for the catalytic influence of hydrochloric acid on the hydrolysis of ethyl acetate show that the velocity is proportional to the concentration of the hydrogen ion and bears no simple relation to its activity or thermodynamic concentration. The rate of conversion of N into p chloroacetanilide in solutions of free hydrochloric acid is consistent with the hypothesis that the velocity is proportional to the product of the activities of the reactants (N chloroacetanilide, hydrogen ion, and chlorine ion), but the results obtained in the presence of chlorides, when the concentration of the chlorine ion is greater than that of the hydrogen ion, show that this hypothesis is not generally applicable. On the other hand, the velocity is in all circumstances approximately proportional to the product of the concentrations of the hydrogen and chlorine ions.—**C. H. Douglas Clark**: A spectroscopic classification of the elements according to ground states. Earlier tables showing the electronic distributions within atoms derived from spectral evidence fail to exhibit the group relationships of the elements, which is especially important from the chemical point of view. A new table is therefore proposed showing the elements (rare earths excepted) in periods and groups, in relation to ground states and corresponding atomic quantum numbers, and also to electronic groups, here divided as ultimate, penultimate, and antepenultimate. The arrangement shows electronic levels in a more compact and convenient form than the schemes hitherto proposed, and forms a suitable basis for discussion of the relation existing between the valencies of the elements and their ground states.—**H. Richmond and W. H. Pearsall**: Absorption of ammonium and nitrate ions by plant tissues. Discs of potato tuber show a higher rate of nitrate absorption in more acid solutions, while ammonium ions are absorbed more rapidly in less acid solutions. Wheat seedlings show a similar type of absorption. *Eriophorum* cuttings, however, absorb more ammonia in acid solutions, and also have a much lower rate of absorption of both ions, in relation to their dry weight.—**W. Garstang**: The phyletic classification of Teleostei. The order Isospondyli is broken up, the Clupeoids being ranged with the Hyodontoids and Ostariophysi in a section termed Otophysi, characterised by a connexion, actual or vestigial, between air bladder and auditory organ, while the Salmonoids are linked with Scopeloids, Salmopercæ, Cyprinodonts, and Synentognathi, which lack all trace of such a connexion. The adipose fin, deeply rooted in the Teleostean constitution, is regarded as a vestige of the second dorsal fin (D^2) of Elasmobranchs and Crossopterygians. Its loss is almost always due to the encroachment of D^1 upon its site, rarely to simple obsolescence. This 'opisthopterous' condition characterises fishes with semi-sedentary (for example, Osteoglossoids) or lurk-and-rush habits (for example, pikes). Accordingly the loss of the adipose fin in Clupeoids indicates the derivation of this group from opisthopterous freshwater ancestors (cf. *Pholidopleurus*), while its presence in Salmonoids indicates an unbroken pedigree of wide roving forms, in which D^1 has preserved its mid-dorsal position throughout (pre-Cretaceous forms still unknown).

PARIS

Academy of Sciences, April 13.—The President announced the death of Raffaello Nasini, *Correspondant* for the Section of Chemistry.—**Léon Guillet, Jean Galibourg, and Michel Samsoen**: The resistance of ordinary steels to high temperatures. Details of measurements with an instrument described in earlier communications. The observations lead to the view that, even for steels at the ordinary temperature, there is not, properly speaking, a true elastic limit, and that the apparent permanence of the dimensions after the application of a small load is the result of the imperfection of the measuring apparatus.—**Auguste Lumière and Maurice Bourgeois**: Blocking the reticulo endothelial system and anaphylactoid shocks. Blocking and shock are two independent phenomena: they may happen together, but there does not appear to be any relation between them.—**W. Slebodzinski**: The symbolic forms of differentials.—**Henri Cartan**: The transformations of limited semi enclosed domains.—**J. Le Roux**: The invariants of the group of relative movements.—**Mlle. Yvonne Dupont**: The invariantive theory of elasticity with finite deformations.—**A. Guillet**: The disruptive state of the plane sphere spark gap in atmospheric air.—**V. Posejpal**: A theoretical formula for the absorption gap.—**Ch. Féry**: A positive electrode with gaseous circulation for batteries with air depolarisation. In the cases where the polarisation is produced by gases lighter than air (hydrogen, ammonia) the positive electrode is hollowed out and the heavier air is led to the bottom of this cavity. The usefulness of this simple arrangement has been proved in practice.—**Pierre Montagne**: The calculation of the equilibria and of the temperature resulting from the combustion of hydrocarbons. The graphical method described in earlier papers has been applied to the combustion of heptane in oxygen

—**André Meyer and Robert Vittenet** The azo derivatives of homophthalimide —**Mlle Eliane Basse** The age of the interstratified basaltic coulées in the Cretacean of the sedimentary border of Madagascar —**Mme M L Le Roux** Parasitic castration and secondary sexual characters in *Gammarus* —**Paul Wintrebert** The determination of the plane of bilateral symmetry in the egg of *Discoglossus pictus* —**Maurice Piettre** The influence of the phenomena of adsorption on the physico chemical properties of organic colloids —**Mme Z Gruzewska, and G Roussel** The amylase of horse serum in the course of numerous successive bleedings Its relations with the serum proteins

GENEVA

Society of Physical and Natural History, Feb 5 —**Léon W Collet** Results of the geological expedition of Harvard University in the Canadian Rockies (Jasper National Park, 1929) (2) The presence of Upper Lias and Bajocian in the Fernie formation of Fiddle Creek Ammonites found by the author, chief of the expedition, and his collaborators show, for the first time, that the Toarcian is represented in the Jurassic formations (Fernie) of the Canadian Rockies The complete Bajocian has also been discovered for the first time in Jasper National Park —**A Amstutz** The existence of palæovolcanic rocks in Sardinia In the course of his researches in Sardinia, the author has produced evidence of eruptions, probably palæovolcanic At the northern base of the mountain of Galtelli, he has, in fact, observed quartziferous porphyries the volcanic origin of which is clearly shown by the fluidity of the mass These rocks of effusion are prior to the Jurassic and are probably contemporary with the large Permocarboniferous eruptions of Corsica —**L Duparc** The fluorspar deposits of Martinèche and Les Isserts near Pontgibaud, Puy de Dôme The author gives a short outline of the deposit, with a hypothetical estimation of the reserves The lodes consist of fluorspar of various colours, colourless, green, and violet —**L Duparc and A Amstutz** The diabases of Mayombé and the adjacent regions (French Congo) The authors have studied the basic rocks, the age of which, relatively to the neighbouring sedimentary formations, is determined by the fact that they penetrate the crystalline schists and more recent metamorphic formations, and that the younger limestone schist series contains pebbles of these rocks They have recognised in it the ophitic, intersertal, and more rarely gabbro structures —**L Duparc and A Amstutz** The enclosure of basic rocks of Moukagni (Gabon) The authors give a brief petrographical description of rocks the dominating character of which is the presence of amphiboles and pyroxenes, enclosed in a black mica granite By analogy with other very numerous cases they consider these rocks as products of metamorphic action of the granite in the calco magnesium sediments of a layer now disappeared —**Ch Cimerman and P Wenger** A micro chemical method for the estimation of glucose in solutions and in urine A modification of Fehling's method, in which the cuprous oxide is removed by the centrifuge instead of by filtration A spot test with guaiacum replaces the ferrocyanide reaction and micro burettes are used for the volume measurements The advantages are no filtration, rapidity, and the use of small quantities of materials and reagents It is possible to estimate very small quantities of sugar in a fluid

VIENNA

Academy of Sciences, Jan 29 —**E Ullrich** Exceptional values of algebroid functions —**E Hofmann** The fruit of *Aspidosperma megalocarpon* and its opening mechanism —**F Seidl, R Enenkel, and H Nohel** Adsorption potential and phase boundary potential of highly resistant glasses —**I Felber-Pisk** The growth of isolated roots Experiments were made in the dark and in the light on the isolated roots of *Phaseolus* —**J Scholz** Atmospheric electricity (73) Theoretical investigations on the distribution of field and ions in a gas which conducts a current and also contains heavy ions

Feb 5 —**F Pauer** Contributions to the preparation of acetals Benzol glycerin (=benz aldehyde-glycerin acetal) and ortho formic acid mono-glycerin ester were prepared Both are colourless, hygroscopic, soluble fluids —**Z Dische, W Fleischmann, and E Trevani** The relation between hibernation and hypoglycæmia The blood sugar contents of active and hibernating animals, for example, of dormice, were determined Insulin was injected, producing in some cases convulsions, but not confirming the idea that hibernation could be produced —**H Schober** The spectrum of rhenium (1) The arc spectrum in the photographic region —**H Popper and O Wozasek** The glycogen content of the diabetic liver

FRIDAY, JUNE 5

ROYAL SOCIETY OF ARTS (Indian Section) at 4 30 —Mrs Patrick Villiers Stuart The Indian Paradise Garden (Sir George Birdwood Memorial Lecture).

PHYSICAL SOCIETY (at Imperial College of Science and Technology), at 5.—Dr H C Hepburn Electro-osmosis and Electrolytic Water transport. Part 2.—J S Badami Spectra of Trebly and Quadruply Ionised Antimony Sb IV and Sb V —G I Finch, R W Sutton, and A E Tooke; *A Time Base for the Cathode-ray Oscillography of Irregularly* Occurring Electric and Magnetic Phenomena.—Dr R. L. Smith Rose and J S McPetrie The Attenuation of Ultra short Radio Waves due to the Resistance of the Earth —Prof S Chapman The Absorption and Dissociative Ionising Effect of Monochromatic Radiation in an Atmosphere on a Rotating Earth Part 2 Grazing Incidence —A Ripple tank Demonstration of Beats as Moving Interference Fringes, by M O Clarke

GEOLOGISTS ASSOCIATION (in Architectural Theatre, University College), at 7 30.—R O Jones The Development of the Tawe Drainage —Dr S W Wooldridge and C J C Ewing Further Observations on the Geology of the Lane End Eocene Outlier

WEST LONDON MEDICO-CHIRURGICAL SOCIETY (at Kensington Town Hall), at 8 15 —Prof J S Huxley *Development in Relation to Heredity* and Evolution (Cavendish Lecture).

ROYAL INSTITUTION OF GREAT BRITAIN, at 9 —Prof E W MacBride Habit—the Driving Force in Evolution

ROYAL SOCIETY OF MEDICINE (Laryngology Section) —Morning and Afternoon

PUBLIC LECTURES.

FRIDAY, MAY 29

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE (Public Health Division), at 5 —N Howard Mummery An Industrial Welfare Scheme

SATURDAY MAY 30

UNIVERSITY COLLEGE, LONDON, at 2 30 —Sir Flinders Petrie The City of the Shepherd Kings (*To be repeated on June 2 at 5 30*)

MONDAY, JUNE 1

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE (Public Health Division), at 5 —Dr F C Shrubsall Mental Deficiency from the Social, Legal, and Educational Aspects.

TUESDAY, JUNE 2

LONDON SCHOOL OF ECONOMICS, at 5 —Prof L. March La methode statistique et ses applications à la Science des affaires (1). (Succeeding Lecture on June 4)

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE (Public Health Division), at 5 —Dr C J Thomas Physically Defective Children (1).

INSTITUTE OF PATHOLOGY AND RESEARCH (St Mary's Hospital W 2), at 5 —Dr A. Gratia The Schwartzman Phenomena.

THURSDAY, JUNE 4

CHELSEA PHYSIC GARDEN, S.W , at 5 —Dr T F Chipp Trees and Man (Chadwick Lecture).

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE (Public Health Division), at 5 —Dr C J Thomas Physically Defective Children (2)

FRIDAY, JUNE 5

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE (Public Health Division), at 5 —R R Hyde Industrial Welfare.

CONGRESSES.

MAY 27 TO 29

CONFERENCE ON MENTAL HEALTH (at Central Hall Westminster)

Friday, May 29, at 5 —The Human Factor in the Social Services
At 8 15 —The Human Factor in Education

MAY 28 TO 30

VEREIN DEUTSCHER CHEMIKER (at Vienna) —Symposium The Separation of Liquids and Solids.

JUNE 1 TO 5

INTERNATIONAL FEDERATION FOR HOUSING AND TOWN PLANNING (at Berlin).—International Housing and Town Planning Congress

JUNE 2 TO 5

INSTITUTION OF GAS ENGINEERS —ANNUAL GENERAL MEETING AND INTERNATIONAL GAS CONGRESS (at Institution of Civil Engineers)

Tuesday, June 2, at 10 A M —Annual General Meeting
Presidential Address.
J S Thorman Intermittent Vertical Chambers and Coal and Coke-handling Plant at Southall
At 2 30 —Dr H Schütte Problems of Modern Gas Distribution
A L Holton The Semi-direct Recovery of Ammonia in Gasworks Practice and the Recovery of Tar Acids from Ammoniacal Liquor

Wednesday, June 3, at 10 A M —C E Paige The Gas Industry in America.

Thursday, June 4 —Dr R. Lessing Clean Coal in the Gas Industry
R. N Webb An Experiment in Controlling Pressure Conditions within Coal Gas Retorts.
At 2 45 —J H Clegg The New Oswald Street Gasworks of the Burnley Corporation

JUNE 3 TO 5

ELECTRICAL ASSOCIATION FOR WOMEN—INTERNATIONAL CONFERENCE (at Glasgow).

Wednesday, June 3, 7 30 to 10.30 P M (at Central Hotel) —Informal Reception

Thursday, June 4, at 10 30 A.M (at Royal Technical College).—Short Papers by representative women, including the following from Overseas —Madame Silfverhielm, Mlle Paulette Bernège, on Electrical Education.

Friday, June 5, at 12 noon (at Royal Technical College) —A. E McColl The Grid in Scotland

SATURDAY, JUNE 6, 1931.

Railway Electrification.*

THE Report of the Committee on Main Line Railway Electrification, of which Lord Weir is chairman, has now been published, and the conclusions reached in it are clear and far-reaching It is satisfactory to find that several of the consulting and railway engineers examined arrived at practically the same numerical results in making estimates

The Report states that electric traction has shown itself to possess definite elements of superiority over steam traction, and that the system is extending wherever it has been adopted

It is pointed out that the progress which is being made by the national scheme for supplying high pressure electricity in bulk and in forming a Central Electricity Board has introduced new factors into the problem of main line electrification The Committee was justified, therefore, in undertaking a comprehensive review of the economic possibility of changing from steam to electricity In making this review, it was assumed that the productivity of the country is ever increasing, and so a transport service must be provided capable of expansion both in method and efficiency The high standard of living adopted in Great Britain has also to be borne in mind

During recent years the revenues of the railways have diminished most seriously, largely due to the growth of road transport for goods and passengers and to the long period of depression in many industries, but nothing has happened as yet to make it at all likely that the railways will be displaced from their position as the chief agency for the transport of goods and passengers in Britain Assuming this, the Committee has attacked the problem and made careful estimates of the extent to which a change from steam to electric traction on our railways would be justifiable and economic

There are many railways abroad operated by electricity and many more are under construction In nearly every case, investigation shows that there are reasons due to special circumstances which induced the country to adopt electric instead of steam haulage, and few of these reasons apply to Great Britain The outstanding example of railway electrification is the Swiss Federal Railway system In Switzerland, 66 per cent of the total mileage is operated electrically and this carries 85 per cent of the total traffic In this case, the main factors governing the choice were the desire to be independent of foreign countries

* Ministry of Transport Report of the Committee on Main Line Railway Electrification, 1931 Pp 57+2 plates (London H M Stationery Office, 1931) 3s net

for supplies of coal and the abundant water power available In addition, there are many steep gradients and long tunnels and these made electric traction almost a necessity It is computed that in 1929 the adoption of electricity effected a saving of £200,000, taking all interest and amortisation charges into account This saving will doubtless increase rapidly as the traffic increases It has to be remembered that in Switzerland the power stations were built by the railway and the interest on their first cost is taken into account in the estimate given above of the saving effected

In France, the main considerations taken into account when electrifying the Paris Orleans railway were the high price of coal south of Paris and the development of the water power sources of central France The linking of this large source of power with Paris is in the interests of national policy It is doubtful whether the railway is yet remunerative The Midi railway electrification utilises available water power, but it obtains a substantial revenue by selling electrical energy to dwellers near the railway and to factories When this latter sum is taken into account, it shows a profit The various electrifications in Germany are due mainly to a desire to utilise available water power There are also many steep gradients and long tunnels which make electrification desirable In Italy and the rest of Europe, similar considerations favour electrification In the United States, there is, in addition, the urgent necessity of increasing the traffic capacity of many of the railways We also see that in some cases the capital cost can be considerably reduced by utilising the 'air space' in large electric stations by building flats and offices above them With steam trains this would be impossible

In Great Britain, the important advantages accruing from the suburban electrification of railways in large towns are now obvious Taking a group of eighteen stations on the Southern Railway within twenty miles from London, it was found that, four years after they were electrified, the number of season tickets issued had increased by 140 per cent It is satisfactory to learn that all electrifications of suburban railways in Great Britain have been uniformly successful The experts calculate that the capital required for the complete suburban electrification of the country, spread over twenty years, would be 45 million pounds The saving effected by electric over steam haulage would be 13 per cent per annum in the twenty-first year There would, of course, be a steam electric period for twenty years But the increased revenue due to electrification would cover the temporary costs of dual working, in addition to paying the interest charges averaged over the whole programme We can assume, therefore, that the railway companies will, in due course, extend the electrification of their lines round London and other large centres The schemes at present in hand strongly support this assumption

The problem of main line electrification in Great Britain needs to be specially considered, as there is little available water power, coal is cheap, tunnels are few, and there are very few appreciable gradients The Committee, therefore, had estimates made by independent experts The major part of the cost of haulage is the cost of the energy expended In steam haulage, this is represented by the cost of the fuel, which in Great Britain is coal In electric haulage the corresponding item is the price paid by the railway for electrical energy The experience gained in only a few other countries is, therefore, applicable The Committee knows that the energy can be purchased from the Central Electricity Board, and it has adopted the overhead direct current system of electrification at 1500 volts as the standard Although the substations will be worked by the railway employees, the cost of their erection and maintenance will be paid by the Central Electricity Board

The essential characteristic of electrification as compared with all other traction systems is the removal of the generation of power from the train From this fact arises most of the advantages and economies of electrification Before a line is electrified, a heavy new interest charge is incurred on fixed equipment, and the independent coal burning locomotives must be replaced by dependent electric haulage units

Estimates made by H W H Richards, J M Kennedy, and Messrs Merz and McLellan indicate that the total capital cost of railway main line electrification in Great Britain would be 261 million pounds, and that the net savings effected would be nearly eighteen million pounds per annum Assuming general electrification on a twenty-year plan, and that existing traffics were maintained, this would lead to a surplus of approximately two per cent after paying the fixed charges on the new capital involved From a business point of view, such a result taken by itself would not warrant the adoption of a scheme of this exceptional magnitude The Committee points out that it has left out of account many things the money value of which cannot be assessed For example, were it completed the railway companies could offer the public

a speedier and much more satisfactory service than they can under steam haulage. Any increase in the service will secure increased savings as compared with steam. It has to be remembered also that British electrical manufacturers have completed many important contracts for railway electrification in many different countries. If the electric scheme is adopted, the experience they have gained would be at once available. With the exception of the raw copper, practically all the expenses would be distributed as wages in Great Britain, and would employ 60,000 men for a period of twenty years. The Committee thinks that notwithstanding the great saving in wage costs effected by electrification, yet there would be little risk of the employees occupying the grades of drivers, firemen and cleaners being adversely affected because of the considerable intensification of suburban services. The physical conditions under which the traction staff would work would be much more favourable than at present.

Apart from its effect on the railways, an electrification scheme on the lines indicated would most favourably affect the National Grid, which is already proving a boon to Great Britain. As to the risk of some more economical method of generating electricity being discovered by science, this discovery would not affect railway economics much, as they would be purchasing electricity and the efficiency of conversion of electrical machinery now approaches a hundred per cent. We have little sympathy with those who oppose the scheme on the ground that new discoveries are continually being made by science. They remind us of the slothful man in Proverbs xxvi. 13, who was continually saying, "There is a lion in the way; a lion is in the streets."

Prehistory

Weltgeschichte der Steinzeit. Von Prof. Oswald Menghin. Pp. xvi + 648. (Wien: Anton Schroll und Co., 1931.) 40 gold marks.

PROF. MENGHIN has taken ten years in the preparation of this extremely important book, and he has certainly not wasted his time. Quite probably it is the last serious work, bearing such an ambitious title, which will ever be written. For it is one of the tragedies resulting from the increase of knowledge, that a general survey of a subject becomes less and less possible. Field workers are, as it were, bricklayers whose position, so close to the small section of wall they are building, makes any general view of the edifice as a whole impossible; and, even for those who are less concerned with the actual building, the structure of knowledge has become so vast and is growing so rapidly as to make a comprehensive study of the whole a very difficult task.

However, Prof. Menghin's book is not only to be welcomed because the Stone Age prehistory of the world is surveyed; quite equally interesting are the new methods of approach to the subject which are here for the first time put forward in print. I say "in print" of set purpose, because in Great Britain several of the same ideas, at least in a modified form, have for some time past been 'in the air', and indeed are already being taught by professional prehistorians. Prof. Menghin, however, has now elaborated and codified these ideas. Briefly, the new schemes depend upon a considerable stressing of the typological method of classification as applied to the Palæolithic and Neolithic cultures as a whole. Prof. Menghin distinguishes, from the earliest times, core, flake, and bone industries, and urges that they are the expression of different modes of life practised by different cultures. The separation of bone using cultures (such as the Maglemosean) is his own special contribution to the new method of approach and one which leads to interesting results—the distinction in Lower Palæolithic times between core—that is, hand axe—(Chelleo-Acheulean) and flake (Clactonian, Levalloisean, etc.) industries has been recognised for some time, also the suggestion made that they belong to different cultures.

Prof. Menghin regards flake industries, such as those already named, as being ancestral to the blade industries such as those of the Upper Palæolithic. Yet surely there is a real distinction between the two, and further, Upper Palæolithic blade industries are associated with burins, forming what can well be described as 'Blade and Burin' industries, a fact which is never the case in Lower Palæolithic flake industries. The difference between a flake and blade is no doubt slight; but it does seem to be a real one. The intriguing suggestion is made that hand axe folk, from the nature of their club-like tools, must have been originally cradled in forest lands, while the dagger and lance points of flake industries postulate a steppe country as the area of origin of the folk who made them. Such generalities are audacious and can sometimes be refuted in detail; but are yet fascinating and often contain important elements of truth.

Another nettle that Prof. Menghin has attempted to grasp is that of Stone Age nomenclature. Quite clearly the world-wide application of terms derived from French place names such as Chellean—there is

scarcely any true Chellean at Chelles—is absurd Moreover, the distinction between the Chellean and the Acheulean cultures is only one of evolution, while between the Acheulean and the Mousterian a much greater gulf exists, a fact which is in no way suggested by the older terminology Again, the classic nomenclature is difficult to apply when the new methods of approach indicated above are adopted Prof Menghin has therefore started *de novo*, but his suggested alternatives are somehow not always happy Nomenclature should be informative, and if possible descriptive, it is true, but need the terms used be in themselves ugly and jaw breaking? "Chwalibogowician" as a name for certain sub-dune Polish industries has been replaced by the name "Swiderian", partly perhaps as a result of slight discord between certain Polish archæologists, but largely because the former word is difficult to spell and impossible to pronounce In Prof Menghin's nomenclature, however, there occur such terms as "Epimiolithic", "Opsimiolithic", 'Epiprotoneolithic", and "Epimixoneolithic"—all quite intelligible if time is taken to think out their implications, and each, in itself, more unattractive than the last Because geologists and petrologists are such sinners in this respect, must prehistorians follow their example? Again, the terms "Protolithic" and "Protoneolithic" are easy to distinguish when written, but can be readily confused in conversation Compare, in this connexion, the trouble that has so often arisen already in the use of the terms Neolithic and Eneolithic

The "Weltgeschichte der Steinzeit", though imposing in contents, is in size and shape convenient enough to handle, and is nicely produced After a brief introduction and a discussion of Stone Age chronology, there is a long chapter on Prof Menghin's first period, the Protolithic This includes everything that has hitherto been classed as Lower Palæolithic and Mousterian The threefold subdivision into core, flake, and bone cultures is explained and adopted, the geographical distribution, evolution, and interaction of each of these groups being considered Incidentally, the author expresses a fairly general scepticism with regard to the Tertiary eoliths Chapter iv contains another detailed account of his next period, the Miolithic, which embraces the Upper Palæolithic and Mesolithic cultures The core, flake, and bone subdivision is continued and elaborated Naturally, the worldwide interactions of these three cultures, now become very complicated as influences from surviving Protolithic predecessors, have to be taken into account and the number of possible combinations and fusions is very great A simple example of such culture crossing is the Solutrean, which is here discussed and analysed It is regarded as the result of a mixture of flake and core culture streams, the one a dagger and lance culture addicted to magic rites and having a tendency to naturalistic art, the other a club-culture with a mother-god cult and a preference for schematic decoration Typically, a Miolithic core culture is the Campignian which it is suggested may have been cradled in Iran Prof Menghin will not tolerate the idea that essentially it is a northern culture The Maglemosean and Arctic cultures are, of course, bone-Miolithic

Next follows a chapter on the Protoneolithic which includes polished axe cultures, as well as those of Anau I and the Gobi Here a somewhat different subdivision is suggested, namely, into cultures specially interested in pigs, cattle, and horses ("Reittierzüchterkulturen") As before, geographical origins, distributions, and interactions are discussed We are thus prepared for a consideration of what is called the Mixoneolithic (= the older 'full Neolithic'), which is divided into village, town, and steppe cultures Finally, there are two chapters dealing with ethnographic linguistic and racial problems in relation to palæo archæology, followed by general conclusions

While perusing this really monumental work, one is constantly impressed—almost appalled—by the amount of material that Prof Menghin has read and absorbed He has also travelled Doubtless many of his details will have to be corrected by field investigators working intensively in various countries, and one feels that he has perhaps dismissed too lightly one or two somewhat thorny problems, but the whole work suggests a new and fascinating approach to the study of prehistory

The typologist is in somewhat the same position as the grammarian He has to systematise a great deal of material and arrange so far as possible that the rules he lays down agree with the facts of reality It has lately been recognised that the current grammar of prehistory is increasingly inadequate —our knowledge of the subject having grown so rapidly in recent years Whether Prof Menghin's new grammar (1) coincides with reality and (2) is sufficiently workable for the purposes of students, the future alone will show While it undoubtedly constitutes a great advance on the earlier schemes, certain factors, such as climate, which tend to produce similar needs and therefore similar industries, are not much stressed or allowed for Moreover, the influence on the final appearance of an industry,

which is exerted by the kind of raw material which is readily available, is a factor which must often be taken into consideration Industries rich in antler-sleeves do not occur when there are no deer There is indeed no need to believe that all somewhat similar industries must necessarily be derived from the same originals For working purposes, the loss of the Mesolithic as a definite stage is perhaps to be regretted Throughout this period, the conditions of life, in Europe at any rate, differed radically from what came before and afterwards Arbitrarily to draw the line at the close of the Mesolithic cultures, and not to make a similar division at the end of the Palæolithic, does not seem to be altogether helpful

But I must reiterate that this is a monumental and remarkable work, which ought to be translated into English It is full of new ideas, and its perusal rather takes one's breath away Prof Menghin is indeed to be congratulated on its production It contains, by the way, plenty of excellent illustrations M C BURKITT

Climate General and Local

(1) *Climate a Treatise on the Principles of Weather and Climate* By W G Kendrew Pp x + 329 + 12 plates (Oxford Clarendon Press, London Oxford University Press, 1930) 15s net

(2) *Die Klimate der Erde* Von Alfred Hettner (Geographische Schriften, Heft 5) Pp iv + 115 (Leipzig und Berlin B G Teubner, 1930) 5 40 gold marks

(3) *Klimakunde von Südamerika* Von Prof Dr K Knoch (*Handbuch der Klimatologie*, herausgegeben von W Koppen und R Geiger, Band 2, Teil G) Pp viii + G349 (Berlin Gebruder Borntraeger, 1930) 67 50 gold marks

THESE three books on climatology, appearing within a short time of each other, meet three different needs The first is for the general reader as well as the teacher, the second is for the teacher and student, and the third for the specialist and librarian

(1) Kendrew's "Climate" is an exceedingly well written and well illustrated general introduction to the subject The distribution of the climatic elements over the globe and the causes of their variation from place to place are described clearly and simply, while the more noteworthy phenomena are illustrated by photographs and quotations in a way which will commend the book to teachers of geography The later chapters, on local details of climate and some typical climatic regions, are also good, and are supplemented by a valuable series of representative weather charts The description of the weather of the temperate storm belts and its basis in the storm-building conflict of 'polar' and 'tropical' winds introduce the modern idea of the 'polar front', which, however, the author does not entirely accept

There are a few slips, for example, "when the path of the sun's rays through the air is doubled the heat received is reduced to a quarter" (p 9), the theory of the deflection of winds by the earth's rotation on p 73 is quite inadequate, and the air temperature need not be above freezing point for the formation of glazed frost (p 213) In Fig 32 we are shown the old diagram of the planetary winds, which Sir Napier Shaw showed to be inaccurate many years ago, and beneath it, an even more impracticable reconstruction of the upper winds It is true that the diagrams are followed by a word of warning, but it is high time that these obsolete illustrations were abandoned altogether by the writers of text books and replaced by something more modern Most of the book is reliable enough, however, while the general get-up, printing, and indexing are all excellently done The volume should find a place on the shelves of all those who are interested in meteorology

(2) Hettner's book, 'Die Klimate der Erde", is a typical German handbook, very complete, very systematic, and very dry Along with solar radiation, atmospheric circulation, water vapour and temperature, it even includes chapters on the chemical composition and dust content of the air and on light and the colour of the sky To cover all this, as well as an outline of the climate of the continents, in a hundred and fifteen pages, requires a very compressed treatment, and while most of the book is clearly written, simplification is sometimes carried too far Thus, the statement on p 16, that the warming of the air depends on its density, ignores the preponderant influence of water vapour, and the reader of the paragraph on the chemical composition of the air will be little wiser for his pains The old fashioned diagrams of the planetary circulation reproduced by Kendrew are also included by Hettner

On the climatic side, the author is much more sound, and his bird's eye view of the climatic provinces is the best part of the book Its value is increased by the numerous clear illustrations, which will appeal to economic geographers and naturalists seeking to correlate their data with meteorology There is no index, but in a work of this nature it is scarcely necessary

(3) The "Klimakunde von Südamerika" falls into quite a different category It is the first instalment of a comprehensive treatise on the climatology of the globe on a scale never before attempted For many years, Hann's famous "Handbuch" has stood as the great work of reference on the subject, with authoritative tables, abundant references, well chosen quotations, and clear discussions of scientific principles But the third edition of the "Handbuch" appeared in 1911, and in the intervening twenty years many more data have been accumulated and much new knowledge gained The task of revision was beyond the powers of any single individual and has accordingly been divided among many The new "Handbuch" will consist of five volumes, one general and four regional, the editors of the whole work are the veteran climatologist, Dr Koppen, and Dr Geiger, of Munich, but each region or continent is assigned to the best authority on its climate The list of authors includes no fewer than thirty five names, most of them known to all meteorologists All the regional volumes are to be on a definite plan, especially the collection of tables, which is regarded as an essential feature of the work, of equal importance with the text

If we may regard Dr Knoch s treatment of South America as representative, the new "Hand buch" will indeed leave little to be desired Beginning with the growth of climatology in the continent, he discusses the geographical factors such as orography and ocean currents, describes the distribution of the climatic elements, and con cludes with detailed climatological accounts of the various countries The treatment throughout is wonderfully thorough, the relegation of most of the tables to the end has permitted a very full development of the descriptive side, partly by quotation and partly in concise summary, with full references to a bibliography of 570 entries There is not a large number of illustrations, but those given are valuable, the distribution of rainfall, for example, is illustrated by no fewer than seven full-page charts The tables occupy eighty pages and include not only monthly normals of all climatic elements, including the frequency of 'phenomena', but also variations of pressure, temperature, and rainfall from normal at selected stations over long periods The figures are reasonably up to date, and the collection of all this material must have been a gigantic task The arrangement, which is by elements, involves much turning over of pages, but, no doubt, arrangement by stations, preferable in theory, would have required too much space

We owe the utmost praise to Gebrüder Borntraeger for their courage in undertaking the publication of a work of this magnitude, no less than to the editors for the broad lines on which it is planned, and, in this beginning at least, to Dr Knoch for the generous way in which the plan has been carried out Few private readers will be in a position to purchase the complete series, but no meteorological, geographical, or reference library can afford to be without it A stout binding should be provided, for the books will be much handled

C E P B

Mathematical Tables and Formulæ

Standard Four Figure Mathematical Tables including many New Tables, Trigonometrical Functions for Radians, Inverse Trigonometrical and Hyperbolic Functions, and an Extended Table of Natural Logarithms By Prof L M Milne-Thomson and Dr L J Comrie Edition B with Negative Characteristics in the Logarithms Pp xvi + 245 (London Macmillan and Co, Ltd, 1931) 10s 6d net

THE object of the authors of this volume of mathematical tables is "to supply a comprehensive set of tables of the numerical values of the elementary functions which are in constant use in mathematics and in the applications of mathematics to physics, chemistry, astronomy, engineering and statistics in those cases where four figure accuracy is sufficient" To attain this object, nineteen tables, occupying 213 pages, are given In each table the authors have endeavoured to supply as complete information as possible of the values of related functions of the same argument, for example, at one opening the computer will find the first five powers, square roots, cube roots, and reciprocals of 100 arguments

A large number of new calculations were made to seven figures and reduced to four figures with the usual convention Many of the tables are claimed to be new, but these are not specified The method of building up these tables and of proof-reading was such that computers may be assured that the accuracy of the tables is high The names of Prof Milne Thomson and Dr Comrie are, in fact, sufficient assurance that the tables have been accurately calculated and printed

For interpolation purposes, first differences are printed where they are useful, and where these become inconveniently large, an alternative method of interpolation is given in some form at the foot

of the page concerned In general, the amount of interpolation required is small For the sake of increased accuracy in working to four decimal places, signs are placed after the tabular results to indicate the possible error involved in the 'cutting down' process A high 'dot', no sign, and a low 'dot' cover a unit of the last figure for this purpose If these signs are used, the results will generally be more accurate

The argument in all the tables has an extensive range and the interval is generally sufficiently small to make interpolation simple Logarithms, antilogarithms, addition and subtraction logarithms are followed by square and cube roots, powers to the fifth and reciprocals of n from 1 00 by steps of 0 01 to 12 00, with additional columns giving square roots of $10n$ and cube roots of $10n$ and $100n$ A table of several functions of the first 100 integers, including logarithm of the factorial and probable error, follows Natural and logarithmic trigonometrical tables for arguments at intervals (i) of 0 01° and 0 1°, (ii) of minutes, (iii) of 0 001 radian, are followed by tables of natural and logarithmic hyperbolic fractions, powers of e, and an extensive table of hyperbolic logarithms Inverse circular and hyperbolic functions, gudermannian and inverse gudermannian, the logarithm of the Gamma function, and the function erf x are the most important of the remaining tables

The main tables are followed by twenty-six pages of derivatives, integrals, series, formulæ, standard differential equations, mensuration, etc This part of the volume will be useful for reference purposes, and a detailed index at the end of the volume would have enhanced its value

An extensive table of proportional parts is provided at the end of the volume and an additional copy can be removed and placed alongside the table in use

The tables are printed very well with the figures of the standard type in modern tables and on very good paper Some of the pages appear rather 'crowded', but not sufficiently so to cause undue fatigue in the user of the tables The book is sold in strong binding

Notation Throughout the volume the logarithm to the base 10 is printed 'log' and the logarithm to the base e is printed 'ln' The choice of notation is not a happy one, for in mathematical text-books 'log' generally signifies the logarithm to the base e This will not be a handicap to the computer when he becomes familiar with it Throughout this edition, negative characteristics are given in the logarithms where necessary, and the writer favours this method of printing the characteristic, a companion edition in which positive characteristics are used is also available

The work of the authors provides an exceedingly useful collection of tables for the large number of computers for whom four-figure accuracy is sufficient

Mammalian Genetics

The Genetics of Domestic Rabbits a Manual for Students of Mammalian Genetics and an Aid to Rabbit Breeders and Fur Farmers By Prof W E Castle Pp vi + 31 + 13 plates (Cambridge, Mass Harvard University Press, London Oxford University Press, 1930) 6s net

AMONG the fanciers and the commercial breeders of the rabbit, there is an increasing number of those who are inclined to agree that a working knowledge of Mendelism is distinctly helpful in the production of new varieties and in the fixation of those which already exist So far, their interests have been served, though imperfectly, by frequent articles in those publications which address themselves to the rabbit keeper, but the need for a small yet comprehensive book on the genetics of the rabbit has during recent years, become manifest Prof W E Castle has written a book which is the first serious attempt to include within one small volume all that is known of the genetics of domestic rabbits, and to indicate how this knowledge may be incorporated profitably into breeding practices

In reading this book, and at the same time continually reminding oneself that the rabbit breeders, of Great Britain at least, are not at all conversant with many of the terms and notions that to the trained geneticist are commonplaces, one is forced to the conclusion that the rabbit breeders of the United States must have a greater knowledge of present day genetics than those in this country The book can thus be of value only to a very few of those who seek and need a simple presentation of fact and theory

To the few, however, the book will prove of very considerable value There is, for example, a chapter entitled "Criteria of True Breeding Types and Individuals", containing a table which shows at a glance the hereditary constitution of the different varieties, and an account of the different mutations that have occurred is placed before the reader in a clear and concise manner No reference is made, however, to the two distinct mutations each of which produces the Rex type of fur, though

this is a matter of considerable importance to the breeder, since it explains how it is that occasionally two Rex rabbits produce normal coated offspring The subject of yellow fat is discussed at some length, but in Great Britain the conclusion of Prof Castle that it is of little or no economic importance is not correct, for many firms pay a considerably lower price for carcases showing this character There are thirty nine photographs of the different types of rabbit, and of these the majority are both clear and helpful The bibliography consists of only about fourteen references

It is impossible to recommend the purchase of this book to the average British rabbit breeder, but to the few who already possess a working knowledge of Mendelism it must prove of very considerable interest The charge is often made that the geneticist finds it impossible to present that which he has to say in terms so simple that anyone may read and understand Many have tried to do this and all have failed It would seem to be far easier to discuss, in everyday language, the origin and nature of the universe than to explain the origin and genetic nature of a new coat colour in the rabbit An understanding of many new words is demanded Is it too much to hope that the breeder, being persuaded that there are financial advantages associated with the possession of a new jargon, will acquire it? The Flora of Northamptonshire Being a Topographical and Historical Account of the Flowering Plants and Ferns found in the County, with short Biographical Notices of the Botanists who have contributed to Northamptonshire Botany during the last Three Centuries By Dr George Claridge Druce Pp cxlii + 304 (Arbroath T Buncle and Co, 1930) n p

THE veteran British botanist, Dr G C Druce, has published a flora of the county in which he was born In many respects the work is a model of what a county flora should be, and must rank with the same author's floras of Oxfordshire, Berkshire, and Buckinghamshire as a noteworthy contribution to the floristics of Great Britain

About 25,000 acres of Northamptonshire are under timber The concise account of the geology (contributed by Mr Beeby Thompson) clearly indicates the dominance of Mesozoic formations of Liassic and Oolitic ages, a fact which explains such peculiarities of the vegetation as the absence of extensive heaths The botanical divisions used by Dr Druce are conveniently based on the river drainage

An interesting feature of the book is an extensive "Botanologia", in which appear biographical accounts of all who have contributed to our knowledge of the botany of Northamptonshire Special attention is directed to those dealing with John Morton, John Hill, and John Clare These biographical notices, and especially the lengthy one on the poet Clare, are of general interest and should prove useful to historians of British botany

The flora of Northamptonshire consists of 977 species (1925 estimate), a somewhat smaller number than estimated for the surrounding counties A list of noteworthy absentees is given The county has no species peculiar to it, but a number of rarities include *Anemone Pulsatilla*, *Epilobium Lamyi*, *Zannichellia gibberosa*, and *Bromus interruptus*

The sequence and nomenclature of species in the systematic part are those of the author's "British Plant List" (second edition) Vernacular names are given and alien species are starred The "grade of citizenship the plant occupies in Northamptonshire", the habitat, the earliest known record for the county, and localities (for all but the common and generally distributed plants) are concisely indicated The listing of microspecies or varieties of *Bursa* (*Capsella*), *Rubus*, *Rosa*, *Cratægus*, *Taraxacum*, and some other genera, makes one wish that critical studies involving cultural and breeding experiments were more in favour with British field botanists

The book is well printed, of convenient format, and the proof-reading has been carefully done

W B T

A Textbook of Plant Physiology By Prof N A Maximov Translated from the Russian Edited by A E Murneek and R B Harvey (McGraw-Hill Publications in the Agricultural and Botanical Sciences) Pp xvi + 381 (New York McGraw-Hill Book Co, Inc, London McGraw-Hill Publishing Co, Ltd, 1930) 20s net

THIS book has been translated into English from the Russian It is a pity that such a step should have proved necessary, for, in view of the relatively large number of universally well known plant physiologists in Great Britain, we should prefer to see such a text book written for our own universities, although it must be granted that it is difficult to conceive of an average syllabus for the subject, at present We have our own familiar books, useful, however, only to the research worker for reference, and too exhaustive to be of any value even to the honours student This probably leads to the state of affairs in the botany schools of British universities, where the student specialises at far too early a stage

Therefore this book should be welcomed if only as a possible means of stabilising the erratic subject It is written by a distinguished physiologist who himself specialises in the water relations of the plant, but he has not allowed such authority to undermine the value of his book by giving it too much prominence The book thus remains a comprehensive though introductory work to the subject of vegetable physiology The first part deals with

the absorption of matter and energy in which photosynthesis, the nitrogen cycle, and other growth factors receive adequate consideration Water relations are examined in the second part from water absorption to transpiration The third part considers the energy question in all its aspects, and growth movement and reproduction take up the fourth part

The whole work is written in an attractive style and is well illustrated All the familiar theories and hypotheses which pervade plant physiology to an inordinate degree are mentioned, but not overworked British, American, and other physiologists are given a fair hearing The excellent and well-balanced choice of material, the masterly way with which it is dealt, and the reference books and periodicals mentioned in an appendix, all make the book a splendid acquisition to plant physiological literature, and one to be recommended to students of the subject up to degree standard

Annual Reports on the Progress of Chemistry for 1930 Issued by the Chemical Society Vol 27 Pp 389 (London The Chemical Society, 1931) 10s 6d net

THE Annual Reports for 1930, issued by the Chemical Society, comprise reviews in the following fields general and physical chemistry (C N Hinshelwood), inorganic chemistry (H Bassett), organic chemistry (aliphatic, E H Farmer, homocyclic, G M Bennett and A W Chapman, heterocyclic, S G P Plant), analytical chemistry (J J Fox and B A Ellis), biochemistry (A C Chibnall and J Pryde), geochemistry (A F Hallimond), radioactivity and subatomic phenomena (A S Russell), and the electrical conductivity of solutions (Sir Harold Hartley, O Gatty, W A Macfarlane, and D M Murray-Rust)

It is customary to endeavour in these reports to present a fairly detailed picture of development in phases of the science, rather than to attempt an annual catalogue of even the more outstanding papers in every branch of pure chemistry They are, in fact, reports rather than summaries, and are in consequence both readable and instructive Thus the first chapter deals *inter alia* at some length with the quantum mechanical treatment of chemical forces, with the elementary processes of chemical change, and with chain reactions, while it intentionally leaves certain equally important matters for more profitable discussion on a future occasion

The reporter on inorganic chemistry protests with justice against the tendency towards multiple publication, whereby the journal literature is distended unnecessarily In the report on analytical chemistry, attention is directed to recent advances in the utilisation of physical methods for analytical purposes, and developments in micro-analysis are mentioned The report on subatomic phenomena and radioactivity reviews work published in 1929 and 1930, most of which has been physical in character. The main object of the report on the electrical conductivity of solutions, which deals chiefly with researches carried out between 1920 and 1930, is to show how far the Debye–Hückel theory is in accord with the results of conductivity measurements A A E

Our Catkin-bearing Plants an Introduction By H Gilbert Carter Pp xii + 61 + 17 plates (Oxford Clarendon Press, London Oxford University Press, 1930) 4s 6d net

THE object of the author in writing this book was to provide a short and concise account of the catkin-bearing trees that could easily be understood by students That he has succeeded in his endeavour is very evident to those who possess an intimate knowledge of the several families to which the term applies Although in the space at his disposal he was unable to deal with all the catkin bearing trees that are hardy in the British Isles, his selection of representatives for each family is such that students should have little difficulty in finding living examples either wild or in parks or gardens In his preface, Mr Gilbert-Carter is very careful to point out the urgent need for students of botany acquiring a knowledge of living plants by studying them as they grow, instead of contenting themselves with the examination of specimens in the classroom, and that advice cannot be too strongly emphasised Mr Gilbert Carter's descriptions of willows, poplars, elms, birches, oaks, walnuts, and other trees are excellent in every way They all appear in easily understood language, and on each page there are explanatory footnotes of the scientific terms used A number of excellent photographs add to the value of the work, which will be found very useful to both teachers and students

About Science a Book for the use of Senior Science Students and those who are going to teach Science By Dr B Millard Griffiths Pp v + 142 (London John Murray, 1931) 3s 6d

DR GRIFFITHS has written a pertinent little book, and one which ought to interest educationists and students alike The unassuming title of the work makes it plain that the author had no intention of giving a complete survey of scientific method, though many of his arguments are framed in an original and persuasive way In his introduction, Dr Griffiths very rightly complains that students of science are told little or nothing about the foundations upon which science stands, because the foundations of knowledge form a part of philosophy, and he maintains, with equal reason, that such an omission is a handicap for them in life, because it makes it difficult for them to appreciate the relationship of science to literature, history, and art, which are important things in life So his book is written mainly for the purpose of interesting science students in the more philosophical aspects of science We wish him success in his attempt But we would go further, and suggest that students would have everything to gain and nothing to lose if their science curricula were less crowded, and if they were given in exchange an introductory course in mental orientation and the methods of knowledge T G

Mouth-Posture Forms of Phœnician Cuneiform Symbols

By the courtesy of M. Virolleaud, the decipherer of the recently discovered Phœnician cuneiform alphabet of Ras Shamra, I have had the opportunity of studying the twenty nine symbols (including alternatives) which he has identified, and the phonetic values which he attributes to them. It is therefore possible to compare the form of the symbols with that of the mouth posture (or gesture) which produced the sound for which it is believed, they each stood. The symbols and their phonetic values and Hebrew equivalents are set out in Fig. 1.

Of the twenty nine symbols, almost every one is suggestive (more or less) of the mouth posture or gesture (for a mouth facing to the left) which produces the sound symbolised. Thus, of the four vowel symbols, that for a (see Fig. 2) represents a flat tongue posture, those for e, é, and i are consistent with progressively higher postures – the middle stroke of the E like symbol being symbolic of the tongue at mid height. Compare the successive cross strokes—corresponding with successive elevations of the tongue posture—in the Ogam vowel symbols, Fig. 2. The comparison of the symbols for é and e with the later symbol E may be noted. There is no symbol for o or u, but the symbol for w is quite suggestive of two protruded lips. Of the symbols for the other bilabial sounds – p, b, m, and ph—p is obviously apposite, b is a double closure, m (two strokes forming a right angle) may symbolise a lip closure, but is not consistent with the p and b symbols. The three primary vertical closures—namely, (voiced) g, tongue to soft palate, d, tongue to hard palate, and b lip to lip—are represented by comparable vertical symbols, of which the bilabial b has monopolised the two stroke symbol.

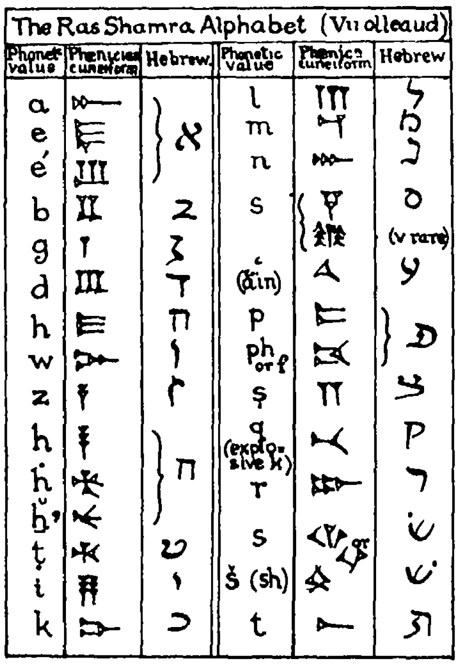

FIG. 1.

The corresponding (so called) unvoiced consonants, k, t, p, though anomalous in that the strokes are horizontal instead of vertical, are consistent with one another. Compare also the triple headed sign for the enduring n with the single head of the momentary t sound. It will be seen that the symbol for n is also closely related to that for d, which is due to a similar tongue posture. The symbol for k may be compared with the funnel shaped symbol for 'ain—both formed by a (more or less) constricted throat. Of the other consonants due to an elevated tongue posture, l is consistent, so are two at least of the different varieties of s (samekh and tsade) and the z sign (zayin). The rare form of samekh may represent the tongue *between* the upper and lower teeth.

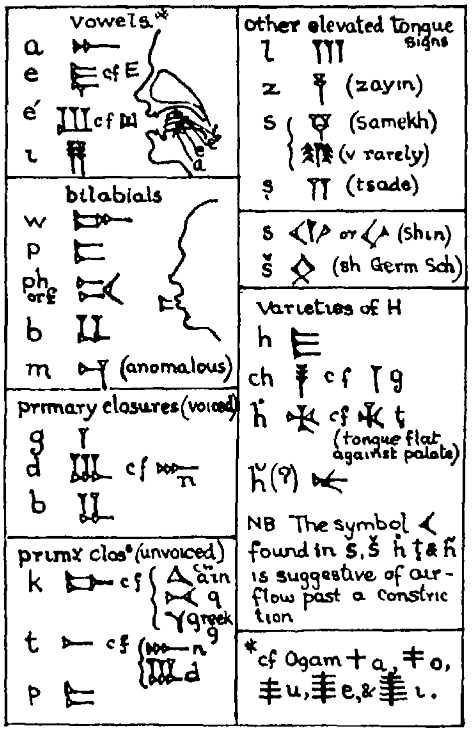

FIG. 2.

There only remain the h sounds, and a ⊰ type of symbol found in the letters h (strongly aspirated in the lower throat), h̆ (?), ṭ (flat tongue against palate), ph or f, q (explosive k), s (shin) and š (German sch), and in the symbol for r. The h symbol (three parallel horizontal strokes) is not inapposite to an air flow through the mouth. The three headed sign for cheth (ch as in German buch) is appropriate for the prolonged sound due to an incomplete g closure—the symbolism of single and triple heads for sudden or prolonged sounds being similar to that already found in t and n, and perhaps also in r. The ⊰ sign seems to represent an air flow through a constriction, since all the symbols which contain it (h, h̆ (?), ṭ, ph, q, s, and š) have this characteristic.

The dawning mouth symbolism which I pointed as appearing in Sumerian cuneiform, in a paper (British Association, Sept. 8, 1930) before the publication of the Ras Shamra alphabet, is substantially confirmed by M. Virolleaud's interpretation of it.

Some examples, taken from that paper, are shown in Fig. 3.

In conclusion, I would emphasise that it is not suggested that the scribe who selected the mouth like cuneiform symbols, whether syllabic or alphabetic, was at all conscious that what he was doing had

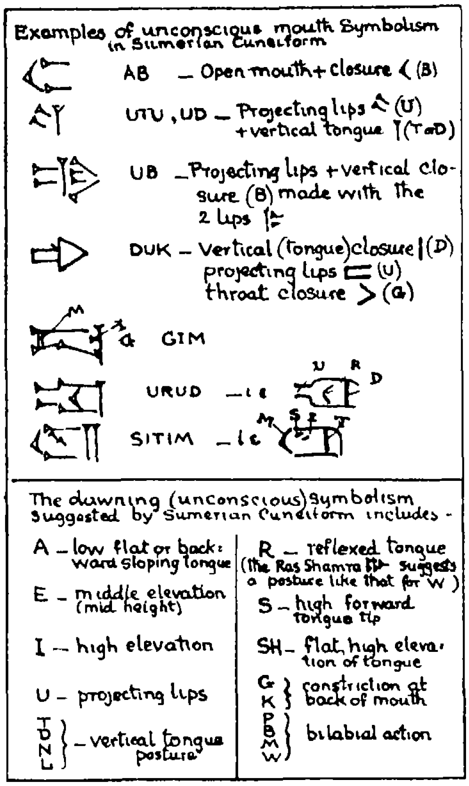

FIG 3

any relation to his own mouth gestures. What I do suggest is that, in choosing a symbol for a given sound he was unconsciously biased in favour of a type of symbol in the making of which his hand followed a track comparable with that which his mouth, tongue, or lips followed in pronouncing the sound of the symbol in question.

Mortality among Plants and its Bearing on Natural Selection

I HAVE followed with considerable interest the recent communications in NATURE of Prof. Salisbury,[14] Prof. Haldane,[1] and Prof. MacBride[2] in connexion with the important matter of mortality among plants and its possible bearing on natural selection.

Prof. Salisbury hopes that other investigators may be induced to record their experiences regarding mortality in young plants, so that it may be possible to judge how general is the phenomenon under consideration. For this reason I refer interested readers to details published by me,[3 13] regarding the mortality in flowers, fruits, young regeneration, and in semi mature, mature, and over mature individuals of certain South African forest species—details based upon investigations carried out during the period 1922-27. Close observation of a systematic nature over a wide area, transect, quadrat, and cultural studies, and instrumental analysis of habitat factors were employed, hence it can be claimed that the data relating to the Knysna forests were collected critically. Furthermore, since 1927 it has been possible to make certain more general observations in subtropical evergreen forest and in savanna vegetation in East Africa; these, while much less critical, in general, support my findings at Knysna.

In the space available I cannot enter into any details, but would refer those interested to the original papers. It is, however, possible to summarise briefly the general nature of the results.

(1) In the species studied—*Podocarpus falcatus* R. Br., *P. latifolius* R. Br., *Olea laurifolia* Lamk., *Platylophus trifoliatus* Don, *Cunonia capensis* L., *Ocotea bullata* E. Mey., *Olinia cymosa* Thunb., *Faurea McNaughtonii* Phill., *Myrsine melanophleos* R. Br., *Apodytes dimidiata* E. Mey., *Gonioma Kamassi* E. Mey., *Virgilia capensis* Lamk.—mortality was found to be greatest in the flowers, fruits, and young regeneration.

(2) Mortality in older stage regeneration, in saplings, poles, large immature and mature trees, in proportion was much less.

Mortality due to insect and fungus ravages was low in all species investigated, except *Olea laurifolia* and *Virgilia capensis*. In *Olea*—a genus taking probably 200-400 years to attain full dimensions, and possessed of a very hard, small pored, heavy timber—mortality due to *Fomes applanatus* (Pers.) Gill, *F. rimosus* Fr., and *Stereum hirsutum* Fr. is high, infected trees being broken above ground by windstorms; in addition, owing to its heavy, large crown and flat root system, this species is wind thrown in large numbers.

In *Virgilia*, the caterpillar of the Silver moth and parasitic *Cassytha* and *Cuscuta* cause premature death in large numbers.

(3) Considering the host of biotic foes and the physical factors working against the production of regeneration in such species as *Olinia cymosa, Platylophus, Cunonia, Ocotea*, and *Faurea McNaughtonii*, it is somewhat remarkable that there is *any* regeneration resulting from *seed*; undoubtedly all these, except *Faurea*, are assisted in holding ground by the fact that they produce abundant, vigorous coppice.

(4) A careful investigation of the principal biological features of sixty three of the more important tree and shrub species of the Knysna,[7] together with the ecological conditions of the communities in which these species grow, shows the following factors to be the prime ones responsible for high mortality:

(i.) Inherent low degree of fertility in flowers and fruits; (ii.) defeat in competition for pollination; (iii.) irregular occurrence of flowering and fruiting seasons (some flower crops produce few or no fruits); (iv.) low capacity of germules for lying dormant—young growth often is produced at uncongenial periods, climatic, edaphic, and biotic; conversely, germules of high dormant capacity are subjected to depredations of various enemies; (v.) unsuitable aerial and edaphic conditions, these acting against efficient germination and establishment; (vi.) insects and fungi attacking flowers, fruits, and (vii.) birds and mammals feeding on flowers, fruits, and seeds, and mammals browsing young regeneration; (viii.) certain strong reactions of *biotic* communities upon habitat factors, principal among these being reactions upon light intensity, soil moisture content, and *water supplying power* of the soil (as measured by Livingstone soil-points).

(5) In the East African savannas, mortality in young stages is due not only to large numbers of termites, rodents, and ungulates, but also largely to seasonal or periodic fires that sweep through great stretches of the country.[12] There is, for example, enormous

mortality in the seedlings of the great genera *Brachystegia* (and *Berlinia*), *Acacia*, *Combretum*, *Terminalia*, and *Commiphora*, while loss in first stage seedling Gramineæ is extremely great in proportion to the numbers produced

(6) Obviously, mortality factors definitely must influence the general distribution of a species—favouring one, hindering another, and through these reactions automatically favouring or hindering yet other species

Any careful student working at the ecology of natural communities should be able to adduce data of similar kind

I have little hesitation in agreeing with Prof Salisbury that the actual selection among the progeny of individuals seems to take place *largely* in those phases of development showing the *least* divergence morphologically—*the young regeneration stages* At the same time, I maintain that we must not lose sight of the mortality rates in the flowering and fruiting phases of older plants this point Prof Salisbury, of course, has taken into account

It might not be without interest to record that, unknown to himself, Prof Salisbury actually was the person who inspired me with a desire to investigate the mortality factors in African vegetation—through the medium of a remark in a letter in 1922 "One is almost accused of having a morbid mind if one emphasises the need for investigation of the factors responsible for mortality in plants"

So much for mortality in plants Observations made by me since 1922 upon various invertebrate and vertebrate groups in *biotic* communities show that among animals the mortality in the young stages is often extremely great From general impressions gained in South and East Africa I feel that a statistical study of the mortality rate in infants and younger children, among primitive peoples, too, would support the view that it is in the earlier stages that there is the greatest proportional mortality, apart, of course, from the actually senile classes JOHN PHILLIPS

Thrips tabaci Lind as a Vector of Plant Virus Disease

Two years ago, there was discovered in a commercial glasshouse in Cardiff a plant of *Solanum capsicastrum* which was affected with a virus disease in which the symptoms consisted of numerous concentric circles on the leaves This virus has been investigated at Cambridge, it has been transmitted by artificial means to various hosts, including the tobacco plant, on which it produces a typical ringspot disease [1]

Further studies have been carried out upon the insect vectors of this ringspot and, out of a number of insects tested, one, *Thrips tabaci* Lind (Morison det) has proved itself a most efficient vector of the virus (Fig 1) This is the first record of plant virus transmission by Thrips in the British Isles

Recently I received from the neighbourhood of Cardiff some tomato plants also affected with a virus Experiments carried out upon these plants showed

FIG 1—A tobacco plant infected with ringspot by *Thrips tabaci* Note the concentric rings, surrounded by a halo, developing close to the feeding marks of the insect, which appear as whitish dots

them to be infected with a very serious virus disease known in Australia as 'spotted wilt' The disease is transmitted in that country by the Thrips, *Frankliniella insularis* Frankl [2] The symptoms of spotted wilt on tomato consist of bronzing of the young leaves,

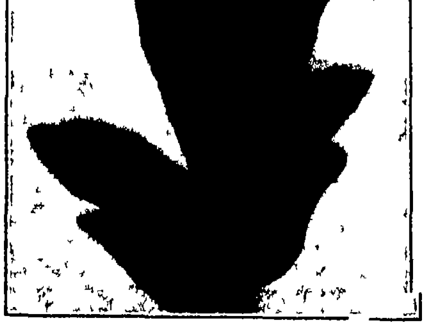

FIG 2—Tomato leaf showing one of the symptoms of spotted wilt, in this case ring like markings on the leaves

the development of ring like markings on leaves and fruit (Fig 2), and cessation of growth—occasionally the plant is killed Experiments at Cambridge have shown that *Thrips tabaci* transmits this virus also

The similarity in the mode of transmission between spotted wilt of tomato and the *S capsicastrum* and

tobacco ringspot, together with certain other factors, suggested the possibility that the two viruses might be the same. A comparative study of the host range and symptom expression on differential hosts of the respective viruses offers almost conclusive evidence that both diseases are due to the same entity. There seems, also, to be little doubt that the dahlia plant acts as another host for the virus. Dahlias affected with a virus disease, which expresses itself in concentric circles on the leaves (Fig 3), occur commonly in the neighbourhood of tomatoes infected with spotted wilt. Inoculation from such dahlias to tobacco and *Datura* produces symptoms indistinguishable from those produced in tobacco and *Datura* by spotted wilt and the *S capsicastrum* ringspot.

FIG 3 —Leaf of dahlia infected with the ringspot virus

The insect vector of tobacco ringspot as it occurs naturally in the tobacco fields of America and elsewhere does not appear to be known. In the light of these new facts, it is worth while to suggest that here also the insect vector may be a species of Thrips, whether there is any connexion between the tobacco ringspot of America and tomato spotted wilt which has recently been discovered there,[3] is still to be proved.

As spotted wilt is a disease of great economic importance in Australia, this announcement of its appearance in the British Isles is of some moment. The Thrips which transmits the virus in England occurs very commonly in glasshouses but, owing to its minute size, is easily overlooked. Its presence can, however, be recognised by the feeding marks of the insect, which consist of silvery white patches on the leaves accompanied by minute granules of excreta. Without in any way wishing to be an alarmist, I would suggest that tomato growers should be on the look-out for the appearance of spotted wilt in their glasshouses.

I have pleasure in acknowledging my indebtedness to Mr John Rees, Adviser in Agricultural Botany, University College, Cardiff, who sent me the affected plants.

The Photosensitised Explosion of Hydrogen-Oxygen Mixtures in the Presence of Chlorine

A RESULT of some interest has recently been obtained relative to the explosion of hydrogen and oxygen by the photosensitising action of chlorine in light from the mercury vapour lamp transmitted by glass. The experiments were initially carried out at a temperature of about 300° C with the view of testing the possibility of the initiation of a hydrogen-oxygen chain mechanism by the hydrogen atoms produced in the hydrogen chloride synthesis. When 280 mm of a mixture ($2H_2 + O_2$) was exposed in a cylindrical glass reaction vessel to light from a mercury lamp, no effect was observed. If chlorine in increasing quantities was added, a sharp limit of chlorine pressure was found, above which a practically instantaneous and quantitatively complete explosion of the hydrogen and oxygen to form water occurred. Below this limit a rapid reaction between the hydrogen and chlorine occurred, which was complete in a few minutes, only a trace of water formation, if any, being observable. The limit of chlorine pressure was exceedingly sharp and could be fixed with precision to one or two mm. In the particular apparatus used it was 135 mm at 300° C. The experiments were then carried out at other temperatures, the quantity of hydrogen oxygen mixture always being adjusted to a constant molar concentration in the reaction bulb. It was found, contrary to initial expectation, that the hydrogen-oxygen explosion could be sensitised down to room temperature, though a much greater chlorine pressure was required at this lower temperature. In the accompanying graph (Fig 1) is plotted the limiting

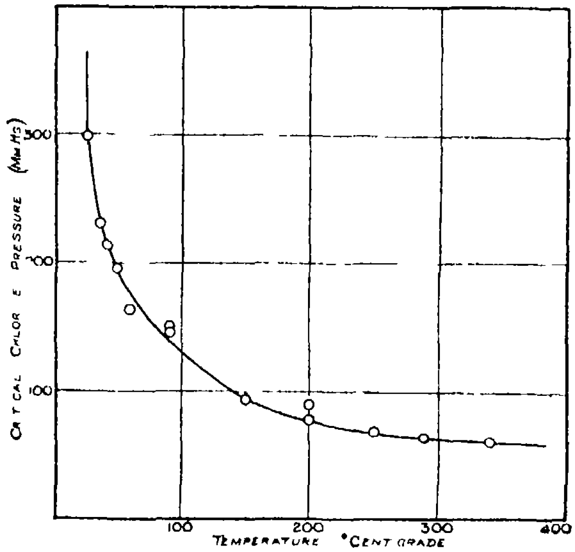

FIG 1

chlorine pressure, reduced to 0° C, required to sensitise the explosion of ($2H_2 + O_2$) at constant molar concentration corresponding to a total pressure of 156 mm at 0° C.

At constant temperature, the limiting chlorine pressure is, roughly, directly proportional to the total pressure of the system, but variation of the hydrogen-oxygen ratio does not markedly affect the limit.

The explosions at the higher temperatures were sharp but not violent, and nearly quantitative. At the lower temperatures they were never complete, and often seemed to partake of the character of a violent detonation.

It is clear that the photosensitising function of the chlorine cannot be solely attributed to the initiation of reaction centres for the hydrogen oxygen reaction. These, in any case, would be incapable of projecting reaction chains at low temperature. More probably its function is twofold. We may suppose that in the first instant of illumination there is a rapid reaction of hydrogen with chlorine, and that some small element of the system is adiabatically raised to the explosion temperature of hydrogen and oxygen. The hydrogen atoms of the hydrogen-chlorine chains then form plentiful starting points for the hydrogen-oxygen chains, and the combination of hydrogen and oxygen spreads out from this point by flame propagation.

This view is borne out by the fact that at a given temperature the explosion always appeared to be connected with a Draper effect (pressure increase), of

limiting magnitude in the mixtures with just less than the critical chlorine pressure Further, while the explosion was more usually apparently instantaneous on admitting the light, there was sometimes a delay of about one second in mixtures close to the limit, when a Draper effect of similar magnitude was observable

A more detailed account of this reaction and a theory of the kinetic mechanism will appear at an early date

Photochemical Interactions of Hydrogen with Chlorine and Bromine

THE photochemical interaction of chlorine and hydrogen has been recently described as an inexhaustible theme Despite the fact that it has been the subject of so many carefully performed experimental researches, it is not yet possible to describe the stages of transformation of the two gaseous elements into the compound hydrogen chloride We have recently solved one of the outstanding difficulties The rate of union of the corresponding reaction between hydrogen and bromine is nearly proportional to the square root of the intensity of the light, that is, to the light absorbed by the bromine in unit time, whereas determinations of the rate of union of chlorine and hydrogen have shown it to be almost directly proportional to the intensity of the light

This marked difference in behaviour we have shown to be due to the fact that the determinations of the rates of reaction with hydrogen and bromine have been made in the absence of impurities which inhibit the reaction, whilst those with hydrogen and chlorine have been made with mixtures which contain such impurities, notably oxygen Our recent experiments show that if the chlorine used in the experiment is separated from the inhibitive impurity, oxygen, by fractional distillation, and then afterwards purified from other inhibitive impurities by washing it with pure water the rate of reaction in question is, like that of the reaction between hydrogen and bromine, no longer directly proportional to the intensity of the light, but more nearly to its square root Moreover, it was shown in this laboratory by E R Boller, almost two years ago, that if a mixture of hydrogen and bromine contains a very small quantity of nitric oxide—an impurity which had previously been shown to be a powerful inhibitor—the rate of formation of hydrogen bromide became proportional to the intensity of the light Therefore, so far as the influence of the light is concerned, these two analogous photochemical changes show the expected correspondence

Optical Activity dependent on Co-ordinated Nickel

IN continuation of our researches on co ordination compounds containing $\alpha\alpha'$-dipyridyl (dipy) we have prepared the following pink complex nickelous salts the chloride $[Ni\ 3dipy]Cl_2,\ 6H_2O$, the corresponding hexahydrated bromide, iodide, and nitrate, and the thiocyanate $[Ni\ 3dipy](CNS)_2,\ 3H_2O$

From the chloride and ammonium *d*-tartrate was obtained a readily soluble dextrorotatory tartrate, $[Ni\ 3dipy]C_4H_4O_6,\ 6H_2O$, which on double decomposition with ammonium chloride furnished an optically active tris $\alpha\alpha'$ dipyridyl nickelous chloride When viewed in the polarimeter illuminated by a mercury arc using the yellow line, a 0 5 per cent aqueous solution of this chloride in a 2 d cm tube gave a maximum rotation of +5 5° which at 20° decreased to +0 08° in one hour The rate of diminution of optical activity between these limits was that required for a unimolecular reaction The maximum activity corresponds with a specific rotation $[\alpha]$ +550° and with a molecular rotation $[M]$ +3877°

Analogous complex salts have been obtained with bivalent manganese and similar cobaltous compounds are under examination

The $\alpha\alpha'$-dipyridyl required for these experiments was obtained by Hein and Retter's method of dehydrogenating pyridine with ferric chloride under pressure, and in this preparation we have so far isolated some ten additional products, including a tripyridyl (tripy) which gives rise to well defined co ordination compounds with bivalent iron and nickel of the general type $[M\ 2tripy]X_2$

Emission Bands in the Mercury Spectrum under Low Excitation

IN a letter published under the above title in NATURE of May 2, it was stated that the series of bands which appear in absorption of the unexcited vapour in the region from λ2943 to λ2614 could be obtained in fluorescent emission by exciting with the iron arc in the region on the long wave side of the resonance line λ2537 It is not necessary to excite close to the resonance line in order to get them This band series accordingly forms part of what I have called the 'wing effect'

A further very definite result is now to be communicated The 'core effect', that is, the fluorescence obtained when stimulation is by the exact wave length of the atomic resonance line as given by a cooled mercury lamp, also includes a band series in the same region of the spectrum, but it is not identical with, or, so far as can be seen at present, definitely related to, the previous band series forming part of the wing effect

It is identical with the series which I formerly measured in electrically stimulated vapour [1] I then called it the emission series of the less refrangible region, to distinguish it from the other series in the same region which had only been obtained in absorption of the unexcited vapour These names are no longer distinctive, and I shall speak for the present, and quite provisionally, of the core series and the wing series, according to the mode of excitation in fluorescence

The wing series is related to the apparently continuous maximum around λ3300 at its tail end by the fact that both are greatly enhanced by superheating the vapour

The core series, on the other hand, seems to be related to the apparently continuous maximum around 2650 at its head, which latter forms part of the core effect, but not of the wing effect Neither the core series nor the maximum 2650 at its head are at all enhanced by superheating

These various relations come out very strongly in the photographs, which it is hoped to reproduce, and which will make them clearer than a short written account can be expected to do

Fine Structure in the Arc Spectra of Bromine and Iodine.

Bromine.—The fine structures of a number of bromine arc lines have been previously reported by Hori [1]. By assuming that the lines λλ6632, 6560, 6351, 6149 have identical structures, De Bruin [2] inferred that the nuclear spin is $\frac{3}{2}$. The fine structure measurements have been considerably extended, using a high frequency (15 megacycles) electrodeless discharge in pure bromine vapour and a Fabry Perot interferometer. All the observed structures arise from the $4p^4 5s$ electron configuration, as was to be expected. Although the lines employed by De Bruin have not identical structures, as he supposed, the value of $i = \frac{3}{2}$ has been confirmed. There is evidence that the two isotopes of bromine (79, 81) have the same nuclear spin.

Iodine.—Fine structures have been previously recorded only in the iodine spark lines,[3] but by employing similar experimental arrangements to those used for bromine, fine structures have been observed in the region λ4700–λ8000. The arc lines are mostly regular quartets and sextets degrading to the violet in both intensity and interval. The simple regularity of the structures is such that they are obviously characteristic of only one j term in each line. The observed structures arise from the $5p^4 6s$ electron configuration, that is, that corresponding to the $4p^4 5s$ in bromine. This is in agreement with the partial analysis of the spectrum made here by S. F. Evans (unpublished). As $2i + 1$ is the maximum multiplicity attainable, the existence of sextet terms proves that i is at least equal to $\frac{5}{2}$, which had been previously inferred from the absence of appreciable alternating intensities in the absorption band lines of I_2.

Since with j less than i the full multiplicity is not attained, the application of the interval rule must decide the value of i (in the absence of Zeeman effect measurements). The best line observed is λ4862, which is a quartet and this involves $j = \frac{3}{2}$ in the $5p^4 6s$ term (this is confirmed by the analysis). The intervals are 123, 103, 83 (cm$^{-1} \times 10^{-3}$), that is, 6×20.5, 5×20.6, 4×20.7. A value of $i = \frac{9}{2}$ must be invoked to fit these exact ratios (6 : 5 : 4), and this value is supported by the interval ratios in other lines.

The most probable values of i for the halogens are shown in the table below.

Halogen	Fluorine	Chlorine	Bromine	Iodine
Number of Protons	19	35 (37 39)	79 81	127
Nuclear Spin	$\frac{1}{2}$	$\frac{5}{2}$	$\frac{3}{2}$	$\frac{9}{2}$

No apparent regularity exists, but the large and small i values are associated with a single isotope. Full details of the fine structure measurements will be published elsewhere.

The Resonance Potential of Trebly Ionised Bismuth

USING the known data of the spectra Hg I,[1] Tl II,[2] and Pb III,[3] and extrapolating by means of the irregular doublet law, the predicted values of the wave numbers of the important combinations $6s6s\ {}^1S_0 - 6s6p\ {}^3P_1$ and $6s6s\ {}^1S_0 - 6s6p\ {}^1P_1$ of Bi IV are approximately 76,000 and 115,000.

In a list of wave-length measurements of the vacuum spark of bismuth in the Schumann region, for which I am indebted to Dr. R. J. Lang, there are very strong lines at 75923 (λ1317.12 A.) and 114601 (λ872.59 A.). If these are assumed to be the above-mentioned combinations, then $6s6p\ {}^3P_1 - 6s6p\ {}^1P_1$ would be 38678. A distinctive feature of the spectra Hg I, Tl II, and Pb III is the appearance with great intensity of lines arising from intercombinations between singlet and triplet terms. One would therefore expect to find the wave number difference 38678 recurring a number of times in the Schumann region. At least five pairs of lines with this difference have been found in approximately the expected positions. However, in spite of this apparent corroboration, I have been somewhat doubtful of the validity of the foregoing identification, because the line 75923 had already been included by Lang[4] in a scheme for Bi III. In a recent paper[5] by McLennan, McLay, and Crawford on the spark spectra of bismuth, the line 75923 finds no place in the scheme for Bi II or for Bi III.

Still more significant evidence that this line belongs to Bi IV, and is in fact the resonance line $6s6s\ {}^1S_0 - 6s6p\ {}^3P_1$, is to be found in the data given by Arvidsson[6] in a recent letter to NATURE, in which it is reported that the line 75923 has been resolved into three components of relative intensities 6 : 5 : 5. If it is assumed that the nuclear quantum number of bismuth is 9/2 and that the $6s6s\ {}^1S_0$ term is single, then the theoretical relative intensities of the three components of the $6s6s\ {}^1S_0 - 6s6p\ {}^3P_1$ combination as calculated by the formulæ given by Pauling and Goudsmit[7] is 6 : 5 : 4 in order of decreasing wave number. This agrees very closely with the experimental ratio. It therefore seems very probable that this is the resonance line of Bi IV, giving the value 9.36 volts for the resonance potential.

Some progress has been made in finding further wave number regularities in Bi IV, but the spectrum is difficult to interpret because of the j, j coupling of the two electrons. The work is still proceeding and it is hoped that a detailed report will be made elsewhere at a later date.

Impact Figures on Polished Rock Salt Surfaces

IF a small steel ball is dropped from a height of a few inches on a polished rock salt surface, the imprint of the ball on the crystal surface remains as a circular depression of one or two millimetres in diameter. The surface is deformed, however, over a region many times the area of the circular depression. If an optical test plane (a piece of ordinary plate glass will do) is placed on the crystal and the surface examined in monochromatic light, the interference pattern shows a number of families of 'loops' extending away from the imprint of the ball.

If the crystal surface approximates a 1, 0, 0 plane, the depression will be surrounded by eight sets of

loops, as shown in Fig 1 A 1, 1, 0 plane also shows an eight 'looped' figure, but in this case the pattern is no longer symmetrical but appears as Fig 1 would appear if the page was stretched to $\sqrt{2}$ of its present width This, as well as the fact that a 1, 1, 1 plane shows a six 'looped' figure, is to be expected from the atomic spacing in these planes

Fig 1

The loops, of course, are simply contours either of depressions or of elevations of the crystal surface In Fig 1, the borders are parallel to the sides of the elementary crystal cube, in this case, families of loops having axes parallel to the sides of the cube represent depressions, while those with axes parallel to the diagonals represent elevations

Photographic Effects of Vitamins A and B

The biological effect of vitamins is well known, but their chemical nature is most elusive We have recently been investigating their physical effects, and some results obtained may be of interest

Photographic plates were covered with aluminium foil and letters were cut out of the foil covering the glass side Extracts of vitamins A and B, biologically tested, were used to paint the letters VA and VB on the glass side The vitamin A used was ether extract of dried ox liver, the solvent being removed in nitrogen Vitamin B was water extract of purified brewers' yeast The plates, wrapped in black paper, were left for three days, on development, clear images of the letters were obtained

To confirm the results, vitamins A and B were sealed in two separate glass tubes, and the experiment was repeated Very sharp images were again obtained

An extract of vitamin A prepared in a Paris research laboratory was investigated in the same way. It also gave positive results

Vitamins destroyed but not carbonised did not affect the plates

Two solutions, one ten times stronger than the other, of vitamin A in paraffin oil and vitamin B in water, were compared The plates showed clearly difference in strength Control experiments of pure solvents gave unfogged plates

It is interesting to note that the effect of vitamin B is similar to that of vitamin A, although the two vitamins are of different origin.

The experiments were repeated several times, and the same definite effect was present We are proceeding with our research into these effects

Isomeric Thiosulphuric Acids.

In continuation of an investigation of thiosulphatocobalt complexes,[1] it has been found possible to isolate two very interesting isomeric modifications of thiosulphato penta cyano cobaltic acid $H_4[(CN)_5\ Co\ S_2O_3]$, the difference between which lies in the constitution of the thiosulphate radical The two acids differ in their chemical behaviour and form two corresponding series of crystalline isomeric salts Both the complex acids hydrolyse in warm water, liberating two different varieties of free thiosulphuric acid One of the latter decomposes as usual into sulphur dioxide and sulphur, whereas the other gives rise to sulphuretted hydrogen and sulphuric acid This furnishes a positive and direct evidence of the existence of two isomeric forms of thiosulphuric acid, and has indeed led to their isolation in solution The two different ways in which the constitution of thiosulphuric acid has been represented in many text books correspond, therefore, in reality to these two isomeric forms In fact, Piccard and Thomas[2] obtained an indication of the synthesis of thiosulphuric acid from sulphur trioxide and hydrogen sulphide

The constitution of the two forms is best represented by the well known formulæ

Ravens Flying Upside-down.

In Nature of Dec 20, 1930, p 956, Mr Sydney Evershed has described an observation relating to ravens flying upside down From this note one gets the impression that the habit is rather rare, from my observations, however, this is not the case For some years I have had the opportunity of seeing many hundreds of these interesting birds in Iceland, where the number of individuals of this species apparently is rapidly increasing, probably because the refuse from the fisheries affords food for very large numbers of them In some places—as Westmannaeyer and Hnifsdal in Isafjord—I have seen about a hundred of these birds performing evolutions in the air round favourite resting places, and here it is a rather common appearance to see the birds flying upside-down in the manner described, though I do not think I have seen them flying for so long a distance as 1000 metres, as recorded by Mr Evershed The upside-down flight is, so far as I can judge, not particularly connected with the courtship, though it is most often seen at the time of courtship, when air acrobatics are especially performed by the birds

Photosynthesis and Solution in Formation of Coral Reefs.*

By Prof J STANLEY GARDINER, F R S

THE penetrating writers on coral reefs such as Chamisso, Darwin, Dana, Semper, L and A Agassiz, Murray, and, perhaps, Wharton could scarcely be labelled as belonging to any particular science in a modern sense In contrast, the investigator of the coral reef problem ' to day is usually either a geologist or a zoologist, for the botanist has not understood, up to the present, that he may claim an equal partnership Unfortunately, the geologist rarely has sufficient knowledge of biology, although well acquainted, perhaps, with the shapes of organisms and the possibilities of earth movements The biologist, on the other hand, has views as to the disappearance of Gondwanaland , but his writings indicate his incredulity as to any suggested existence of similar earth fluctuations to day The mobile crust of the earth allows of movements in the earth's surface , but these are more often supposed to be activated by chemical processes in the inner material than by alterations in the land and sea above In addition, there are the physical and chemical reactions of the water of the ocean, and the possibilities of these, little understood even to day are almost unconsidered

I claim that there are two primarily biological forces found together on all coral reefs and assisting to shape them Photosynthesis gives an extraordinary biological efficiency to the reef building organism and, as a result, causes an incredible rapidity of formation of limestone and thus of reef growth This is countered by the solution of limestone by boring organisms, superficially appearing small in itself, but actually a main factor in that fight between death and life that is visible on every reef

The photosynthetic method of carbon feeding in most plants, depending on their chlorophyll, is too well known to require further reference There are many halophilous phanerogams which hold the sand of surface reefs together and thus add materially to their permanency Bare rock surfaces are covered by about forty species of low growing, mostly blue green algæ that prevent their destruction

A few seaweeds such as *Halimeda*, with precipitated lime in their fronds, assist in forming deposits in the sea and may even be the chief material filling up parts of lagoons But the main reef builders are about twelve species of five genera of Lithothamnioneæ, which possess dense skeletons of lime in the composition of which magnesia up to about 20 per cent may play a part Only a thin surface film is living, the light being unable to penetrate deeply through cells which are ever depositing lime in their walls The encrusting forms thicken slowly, but push out their edges rapidly, more than 20 mm being recorded in four weeks *Goniolithon*, as finely branching growths, affects the surfaces of barrier and atoll reefs, behind the actual edge zone, which is covered almost entirely by incrusting *Lithophyllum*, pushing up into branching but rounded masses This genus is abundant in places down to 10 fathoms on the seaward slopes, but gradually *Lithothamnion* becomes the dominant plant builder, its deeper species, small branched but rather delicate detached growths, often completely covering the whole surface All genera belong to the encircling reef, atoll, or barrier, not occurring on lagoon shoals or floor

The sedentary animal builders are all cœlenterates Of first importance are corals (*Madreporaria*), the builders here being all massive or branching forms, each a single animal but with vast numbers of feeding and breeding organs in its polyps Then there are the stinging hydroid (*Millepora*) and the blue coral (*Heliopora*) which grow generally to form massive upstanding plates, the animal matter forming a surface film perpetually depositing its lime below The last is an alcyonarian and there must be added a series of forms from this group, the organ pipe coral (*Tubipora*) and the soft corals (*Sarcophytum*, *Sclerophytum*, *Lobophytum*, and *Xenia*), all of which form their lime in spicules which may play a considerable part in sand formation

In animals feeding is not so simple as in plants, and consists of three processes concerned with oxygen carbon, and nitrogen Oxygen seems to be the hydrogen acceptor in the respiration of both animals and plants A complication here is the considerably greater motility of animals, even in sedentary forms, and this implies the necessity of a more bountiful supply of oxygen as well as the casting out of waste products The last has been met by the evolution of nephridial kidneys in higher animals, but the excretion is probably a function of all free surfaces in sedentary cœlenterates calling for a special water circulation to remove such poisonous materials

These special difficulties in respect to the nutrition of coral building sedentary animals in tropical waters have been met by the taming ' of unicellular green flagellates (*Zooxanthella*) by the polyps—or the polyps being adopted by such plants—housing them as symbionts in their endoderm cells In 1896, at Rotuma I found corals from which oxygen was being given off, and subsequent observations in the Maldives and on the Sladen Expedition convinced me of the importance of this phenomenon, of which Dr C M Yonge, of the Great Barrier Reef Expedition, has recently given experimental proof. Such oxygen production on the part of these symbiotic algæ implies the formation of much carbohydrate material, and in the absence of specially rapid fission in the algæ we may infer the passage of much of this to the polyps Thus we may suppose the alga to be largely responsible both for the oxygen and for the carbohydrates required by the polyps But it is possible that the alga is of even greater importance as a scavenger which

* Substance of a lecture before the Linnean Society of London on Mar 19

thrives on the waste products of its animal The utilisation of the animal s carbon dioxide is probably of small importance for its disposal is easy, and the polyp during the daylight in which the alga s chlorophyll is alone functional is largely quiescent The utilisation of the animal s nitrogenous waste products probably provides the alga with its sole available source of nitrogen the other salts required quite likely existing as such in the protoplasm of the polyp In this connexion the absence of other non infected kinds of cœlenterates and of Polyzoa from the shallower waters of coral reefs is significant

The depth from which our coral reefs of to day grow is that at which photosynthesis is active This is about 60 fathoms for plants and 45 fathoms for the plant animals as maxima These depths fluctuate in accordance with the turbidity of the water which increases in the proximity of land masses and decreases in the Pacific and Indian Oceans from east to west probably in correlation with the eastern influx of polar waters This turbidity is largely due to unicellular algæ and a second factor is introduced by their utilisation of any carbon dioxide in the water to the detriment of reef building organisms That plants would be affected is clear and it is hard to believe that polyps would provide sufficient carbon dioxide both for their symbionts and for their lime skeletons On reefs the presumption is that their extra requirements are met by their algæ breaking up the bicarbonates of the lime saturated sea water thus amorphous lime may be found precipitated on the tissues of the free parts of the polyps Where there are active water movements it is presumably swept away in the consequently heavy mucous lubrication of the surfaces but in the deeper lagoons and in other areas of still water the lime clings to the polyps and kills them This up to the present is the only suggestion which explains why lagoons have singularly little coral and algal growth on their floors and that upgrowing shoals do not occur in lagoons except in the proximity of the passages into them

The rapidity of growth of coral building organisms is well known and independent estimates agree that a reef might grow up from 14 fathoms to the surface in a thousand years but the speed of its deposition is not material to our hypothesis The horizontal outgrowth of reefs is considerable but it depends on the extension of their foundations by their own talus material On the earth s crust below the reef there is a weight of 2½ times that of the sea water replaced by the coral reef an increase of 150 per cent Can these or the analogous weight alterations found in the formation of many geological strata be reacting on the earth s crust to produce subsidences ? We can give no reply for we have few data as to the strength of the earth s crust and as to the detailed topography of the oceanic slopes off coral reefs but no one with experience of the Pacific Ocean can doubt the activity of crustal movements even to day This question must be tested and it is not beyond the scope of the geophysicist, who should be able to tell us at what depths below atolls limestone is underlaid [by] igneous and other rocks pro

Solution of limestones is largely a chemical matter and this side has been suy dealt with in respect to the coral reef by many workers Lagoons are suppos formed by solution and by the removal of mu in suspension Generally organisms are only mentioned as providing carbonic acid gas by thei decay to help the solution The mud is accepte as an expected formation wherever land or reef occur few observations on its production having been made Yet this is of great importance since it entails the study of the decay and grinding up of coral rock in which nearly all the facts are biological current action not being considerable on reefs that are clothed by living organisms Every mass of limestone is visibly bored into by organisms—molluscs worms sipunculids sea urchins and certain barnacles Some of these grind their tunnels while others dissolve them out most using both methods

As a result of the examination of many specimens I believe it is seldom that more than 40 per cent of the mass is thus removed by these animals Larger figures were obtained from sponges but on the whole they are not such important boring organisms in tropical as in temperate seas But on coral reefs I find that all limestones massive rocks corals nullipores stones and pebbles are penetrated by a network of the finest threads which are clearly algal in nature These are the chief boring organisms of coral reefs and the primary cause of the reduction of limestone to pebble sand and mud a whole sequence of organisms aiding them They bore solely by solution and while molluscs probably bored primarily for protection many other forms may well have been seeking for the nutriment these algae provide

In living corals the boring hyphæ advance in the corallum so close to the polyps that we can even imagine the latter being thrown down to fend them off In nullipores they enter the skeleton less easily and their action is slower and less marked I have tried by various means to estimate their actions but the error factor is too great to make any figures of real value partially because I have not found bored and unbored parts of the same coral skeleton In undisintegrated coral skeletons of which the polyps were living our figures vary from 10 to 60 per cent of the coral dissolved away while in dead corals of the same species the figures are 40 to 83 per cent The last figure is exceptional because usually the coral breaks up into pebbles long before it becomes so reduced but the boring algæ still live in these until smothered by mud or consumed by sand feeding organisms In any case the solution of limestone by boring algæ is a primary feature in shaping coral reefs and one deserving of the closest investigation by modern methods applied upon the reefs themselves In particular it would be useful to ascertain whether the importance of these forms observed by me on Maldivan material is applicable generally to the formation of all coral reefs

The Nature and Origin of Ultra-Penetrating Rays.

THE meeting of the Royal Society, held on May 14, was devoted to a discussion on ultra-penetrating rays In his opening address * Prof H Geiger outlined three main lines of experimental investigation, referring first to the results of direct absorption measurements, and in particular to the very beautiful measurements of Millikan and Cameron, and of Regener, which together furnish a complete series of ionisation measurements from an altitude of 5 km down to a depth of 240 metres below the surface of Lake Constance Since, in traversing 240 m of water, a particle will make many hundreds of collisions with oxygen nuclei, it is highly improbable that the ionisation at these great depths is produced by corpuscular radiation On the other hand, the shape of the lower portion of the absorption curve is in good accord with the assumption that the ionisation is produced by photons Appropriate analysis yields the value $\mu = 0\ 02$ metre^{-1} for the true absorption coefficient of the hardest component, which, according to the generally accepted formulæ, corresponds to a quantum energy of about $3\ 7 \times 10^9$ electron volts

According to the Einstein mass energy relation, the emission of this amount of energy is necessarily accompanied by a loss of mass equal to that of two protons This fact naturally suggests that the radiation in question may arise through a new type of disintegration, taking place in a heavy nucleus, in which two protons and two electrons unite in self-annihilation If we assume that the annihilation takes place in free space, then it would appear that momentum can only be conserved during the process by the simultaneous emission of two quanta of equal energy The appearance of quanta of energy $3\ 7 \times 10^9$ electron volts would in this case signify the annihilation of four protons and four electrons, that is, a helium atom As is well known, astrophysical data appear to indicate that matter is being annihilated continuously within the stars There are, however, strong arguments against the hypothesis that ultra penetrating radiation is of stellar origin

It was pointed out in discussion by Prof F A Lindemann that only the penetrating radiation generated in the surface layers of the star is able to escape, so that even if the rate of generation of energy at the centre is no greater than at the surface, the amount of energy escaping as penetrating radiation ought to be an infinitesimal fraction of the whole, whereas the energy reaching the earth's surface in the form of the hard component alone is more than 1 per cent of the total energy of starlight. Several attempts have been made to obtain evidence of penetrating radiation coming from the sun Dr G M B Dobson referred to the recent investigation by Hoffman and Lindholm, who made a very careful series of measurements extending over about a hundred days, and found that the intensity was 0 5 per cent greater during the day than during the night Attributing the additional effect during the day to the sun, we obtain a more reasonable value for the ratio of the emission in the form of penetrating radiation to the total emission, but there still remains the problem of accounting for the enormously increased emission of the stars.

If penetrating radiation is of cosmic origin, it is therefore likely to originate not in the stars, but in the extremely diffuse matter in inter stellar space, a conclusion which might account for the absence of any marked variation of intensity of the radiation coming from different directions in space It has indeed been a very real difficulty of the hypothesis of stellar origin, that in spite of the relatively high density of matter in the galactic plane, no increased intensity is observed from this direction Prof F Regener ventured to speculate upon the possibility that the radiation which we are observing now comes principally from our own galaxy—but was generated in a previous cycle of the universe, some 10^9 years ago If the universe is closed, as Einstein supposes, such radiation might be refocused, as it were, upon the galaxy, but with sufficient blurring of the image to account for the observed uniformity of intensity

Commenting on this communication, Sir Arthur Eddington said he doubts whether the universe is sufficiently accurately spherical for the necessary degree of focusing Prof Regener claimed that at least this hypothesis had the merit of doing away with all difficulties concerned with the mode of generation of the radiation, for, in a complete cycle, the physical conditions may have changed entirely, so that interaction between matter and radiation of a kind now unknown may have been possible in a previous epoch While we may share Prof Regener's enthusiasm at the prospect of turning back a page in the history of the universe, the immediate line of advance must clearly be to endeavour to reach a solution by extending our knowledge of the universe accessible to experiment

If helium is being annihilated in interstellar space, it is just possible that the process might be detectable under laboratory conditions Lord Rutherford described how he had investigated this point by placing a number of cylinders containing helium at a pressure of 100 atmospheres round a high pressure ionisation chamber The presence of the helium certainly did not increase the ionisation by so much as 1 per cent of that due to penetrating radiation Since the mass of helium surrounding the chamber was equal to a layer of water 0 4 cm thick, it is easy to calculate, using Eddington's estimate of the total amount of diffuse matter in interstellar space, that if this matter consisted entirely of helium and was disappearing at the same rate as under the conditions of the laboratory experiment, it would only account for about one-fiftieth of the observed effects of penetrating radiation While it is possible that the complete annihilation of helium may only take place under the conditions of temperature and pressure existing in outer space, it is well to

* NATURE, May 23, p 785

remember that, in ascribing this origin to the hard component of penetrating radiation, we are presupposing the validity of the formula by which the absorption coefficient of the radiation was interpreted This formula, which only takes into account the scattering of quanta by the extranuclear electrons, has been tested very thoroughly for quantum energies up to two million volts, and found to account accurately for the observed absorption Is it not likely, however, as Lord Rutherford emphasised, that the more energetic quanta may interact also with the nucleus ?

Although this question is only just coming within the reach of experimental investigation, it appears almost certain that even quanta of two and a half million volts energy show a very marked interaction with the nuclei of the heavier elements The evidence for this interaction has emerged from a study of the γ rays emitted by thorium C″ As is well known, when a quantum is deflected through an angle θ by an encounter with an electron, its wave length is increased by an amount $\Delta\lambda = \frac{h}{mc}(1 - \cos\theta)$ Thus, however great the energy of the incident quantum, the wave length after scattering through, say, 120° will be greater than 36 X U It has been shown by Chao that if thorium γ-rays are allowed to fall on lead, and the absorption curve of the radiation scattered in a backward direction is analysed, there is, in addition, a hard radiation of wave length about 20 X U A more detailed investigation (unpublished), by G T P Tarrant and L H Gray, has shown that at a 120°, in addition to the soft scattered radiation, there are also present at least two other radiations of much shorter wave length, namely, $\lambda \sim 20$ X U and $\lambda \sim 12$ X U Similar radiations were also found when tin was used as scatterer in place of lead Moreover, by using a very inhomogeneous source of γ-rays, it was found that only quanta of energy greater than about two and a half million volts were capable of exciting the new radiation

These facts appear to confirm very fully the conclusions reached independently by Chao, Meitner, and Tarrant from direct absorption measurements, that part (at least 10 per cent) of the absorption of the thorium C″ γ-rays in heavy elements must be ascribed to the nucleus As the energy of the quantum increases, there is reason to believe that the contribution of the nucleus to the total absorption will become commensurate with that of the extranuclear electrons It is most important that this point should be settled experimentally, for it is difficult to believe that the ionisation produced at great depths is due to any other than quantum radiation, and even if this radiation is of secondary origin, its wave-length would set a lower limit to the energy of the primary corpuscular radiation At present this limit is about 4×10^9 electron volts

The second type of experiment to which Prof Geiger referred in his opening address is most naturally explained in terms of a corpuscular hypothesis It consists in observing the simultaneous discharge of two 'tube counters' by a suitable relay system Since it has been shown experimentally, using radioactive sources, that every β-particle passing through a counter produces a discharge, whereas only about 2 per cent of the γ-ray quanta are recorded, the simultaneous discharge of two counters will, apart from chance coincidences, be taken to indicate the passage of the same particle through both tubes In the experiments of Bothe and Kolhörster, two counters were arranged vertically above one another, and the number of coincident discharges was noted The ratio of this number to the total number of discharges of either counter was in rough agreement with the value calculated from geometrical considerations, so that the immediate ionising agent in the case of penetrating radiation has an efficiency in discharging the counter of something like unity On introducing a 4 cm block of gold between the counters, a reduction in the number of coincidences of only 24 per cent was observed, which is approximately the reduction that this block would produce in the total ionisation Bothe and Kolhörster concluded that since, in this case, the corpuscular radiation was of the same penetrating power as the total radiation, whereas throughout the region open to experiment a secondary corpuscular radiation is always observed to be much less penetrating than the quantum radiation which generates it, the ultra-penetrating radiation was corpuscular

Referring to possible origin of radiation of this penetrating power, Prof C T R Wilson pointed out that thunderstorms are capable of generating electrons of energy 10^9 electron volts or even considerably more, and in numbers which should be far more than sufficient to account for the observed ionisation—in fact, the problem is rather to understand why we do not observe radiation of very much greater intensity arising in this way For, from the known proportion of radioactive atoms in the air, we know that about ten β-particles will be emitted per cubic metre per second, and of these, some will be ejected in such a direction as to be accelerated by the electric field of the thundercloud From time to time the accelerated β-particle will make a close collision with another electron in which the minimum energy necessary in order that the second electron should be accelerated by the field is transferred to the latter The number of fast particles thus increases with astounding rapidity—a single β-particle making one close collision every 10 metres would generate 10^{30} particles in a distance of 1 km Though the currents through thunder clouds do not reach this figure, the total energy of all the thunder clouds in action at any instant is about 100,000 times greater than that necessary to maintain the supply of penetrating radiation reaching the earth's surface

Experiments have been performed, however which appear to give evidence against the view that penetrating radiation consists of streams of very energetic β-particles Thus Rossi, and quite recently Mott Smith, using the coincidence counting method, have attempted to deflect the rays by a magnetic field In each case, the experimen

gave a negative result, though in the experiments of Mott Smith a 10^9 volt electron should have been deflected through 2 cm on reversing the field—a deflection that would have been easily measurable Since the momentum of a proton of 10^9 volts energy is only double that of an electron of the same energy, the negative result of this experiment conflicts also with the suggestion of Prof Geiger that the radiation consists of streams of protons

Considering that the range of energy open to experimental investigation is only a few million volts, however, it is scarcely surprising that no satisfactory hypothesis can be framed to account for phenomena exhibited by radiation of 1000 million volts energy L H G

Obituary.

PROF ALFRED WEGENER

THE death of Prof Alfred Wegener, leader of the German expedition to Greenland, has now been confirmed By this event the sciences of meteorology and geophysics have lost a very valuable worker

Alfred Wegener was born on Nov 1, 1880 He studied at the Universities of Berlin, Heidelberg, and Innsbruck, obtaining the degree of Ph D, at Berlin, with an astronomical thesis He took part in a Danish expedition to Greenland under Mylius-Ericksen in 1906–8, taking charge of the meteorological work, including upper air observations with kites and captive balloons, and later summarising the observations for publication He was a brother of Kurt Wegener, well known as a balloonist, and he took an active interest in his brother's work From 1906 until 1908 the two brothers held the world's record for duration of balloon flight with a flight of 52½ hours

Wegener accompanied Col Koch to Greenland in 1911–13 As an officer of the reserve, he served in the German army during the war of 1914–18, and was awarded the Iron Cross of the second class In 1916 he was appointed to the meteorological service of the German army, and was meteorological adviser on a number of Zeppelin flights After the War he joined the Deutsche Seewarte at Hamburg, and in 1925 he was appointed professor of geophysics and meteorology at the University of Graz

Wegener's expedition to Greenland in 1929 was preparatory to the fourth, in which he perished He set out from Kamarujuk in lat 71° N, on the west coast, on April 1, 1930, and by the end of July had established a station on the central ice, about 250 miles from the coast Wegener again set out in September with Dr Loewe and a party of thirteen Greenlanders, with supplies and instruments for the observers at the central station, and he started with one Greenlander, Rasmus, on the return journey to Kamarujuk on Nov 1 His non-arrival at the coast caused no uneasiness at first, as he was thought to have stayed at the central station, and it was only in late April that a search party was sent out Wegener's body was found buried in the snow, but so far his companion, Rasmus, has not been found

Wegener's contributions to meteorology included a number of papers on the investigation of the upper atmosphere, but his best known contribution to pure meteorology was a text book, "Thermodynamik der Atmosphäre", which appeared in 1911, and of which a third edition appeared in 1928. This is a particularly valuable book, in that it emphasises the physical aspects of meteorology At the time of its first appearance it was almost the only text-book which gave a physical account of the processes of weather, and it remains a valuable part of the literature of a subject in which good text-books are rare

In recent years Wegener has been better known as the author of the theory of 'continental drift', which was set forth in 1915 in the first German edition of "The Origin of Continents and Oceans" Later editions of this book appeared in German in 1920, 1922, and 1929, it was translated into English in 1924, and has also been translated into French, Russian, Swedish, and Spanish Wegener claims that the continents are rafts of granitic rock floating in a heavier basaltic magma, and therefore free to move relative to each other and to the poles He maintains that the continents have changed their positions considerably during geological times, and so accounts for the great apparent variations of geological climates and especially the glaciation of regions now within the tropics The climatological aspects of the theory have been set out very clearly by W Koppen and Wegener in "Die Klimate der geologischen Vorzeit" It cannot be said that general agreement has been reached on this subject, as can readily be seen by reference to the report of a discussion on this and kindred topics held at the Royal Society on March 27, 1930 (see *Proc Roy Soc*, B, vol 106, p 299, NATURE for April 5, 1930, p 546) Wegener's ideas have, however, stimulated research in a marked degree, and his early death is a great loss to geophysical science

Wegener's expedition to Greenland was part of a co ordinated scheme of British, German, and American co operation in an investigation of the weather conditions over the great inland ice sheet of Greenland The British expedition made a similar attempt to that of Wegener to set up a station in the centre of Greenland, but farther south, in the latitude of Angmagssalik The narrow escape from death of Mr Courtauld shows the dangerous nature of these attempts to solve the problems of the meteorology of Greenland It is anticipated that the meteorological results obtained from the centre of Greenland and from the American station at Upernivik, on the west coast, will have important bearings upon the weather of Europe and America, as well as upon the practical problems of possible air-routes to Canada, which was a special subject of study by the British expedition D B

Dr Thomas Ashby

We regret to record the death of Dr Thomas Ashby, the leading English authority on the archæology of Rome Thomas Ashby was born on Oct 14, 1874, and was educated at Winchester and Christchurch, Oxford, where he took first-class honours in Classical Moderations and Literæ Humaniores He won the Craven Scholarship in 1897, and in 1906, the year in which he took his doctorate of letters, he was also awarded the Conington Prize

As Ashby's father resided in Rome, his interests were almost inevitably directed towards the antiquities of the city in which he spent his vacations Under the guidance of Commendatore Lanciani, at that time the foremost authority on Rome, he became an enthusiastic student of the topography and history of Rome and the Campagna When the British School at Rome was founded in 1901 he became a student In 1903, he was appointed Assistant Director, and in 1906 became Director in succession to Stuart Jones He continued to hold this position until certain administrative changes were made in 1925, and his appointment, which was triennial, was not renewed Afterwards he resided in Rome without any official appointment During the War, Ashby served with the Red Cross on the Italian Front, where his knowledge of Italian was invaluable, and afterwards was interpreter to the British Military Mission with the Italian Supreme Command

Ashby's position as an authority on the archæology of Rome from the earliest times to the Renaissance was universally recognised as unrivalled His annual contributions to the *Times Literary Supplement* on the year's archæological work in Italy were packed with information concisely expressed, which showed that he had every detail of Italian archæology at his finger ends His knowledge of his subject was encyclopædic This characteristic grasp of detail, which, however, never failed to evolve a logically reasoned general plan, was particularly to be remarked in the accounts of his work of exploration which it was his custom to contribute to the proceedings of the British Association at its annual meetings For many years he carried out excavations on Roman sites in Britain for a Committee of the British Association, and was responsible for their excavation of Caerwent (Venta Silurum)

Ashby was the author of many papers which appeared in the *Papers* of the British School and in the periodicals of learned and scientific societies In 1927, he published "The Roman Campagna in Classical Times", and revised and edited "The Topographical Dictionary of Ancient Rome" left unfinished by Prof G B Platner He was the author of several works on the archæology of Roman Italy, of which the most notable was perhaps "The Aqueducts of Ancient Rome" He also published a volume of Turner's studies of Rome in which the letterpress was worthy of the painter's genius, and a book on Italian festivals and folklore Ashby was elected a fellow of the British Academy in 1927, and since last year had been a research student of Christchurch, Oxford Those to whom he gave his friendship could appreciate a warmth of nature which was not apparent on the surface, and they will long mourn their loss

Prof E P Culverwell

By the death on April 15 of Edward Parnall Culverwell, the scientific side of the University of Dublin loses one of its most untiring supporters E P Culverwell was born in 1855 He was the youngest son of Joseph Pope Culverwell He won a mathematical scholarship in Trinity College, Dublin, in his twentieth year, and a senior moderatorship in mathematics and experimental science in 1877 He was elected to a fellowship in 1883

By his marriage with Edith, daughter of the Rev Wm Fitzgerald, Bishop of Killaloe, Culverwell became connected with George Francis Fitzgerald , a connexion which may have been in some part influential in the life long interest of Culverwell in applied mathematics and in education, Fitzgerald being a very great exponent of both

Culverwell's earlier publications were a series of papers on the "Calculus of Variations" These appeared consecutively in 1892, 1893, and 1895 in the *Journal* of the London Mathematical Society In 1895 he contributed to the *Geological Magazine* two papers on "A Criticism of the Astronomical Theory of the Ice Age and of Lord Kelvin's suggestion in Connection with a Genial Age at the Pole" These papers will be in the recollection of many who may read these lines They criticise the earlier views of Croll and of Sir Robert Ball as regards the origin of the Ice Age They brought their writer into notice as a clear headed and incisive critic It is unnecessary to recapitulate the controversy Culverwell's arguments against the adequacy of Croll's theory as explanatory of the origin of the Great Ice Age appear to the present writer as convincing They are also inimical to the adequacy of Ball's views Culverwell rightly refers to the necessity of taking into account, as additional to direct solar heat, the considerable convective transport of heat at the surface of the globe An interesting résumé of the whole subject and of the nature of Culverwell's criticism will be found in "The Quaternary Ice Age", by Dr W B Wright (Macmillan and Co) of the English Geological Survey

Later in life, in the year 1913, Culverwell published "The Montessori Principles and Practice" (Bell and Sons) Culverwell at this time was professor of education in the University of Dublin This book—now out of print—is a most interesting study of a very great subject Indeed, the book is in itself so educational that the writing of it confers on its author the status of a most effective educationist

In 1890, Culverwell published a little book on "Mechanics and Dynamics", intended as an introduction to these subjects It contains many ingenious suggestions helpful to beginners J J

News and Views.

THE King's birthday Honours List contains the names of the following men of science and others associated with scientific work *Order of Merit* Sir William Bragg, in recognition of his eminent services in the advancement of science *Knights* Dr J B Baillie, vice-chancellor, University of Leeds, Col S R Christophers, director, Central Research Institute, Kasauli, Dr W C D Dampier Whetham, fellow of Trinity College, Cambridge, Dr P C Varrier Jones, founder and Medical Director of Papworth Village Settlement for the Treatment of Tuberculosis, Prof S R Krishnan, King George V professor of philosophy, University of Calcutta, Prof H Lamb, emeritus professor of mathematics in the University of Manchester, Mr C R Peers, president of the Royal Society of Antiquaries, Mr R L Robinson, vice chairman and technical commissioner, Forestry Commission *C I E* Dr L C Coleman, director of agriculture, Mysore State, Mr A McKerral, director of agriculture, Burma, Mr C A Malcolm, chief conservator of forests, Central Provinces, India *C B E* Dr Kate Barratt, principal of Swanley Horticultural College, Kent, Mr W J Hadfield, city engineer and surveyor, Sheffield, a pioneer in modern developments of highway engineering and road surfacing, Prof H M Hallsworth, David Dale professor of economics, Armstrong College, University of Durham, Dr Alice Werner, lately professor of Bantu languages at the School of Oriental Studies, London *I S O* Mr W H Moorby, assistant civil engineer in chief, Admiralty, Mr J B Scrivenor, director, Geological Survey, Federated Malay States

SIR ARTHUR KEITH, of the Royal College of Surgeons, has kindly forwarded to us the following cable addressed to him and dated May 26 "Child's skull found in Mousterian Breccia by MacCown of our expedition —Garrod" Miss Dorothy Garrod is in charge of excavations at the caves of Mount Carmel for the British School of Archæology in Jerusalem, and the party have evidently found a child's skull of Mousterian date The only human remains of this date previously known from Palestine were the fragments of the Galilee skull found by Mr Turville Petre in 1925, and two isolated teeth found by Miss Garrod in 1928 and 1929 The race represented by these fragments was the Neanderthal, and presumably the child's skull now found will also prove to be Neanderthal

ON May 27, Prof A Piccard, of the University of Brussels, accompanied by Herr Kipfer, ascended at 4 a m from Augsburg, Bavaria, in an airtight aluminium sphere, about 2 metres in diameter, raised by a balloon which was stated when fully inflated to have the enormous capacity of half a million cubic feet Anticyclonic conditions prevailed at the time, and the balloon after remaining in the air for 18 hours fell at a spot about 160 kilometres to the south Prof Piccard succeeded in reaching a height of about 16½ kilometres, probably penetrating into the stratosphere by some four kilometres, and beating all previous records of a manned balloon or aeroplane On the descent, trouble occurred with the gas valve, and after long delay the balloon landed safely on a glacier in the Austrian Tyrol, both aeronauts fortunately escaping unhurt

THE physical problem of raising a weight of perhaps a third of a ton to a height of 16 kilometres by means of a balloon is not in itself unduly difficult, it primarily reduces itself to a question of expense But to carry observers and bring them back alive is a very different proposition, and Prof Piccard and his assistant are to be congratulated on a very notable achievement The air in the cabin was renewed by two oxygen cylinders, each capable of maintaining a good atmosphere for eight hours As was to be expected, the aeronauts suffered considerable discomforts, and one strange anomaly was that at times the *temperature inside the sphere was most unpleasantly* high while the external air was 55° C below freezing point, due to intense solar radiation in the rarefied atmosphere Prof Piccard states that the balloon rose 15 kilometres in the first 25 minutes It is somewhat startling to learn that the stratosphere can be reached by observers after only 20 minutes' travel from the ground Of the scientific results obtained it is too early to speak

PROF PICCARD hoped to obtain evidence of the cosmic rays under more favourable conditions than have previously been possible, and his contributions in this field will be awaited with interest Meteorologists will be anxious to know if he has anything to tell them about the composition of the atmosphere within the stratosphere, even the amount of water vapour present there is not known, and more knowledge would be welcome regarding carbonic acid and ozone Observations with self recording instruments on unmanned balloons have already been made of cosmic radiation, atmospheric electricity, relative humidity, etc, but it is almost certain that in these cases very much better data could be obtained by eye observations, and in addition it should be possible to study the absorption of solar radiation of different wave lengths by the atmosphere at these great heights So successful an initial attempt would lead one to hope that much useful scientific information may be gained by this method in the future

SIR FLINDERS PETRIE gave his first lecture on the results of his past season's work in southern Palestine at University College, London, on May 28 The excavations have now reached a stage which reveals Ajjul as the home of the Hyksos or Shepherd Kings The Hyksos can no longer be regarded as mere nomads living in tents For centuries they held this city, strongly fortified and a key position on the road from Palestine to Egypt, and twenty times as large as Troy It must long have been a centre of commerce between Asia and Africa, for it had developed harbours and a system of weights and measures At one point of the excavations, three storeys of buildings were penetrated Eighty rooms full of debris, but

with doorways intact and walls also intact and eight feet thick, were brought to light In the tombs, human beings, horses, and asses are buried together Among them the 'great horses', which were imported for riding, were buried with special care Among the material found in the tombs was a quantity of flat bottomed pottery of a shape entirely non Egyptian It would appear that the city was abandoned about 2000 B C, probably, it is thought, owing to malaria Sir Flinders considers that there is still work for the next fifty years on Ajjul, but financial support for the work is needed

IN this connexion, we may refer to a letter which appeared in the *Times* on May 27 over the signature of forty students whose careers "have been moulded under the Professor's guidance" Directing attention to Sir Flinders Petrie's position as a pioneer in archæological discovery and its methods and aims, whether in field work or in research at home, they remind the public of his annual expeditions to Egypt, of which the results have been published fully for the use of students and popularised by lectures and in the press Beginning with his triangulation of the Pyramids, they go on to point out, his excavations in the Delta, Upper and Middle Egypt, and in Sinai and Palestine through the Badarian, prehistoric, and dynastic ages have linked up Egypt and Europe and have revealed ancient civilisations as a connected whole This tribute, no more than is merited by a lifetime devoted, with brilliant results, to archæological research, in which a wide circle will concur, is made the ground of an appeal for financial support for the continuance of training of archæological students The two existing scholarships, one for biblical research, the other in memory of Gertrude Bell, are in need of maintenance, and money is urgently required for the actual digging in the field

FOUNDED in 1881, the Society of Chemical Industry this year celebrates its jubilee The celebrations, which will be held in London and will occupy the seven days commencing July 13, begin with a meeting at the Guildhall at which additional guests may attend provided application is made for a ticket in advance, in the evening there will be a reception by the president, Sir Harry McGowan, and Lady McGowan, at the Great Central Hotel On the following day, the annual general meeting will be held at the Royal Academy of Music Marylebone, it will be followed by luncheon by invitation of the London section, and a garden party at Teddington The evening will be devoted to receptions and a lecture On July 15, the Society's medal will be presented to Dr Herbert Levinstein, who will deliver an address, meanwhile a party will visit places of interest in London Six alternative industrial visits are planned for the afternoon, members may visit the General Electric Research Laboratories, Messrs Watney, Combe, Reid and Co's Mortlake Brewery, the works of the Wall paper Manufacturing Co, Ltd, Achille Serre, Ltd, the British Drug Houses, Ltd, or the South Metropolitan Gas Co The annual dinner will be held in the evening, when the principal guest will be H R H Prince George Since this function is reserved for gentlemen, the ladies accompanying members will be the guests of the Society at dinner and at an entertainment Various alternative engagements have been made for July 16 A party will spend the day at the Rothamsted Agricultural Research Station, other members have the choice of attending meetings for the reading and discussion of papers, or of listening to addresses delivered by two of the new honorary members One of these addresses will be delivered by Dr H Sørensen on "Hydrogen Ion Concentration"

CHEMICAL industry includes the important branch of food manufacture and control, and a party of members of the Society will be invited by Messrs J. Lyons and Co, Ltd, to luncheon, followed by visits to Cadby Hall and to Greenford In the meantime, other parties will, in the afternoon of July 16, pay visits to the National Physical Laboratory and Chemical Research Laboratory, Teddington, to the research station of the Distillers' Co, Ltd, at Epsom, to the laboratories of Messrs Burroughs Wellcome and Co at Dartford, to the Fuel Research Station at Greenwich, or to the Pyrene Co and the Firestone Tyre and Rubber Co In the evening, a reception will be given by the president and Lady McGowan On July 17, there are three all day excursions to Messrs Huntley and Palmer's biscuit factory at Reading, to the Research Station of the Anglo Persian Oil Co at Sunbury on Thames, or to Windsor Castle and Eton College, in each case the arrangements include a river trip The evening function is a reception and dance by invitation of the directors of Imperial Chemical Industries, Ltd, at Imperial Chemical House, Millbank, Westminster Oxford will be visited by road on July 18, opportunity being afforded for the inspection of the Bodleian Library, the colleges and the chemical laboratories On Sunday, July 19, Canadian and American visitors will leave for their tour of the Midlands, the Lake District, and Scotland Arrangements will be made for those who so desire to attend morning service at St Paul's Cathedral, whilst the afternoon will be occupied by visits to Hampton Court or to the Zoological Gardens Throughout the week there will be an exhibition of chemical plant and research instruments at the Central Hall, Westminster Applications for participation in the celebrations, with the appropriate fees, will be accepted until June 30 The office of the Society of Chemical Industry is at 46 Finsbury Square, London, E C 2

MMES SOPHIE BOTCHARSKY and Anna Foeringer in a short letter on page 856 of this issue describe some photographic effects of vitamins A and B observed by them It has been suggested by several observers that certain substances give off radiations to which their biological activity may be ascribed, thus Kugelmass and McQuarrie (*Science*, vol 60, p 274, 1924) found that when cod liver oil was made alkaline and oxygenated it affected an air tight photographic plate through a quartz window Other workers failed to confirm this result Drummond and Webster (NATURE,

vol 115, p 837, 1925) state that many substances undergoing autoxidation will fog a plate, vapour being given off They suggest that in Kugelmass and McQuarrie's experiments the plate was not in an air-tight container, or alternatively that the fogging was due to the fused quartz emitting a phosphorescence Daniels and Fosbinder (*Science*, Sept 18, 1925, p 266) repeated Kugelmass and McQuarrie's experiments and were unable to confirm them Peacock found that cod liver oil became fluorescent on exposure to a bright light and that there was possibly some relationship between its vitamin A activity and fluorescent power but none between the latter and its vitamin D content (*Lancet*, vol 2, p 328, 1926, and also Samson Wright, *J Physiol* vol 61, p 36) More recently Hugounenq and Couture (*Compt rend*, vol 188, p 349, 1929) found that cholesterol obtained from cod liver oil darkened a photographic plate when in contact with it or separated by a quartz (but not a glass) plate

ON June 1 the survey ship, H M S *Challenger*, built by the Admiralty for the Ministry of Agriculture and Fisheries, was floated out of dock at Chatham The ceremony was performed by Miss Addison, daughter of the Minister of Agriculture and Fisheries The construction of this ship is the outcome of an interim report of the Fisheries Committee of the Economic Advisory Council, which recommended that His Majesty's Government should undertake an organised search for new fishing grounds The ship, which has been specially constructed for exploratory work in northern waters, is an oil burning vessel, 220 ft in overall length, having a displacement of 1400 tons and a sea endurance of 9500 miles The Hydrographic Department of the Admiralty will undertake the survey work, and it is hoped that important new fishing grounds will be discovered and charted The name *Challenger* has very appropriately been chosen for the ship, to perpetuate the memory and the traditions of the famous voyage of H M S *Challenger* in the years 1872–1876 That voyage is justly regarded as having laid the foundations of scientific research at sea Although the new ship is not expected or intended to carry out, like her famous predecessor, a circumnavigation of the world, anyhow at present, and her immediate objective may make less appeal to the imagination, she starts with enormous advantages in the form of the most up to date equipment for scientific research, and may be counted on to maintain the high traditions associated with her name

MR A COURTAULD's own account of his five months' stay alone on the Greenland ice cap was published in the *Times* of May 29 The party that arrived at the station to relieve the occupants in December was faced with the alternatives of abandoning the station or leaving only one man, since the supplies of food and fuel were not sufficient for more Mr Courtauld then offered to stay alone The station was a tent, ten feet in diameter, with double walls and covered with snow, through which a metal ventilator protruded Two snow houses reached by a snow tunnel contained stores, and an outer snow wall enclosed the whole Until March, all went well in spite of heavy winds and frequent gales, but on March 21 the station was completely snowed up, and from then until the relief on May 5, Mr Courtauld was unable to leave the tent, in which he lived in darkness, without even sufficient light to see what he was eating Observations, of course, had to cease when he was cut off from his instruments Mr Courtauld notes that the temperature in January was not very low, and that on one occasion it rose to 20° F By the end of February colder and finer weather set in Fifty degrees below zero was frequently observed The lowest temperature recorded was 64° below zero The strong winds were generally from the north west The station was so completely buried that Mr Watkins' relief party found it only by the remains of its flag and its ventilator shaft projecting above a uniform plain of snow

THE Very Rev Dr W R Inge, Dean of St Paul's, delivered a Friday evening discourse at the Royal Institution on May 29 on "The Future of the Human Race" Dr Inge described in outline the England of a thousand years hence as he would like to see it The population has been stabilised at about twenty millions, and certificates of bodily and mental fitness are required of would be parents London remains as a large city, but the majority of the people live in villages and small towns Mental and physical tests form a regular part of school and university training, and the results, with family histories, are registered Physical perfection confers the prestige now given to social position Most nations are nearly self supporting and food is cheap and abundant There are no wars and the functions of the central government are almost nominal There are no opportunities for making large fortunes, and indeed there is no longer any motive for living pretentiously Hours of labour are short, but serious hobbies are encouraged Broadcasting has partly superseded lectures and concerts, and air travel has much extended, so that intercourse with foreign people is easy Dr Inge warned us, however, that civilisation contains the seeds of its own dissolution Physical evolution seems to have come to a standstill While the human brain was very immature, man began to use tools, and, if we do not take care, we are in grave danger of becoming parasites of our tools

IN his Ludwig Mond lecture at the University of Manchester on May 19, Prof William McDougall directed attention to the laggard progress in the biological sciences as compared with the rapid rate at which physical science had progressed since Galileo Psychology, economics, political science, jurisprudence, sociology really mark gaps in our knowledge or fields of possible sciences that have as yet scarcely begun to take shape or being These regions, in which chaos still reigns, must be reduced to order if our civilisation is to endure The responsibility for the backwardness of the human sciences was apportioned by Prof McDougall partly to the opposition of the churches, which he asserted still largely shape and control our

universities, to biological studies, which revealed man as a part of Nature, and to studies of his beliefs, superstitions, and customs, and partly to the general acceptance of the mechanistic theory The discoveries of physical science have multiplied mankind and added immensely to the delicacy, intimacy, and importance of relations between men and groups, but have given no guidance in the handling of the new complexities Prof McDougall considers that only the biological, and especially the social sciences founded on biology, can save us from the grave disorder and chaos that threaten us Social sciences must be actively developed into real sciences, and a science of human nature must be created Our most powerful intellects should be diverted from physical sciences into research on the biological, human, and social sciences, the attack being concentrated first upon anthropology, and an attempt should then be made to build the social sciences—especially the science of economics on the results of such anthropological research

THE progress report issued by the Radiostat Corporation is of value, as it shows that considerable advances have been made in the development of Dr Robinson's invention To the general public the 'Stenode Radiostat' wireless receiving set will be of great interest, as it provides an instrument of high selectivity which will permit the hearing of broadcasting stations the wave lengths of which are very close together When put on the market, it will provide a means of largely increasing the number of stations receivable with good quality and without interference in a given locality Under the broadcasting scheme adopted in Europe, the number of channels available between 200 and 550 metres is approximately a hundred, but the number of stations actually in use is greatly in excess of this The difficulties arising from interference are surmounted to a certain extent by assigning certain channels to groups of stations all working upon the same frequency In the United States, where there are far more broadcasting stations than in Europe, group working is only a partial remedy It has been found necessary, in addition to grouping stations, to assign to each certain hours during which it is allowed to be in operation The rapid increase in the number of high power stations, both at home and abroad, is introducing still further complications These stations have a considerable 'spread' at short and medium ranges A receiving set designed for a nine kilocycle selectivity may be completely paralysed if it is operated within twenty miles of stations like Brookman's Park, Daventry, or Moorside Edge The owner of a large and expensive set of the older type will probably find, when the projected nine high powered transmitters are working in Great Britain, that possibly Rome and Stockholm will be the only foreign stations that will be heard without interference

THE third annual general meeting of the British Society for International Bibliography was held in the Science Museum, South Kensington, on April 16 The Society exists to promote the study of bibliographical methods and the classification of information, to secure international unity of bibliographical procedure and classification; and to foster the formation of comparative and specialist bibliographies of recorded information The Society is particularly interested in facilitating the adoption of the Universal Decimal Classification of the Institut International de Bibliographie, Palais Mondial, Brussels, of which Institut the Society is the British National Section This system of classifying books and articles in periodical literature has been referred to in previous issues of NATURE During the past year the Society has enjoyed very close relations with the Association of Special Libraries and Information Bureaux, and a Joint Committee of the two institutions is actively promoting the adoption of the Universal Classification The membership of the Society includes representatives of most of the specialised branches of pure and applied science Ordinary meetings are held from time to time, but the Society makes a special feature of assisting members by personal contact and correspondence in any problems of indexing literature with which they are concerned Particulars may be obtained from the Secretary, British Society for International Bibliography, Science Library, Science Museum, South Kensington, S W 7

IT is announced in *Science* for May 15 that the American Association for the Advancement of Science, and about twenty five other scientific societies, will hold scientific sessions at Pasadena on June 15–20 This will be the eighty eighth meeting of the Association and the first of a new series of annual summer meetings The meeting will be under the presidency of Prof Franz Boas, of Columbia University, who is known for his contributions to anthropology, and in his honour a special symposium on 'The Antiquity of Man' has been arranged Prof Boas's presidential address will be on "Race and Progress" On June 17, Dr Arthur Day, director of the Geophysical Laboratory of the Carnegie Institution of Washington, will speak on "The Present Status of Seismology", on June 18, Dr C A Beard, the historian will speak on "Scientists and History", and on June 19, a symposium on "The Impact of Science upon Civilisation, Past, Present, and Future", will be held Another interesting symposium has been planned on "Oceanographic Problems", and will be conducted by Dr T Wayland Vaughan A special session of the zoologists and biologists in honour of a former president of the Association, Dr David Starr Jordan, who has just celebrated his eightieth birthday, has been arranged

THE Annual Report for 1929–30 of the Scottish Marine Biological Association shows the laboratory of the Millport Marine Station to be in a flourishing condition So much have its activities increased that more accommodation will almost certainly be required in the near future Already four new tanks for live specimens have been added and more space has been made available for storage Much good work has been done, as is shown by the list of published work Miss S M Marshall and A P Orr have continued their researches in diatoms, studying for another year the spring increase in Loch Striven H B Moore has been

investigating the sea mud in the Clyde sea area, with important results, and R G Neill has completed and published a paper on the habits and feeding mechanisms of the polychæte *Nephthys cæca* Dr J A Cranston and Dr B Lloyd have isolated one of the denitrifying bacteria from the Clyde sea area, the cultural characters of which do not conform entirely with those of any known species This has been studied in detail and a type culture has been lodged with the National Collection of Type Cultures at the Lister Institute Researches have also been made on the spat fall and rate of growth in certain molluscs, and shore surveys have been continued Vacation courses for students are steadily growing in importance, and demonstrations or addresses have been given by the staff to classes and parties from various organisations

A PROPOSAL for the institution of national parks in Africa for the preservation of wild life is made by Major R W G Hingston in a paper in the *Geographical Journal* for May The spread of cultivation, the demands of trade, and the activities of the sportsman are seriously depleting the fauna Several large animals have been exterminated by human agency They include the blaubok, the quagga, and Burchell's zebra The white rhinoceros, the gorilla, the nyala, and Grevy's zebra are on the verge of extinction Game reserves, of which several exist in Africa, are useful but not entirely effective, because they have not a permanent status At present there are only two areas that have the status of national parks These are the Kruger National Park in the Transvaal and the Parc National Albert in the Belgian Congo Major Hingston outlines a scheme of nine other national parks These are (1) South Central park, including the Kasungu game reserve in Nyasaland, (2) Nyala park, two small areas in the south of Nyasaland which are both reserves, (3) Selous park, now the Selous game reserve of Tanganyika, especially for the preservation of the elephant, (4) Serengeti park, to the south east of Victoria Nyanza, which would shelter many species of grassland animals, (5) Kilimanjaro park, at present a game reserve, (6) Kenya park, to the south east of Lake Rudolf, (7) Bongo park, on the Aberdare mountains north west of Nairobi, (8) Bunyoro Gulu park, now a reserve, on the north east of Lake Albert, around the Victoria Nile, and (9) Gorilla park, in the Kivu district, for the preservation of the gorilla

"THE Animal Year Book," vol 1, 1931, is a work of information and of reference issued by the University of London Animal Welfare Society, the object of which is the furtherance of a "proper understanding of the right relationship between man and the lower animals" It contains an excellent summary of the law of Great Britain relative to cruelty to animals, a series of short notices of the state of animal welfare in some foreign countries, and useful articles upon various aspects of the cruelty problem Occasionally there is a tendency to push propaganda at the expense of truth, as when the suffering of trapped fur animals is stated to be roughly comparable to crucifixion (p 90), or when the snaring and trapping of rabbits are said to be on a par with the medieval torture of human beings (p 104), but such statements are exceptional, and the definite aim of the Society to deal with the prevention of cruelty in a reasonable way will commend itself to many sympathisers In one of the book reviews—a special feature of the Year Book—reference is made to recently invented, and presumably effective, humane rat traps (p 152) May we suggest that the illustration and description of such implements would make a most informative and useful appendix to such a work as this

THE introduction of the fur bearing musquash to Scotland for breeding purposes, and the subsequent escape from captivity of some of the animals, may have serious consequences T M Munro states, in the *Scottish Naturalist* for May, that in three different areas musquash have escaped and have made themselves at home in the open Indeed, in one area, near the banks of the Allan, as many as sixteen musquash 'houses' were in existence, until floods in 1929 washed most of them away Other localities are at Thornhill, Dumfries, and on the Bervie water in Angus, but the present writer failed to trace any wild musquash in the latter district during a recent visit The risk of the introduction is that the creature may find the climate congenial and may spread, to the destruction of river embankments and crops On the other hand, it may find it difficult simply to keep up the standard numbers We cannot tell, but it is wise in such a case to err on the safe side

THE preservation of photographs of scenery and of natural history events has become an acknowledged part of the business of the great museums, and such collections may become invaluable for reference in the future But their present value also is often very great What could be more informative in its own line than the series of photographs published in the *Natural History Magazine* for April, illustrating the shelters and beds built by gorillas for their nocturnal rest? Few people have seen these simple structures and photographs of them are real additions to scientific knowledge The pictures form part of an album of enlargements of photographs taken in the Beringa mountains, north east of Lake Kivu, by Mr Marius Maxwell, and they were presented by him to the Department of Zoology of the British Museum (Natural History)

THE conquest of a fatal disease, leukæmia, appears to be within sight This disease is not common, though every hospital of any size is likely to have at least a case or two every year, it is characterised by an enormous increase in the leucocytes or white corpuscles of the blood According to a recent *Daily Science News Bulletin* issued by Science Service, Washington, D C, Dr Hueper and Miss Mary Russell, working in the Cancer Research Laboratory of the University of Pennsylvania, have grown the leukæmic leucocytes in tissue culture outside the body, and treating rabbits with these cultures a serum is obtained which inhibits the increase of white cells *in vitro* and also in the body One human case of the disease has been treated with this 'anti-leukæmic' serum, with remarkable improvement

The report of the Irish Radium Committee for 1930 was presented before a meeting of the Royal Dublin Society held on April 28 The recent purchase of an additional half gram of radium has rendered possible a large increase in the amount of radon available, with a consequent increase in the number of patients treated The death of Dr W Stevenson, who was one of the pioneers of radium treatment, has, however, prevented the publication of his report on several hundred patients who were treated by him in 1930 Reports by other users give particulars of the treatment of 311 malignant and 44 non-malignant cases In many cases highly satisfactory results were obtained The difficulty of obtaining any information as to the state of patients who have returned to their homes in the country after treatment in Dublin hospitals presents, however, a serious problem

Referring to the population problem of Tyneside, we suggested (Nature of May 16, p 756) that the situation might possibly be readjusted by revival of local industries instead of by loss of population In this connexion, it is of interest to learn that the Department of Economics of Armstrong College, University of Durham, has undertaken, at the request of the Government, an economic survey of the industries of the north east coast of England The purposes of this research are to examine the existing industries of the area and to determine whether any of them are ever again likely to employ the same amount of labour as in the past, and to inquire into the possibilities of establishing new industries to absorb surplus labour The conclusions arrived at will be put before the Council of Armstrong College towards the end of the year and forwarded to the Government The Universities of Glasgow, Manchester, and Wales (Cardiff) have been asked to conduct similar surveys of their areas

The eighty fourth annual meeting of the Palæontographical Society was held at Burlington House, London, on May 29, Dr F A Bather, president, being in the chair The annual report recorded the publication of instalments of the monographs on Corallian Lamellibranchia, Gault ammonites, Palæozoic Asterozoa, and macrurous Crustacea It also announced the completion of the macrurous Crustacea in the next annual volume, and the publication of a second supplement to Girvan Trilobites Prof P G H Boswell, Prof H L Hawkins Dr C J Stubblefield, and Mr W F Swinton were elected new members of council, and Dr F A Bather, Mr Robert S Herries, and Sir A Smith Woodward were re elected president, treasurer, and secretary respectively The president delivered a brief address on phylogeny and classification, during which he expressed doubts as to the value of a classification based on phylogeny

The Thomas Young Oration of the Optical Society will be delivered at the Imperial College of Science and Technology, South Kensington, on Thursday, June 11, at 8 P.M., by Sir John Parsons, who will take as his subject "Young's Theory of Colour Vision"

The Huxley Memorial Lecture, 1932, of the Imperial College of Science and Technology will be delivered by Mr. Aldous Huxley, on "Huxley as a Literary Man", in the Royal College of Science, Exhibition Road, S W 7, on Wednesday, May 4, 1932, at 5 30 P M

At the anniversary meeting of the Linnean Society of London held on Thursday, May 28, the following officers were elected —*President* Prof F E Weiss; *Treasurer* Mr Francis Druce, *Secretaries* Mr John Ramsbottom (Botany) and Lieut Col John Stephenson (Zoology) The Linnean Gold Medal was awarded to Prof Karl Ritter von Goebel

At the spring convocation on May 6, the doctorate of laws was conferred by Queen's University, Kingston, Ont, Canada, on Dr H T Gussow, Dominion Botanist and Chief of the Phytopathological Service of the Dominion of Canada Dr Gussow has also been honoured by being elected a fellow of the Royal Society of Canada

Prof C H Desch has been appointed superintendent of the Metallurgy Department of the National Physical Laboratory, in succession to Dr W Rosenhain Prof Desch is at present professor of metallurgy, and Dean of the Faculty, in the University of Sheffield, and was formerly professor of metallurgy in the Royal Technical College, Glasgow He is a past president of the Faraday Society and of Section B (Chemistry) of the British Association Prof Desch will not take up his new appointment until February 1932, as he had previously accepted an invitation from Cornell University to give a course of lectures there during the winter session of 1931–32

The following appointments have recently been made by the Governing Body to the staff of the Lister Institute of Preventive Medicine Dr A Felix (research fellow in bacteriology), to be assistant in the Department of Bacteriology, Dr J M Gulland (University demonstrator in chemistry at the University of Oxford), to be first assistant in the Department of Biochemistry in succession to Dr R Robison, who became head of the department on Jan 1 last, Marjorie G Macfarlane (Carnegie research fellow), to be temporary assistant in the Department of Biochemistry, and Adèle H Rosenheim (Grocers' Company research student), attached to the same department, Douglas McClean (research fellow in bacteriology), to be assistant bacteriologist in the Department for the Preparation and Study of Antitoxic Sêra, Elstree, Hester M Jackson, to be temporary assistant in the Division of Nutrition, Dr G P Wright, to be research fellow in experimental pathology

We have received from Messrs James Swift and Son, Ltd, 81 Tottenham Court Road, W 1, their new catalogues of petrological microscopes and accessories for the petrological microscope The former lists instruments of varying degrees of complexity, from the 'Primex' designed to meet the requirements of the student to the 'Dick' and 'Graham-Dick' instruments adapted to the needs of the advanced worker. In all the models, the fine adjustment with single milled head at the back has been retained, but one actuated by lateral milled heads will be supplied if desired A stereoscopic binocular

on the Stephenson principle is also in the catalogue Of accessories, we note a series of micrometers and Shand's recording micrometer, goniometers of various types and complexity, and drawing and illuminating apparatus

A LIST (No 16) of nearly 600 second hand books of zoological, botanical, and horticultural interest has just been issued by Mr J H Knowles, 92 Solon Road, S W 2

A SHORT list (" Periodica ", Supplement 1) of scientific periodicals offered for sale by W Dawson and Sons, Ltd , Pilgrim Street, E C 4, has just reached us It should be of interest to anyone wishing to add to their scientific library or to complete imperfect sets of periodicals

APPLICATIONS are invited for the following appointments, on or before the dates mentioned —A technical administrative officer under the Leeds Education Committee, for secondary and higher education—The Director of Education, Calverley Street, Leeds (June 10) A lecturer in the department of building of the Birmingham Central Technical College - The Principal, Central Technical College, Birmingham (June 12) A full time teacher of electrical engineering subjects and chemistry at the Kingston upon Thames Junior Technical School—The Principal Technical College, Kingston upon Thames (June 13) A head of the boot and shoe department of the County Technical College, Stafford—The Clerk to the Governors, County Education Offices, Stafford (June 20) A head of the department of industrial administration of the Manchester Municipal College of Technology —The Registrar, College of Technology, Manchester (June 22) A headmaster of the Exeter Junior Technical School—The Secretary for Education, 39 Southernhay West, Exeter (June 22) A temporary principal technical assistant in the Shellfish Services staff of the Fisheries Department of the Ministry of Agriculture and Fisheries—The Secretary, Ministry of Agriculture and Fisheries, 10 Whitehall Place, S W 1 (June 22) A lecturer in economics in the Durham Colleges—The Secretary to the Council of the Durham Colleges, 38 North Bailey, Durham (June 23) Assistant lecturers in geology and mathematics in the University of Sheffield—The Registrar, University, Sheffield (June 24) A gas research Radiation, Ltd follow, at the Imperial College of Science and Technology—The Registrar, Imperial College of Science and Technology, South Kensington, S W 7 (June 26) Junior lecturers in, respectively vertebrate embryology and cytology in the University of Edinburgh—The Secretary to the University, Edinburgh (June 26) A laboratory steward in the physics department of the Imperial College of Science and Technology—The Secretary, Imperial College of Science and Technology, South Kensington, S W 7 (June 30) A research student in biochemistry at the Lister Institute—The Secretary, Lister Institute Chelsea Bridge Road, S W 1 (July 1) A lecturer in chemistry and botany at the Studley Horticultural and Agricultural College for Women- The Principal Studley College, Warwickshire A young master for science and mathematics at the Beacon Hill School—Bertrand and Dora Russell, Harting, Petersfield A senior science master at St Lawrence College, Ramsgate—The Headmaster, St Lawrence College, Ramsgate

Our Astronomical Column

Calendar Reform - The *Scientific American* for June contains an article by G Eastman strongly advocating the adoption of a year of thirteen months with 28 days in each, and an extra day at the end, not to reckon as a weekday , in leap year there would be a second extra day, which would be placed at the end of the sixth month , each month would always begin with a Sunday There is no question that such a calendar would be convenient to such astronomers as have occasion frequently to reckon the interval in days between given dates , the want of system in the lengths of our present months, and the position of the leap day at the end of the second month, instead of the end of the year, are serious drawbacks But the interruption of the regular sequence of weeks, which have now been running without a break for some three thousand years, excites the antagonism of a number of people Some of these (the Jews, and also many Christians) accept the week as of divine institution, with which it is unlawful to tamper ; others, without these scruples, still feel that it is useful to maintain a time-unit that, unlike all others, has proceeded in an absolutely invariable manner since what may be called the dawn of history This view found strong support at the meeting of the International Astronomical Union at Rome in 1922 , and it is unlikely that there will be, at least in the near future, sufficient consensus of opinion to enable the scheme described above to be carried through

Mr. Eastman outlines a second scheme, which does not interfere with the week , this makes an ordinary year exactly 52 weeks, and inserts an extra week every fifth year (with occasional variations akin to the Gregorian centennial year regulations) The fact of making some years a week longer than others would however, involve difficulties in the regulation of salaries the variation of the equinoxes and solstices by a week would also give trouble in meteorology

To sum up every scheme involves so many controversial points that it is unlikely that any change will be made unless the calendar reformers confine their demands to more moderate limits

Light Variation of ε Aurigæ - This star is of special interest from the great length of its eclipses (assuming, as is usually done, that the light variation arises in this manner) *Astr Nach* 5784 contains a series of observations made at Bologna Observatory by Dr L Jacchia The following are his dates for the phases beginning of eclipse, May 13, 1928 , beginning of stationary minimum, Oct 22, 1928 , middle of eclipse, April 25, 1929 , end of stationary minimum, Oct 25, 1929 , end of eclipse, April 15, 1930 The light-variation includes secondary waves, their presence being confirmed by M Gussow, using a photoelectric cell , as a result of them, the increase of light was slower than the decrease The mean magnitude at maximum is given as 3 23 , at minimum, 3 88 The extreme points on the light curve are 3 13 and 3 94 Five stars in Auriga and Perseus, of magnitudes between 2 72 and 4 78 (Harvard) were used as comparison stars

Research Items.

Roman Pottery Kilns in Yorkshire.—The investigation of a Roman pottery kiln site at Throlam Farm, near Holme on Spalding is recorded in the *Transactions* of the East Yorkshire Antiquarian Society, vol. 27, pt. 1, by Mr. T. Sheppard and Mr. P. Corder. The site is a mound, about a hundred feet in circumference and about six feet above ground level, consisting almost entirely of wood ash and sherds. Near the centre is a mass of puddled clay forming a mound 14 ft. by 7 ft., stratified into clearly marked layers by bands of black ash and sherds, representing successive occupations or reconstructions. On the west end of this are two roughly constructed kilns, 3 ft. 6 in. and 2 ft. 7 in. in diameter respectively, which were fed from the same stokehole. They were constructed on the oven floor of an earlier and larger kiln which was itself superimposed on another. This larger kiln has been almost completely preserved. It differs from the usual type of small Roman pottery kiln only in certain particulars. No pit was excavated, but a mass of puddled clay was dumped on the floor of the kiln, and from this the later kiln was fashioned. The floor was supported on pillars which divided the furnace into three. The pottery, with the single exception of a Samian sherd, is of the Yorkshire coast Signal Station type of the last part of the fourth century; but as the bulk of the pottery is earlier than that of Huntcliffe or Scarborough, the most probable date is the later half of the third century.

Blood Standards for Indians.—In the course of study of anæmia in the Bombay Presidency, it was realised that no normal standards for Indians are available with which pathological findings can be compared. Even accepted European standards are found to present considerable variations in different text-books. Major Sokhey and his assistants have therefore examined 121 healthy young Indian men and 101 women living in Bombay by approved methods and with specially standardised apparatus (Report of the Haffkine Institute for the year 1929, p. 26, Bombay, 1931). The following averages have been obtained:

	Men	Women
Red cell counts, millions per cubic mm.	5·11	4·47
Hæmoglobin—grams per 100 c.c. of blood	15·36	12·99
Volume of cells, c.c. per 100 c.c. of blood	41·72	36·27

Isolation of Sexes in Bird Movements.—In a short paper in the *Naturalist* (May 1931, p. 145), Noble Rollin is able to confirm the statement that as a rule female birds form the vanguard in migration, and that the males show a tendency to lag behind. The result is the more interesting because it has been found amongst birds in which the sexes cannot be determined by examination in the field. Birds were collected at random in the neighbourhood of South Shields and grouped themselves in a series of six common land birds and seven waders and sea birds, a mixed bag of migrants and partial migrants. The sex was determined by dissection. On the whole, the results revealed by the two sets of records are very consistent. It would appear that during late autumn (October and November) the stock of birds is predominantly female, whereas in the winter (December and January) it is predominantly male. The curve in which the results are expressed illustrates the instability of the bird population of an area during autumn and winter, and this is apparently due to sexual dimorphism in the migratory movement.

Golgi Bodies and Yolk.—Allahabad University Studies, vol. 6, pt. 2 (Science Section), 1930, contains contributions from the Departments of Zoology, Chemistry, Botany, and Mathematics. Five of the seven zoological papers are on the cytology of oogenesis respectively of tortoises, the gecko, *Pila* (apple snail), frogs and toads, and fishes. In the tortoise, "fatty yolk is formed directly and indirectly by Golgi bodies", while albuminous yolk is formed either "by direct metamorphosis of mitochondria into a yolk body" or by other activity of the mitochondria; nucleolar extrusions take no part in the formation of yolk. In the gecko the Golgi bodies 'appear to play no part whatever in vitellogenesis". In *Pila*, the Golgi bodies contribute directly or indirectly to the formation of fatty yolk spheres; later the mitochondria multiply rapidly, swell, and give rise to true yolk spheres by a process of direct metamorphosis. In the frogs and toads, the Golgi bodies appear to take part in the formation of fatty yolk, though whether by direct metamorphosis was not determined. The true yolk is formed by the metamorphosis of mitochondria. In the fifth paper is described the infiltration of Golgi bodies, either in "big lumps or as is more frequent, in the form of granular bodies", from the follicular epithelium through the zona radiata into the oocyte of the fishes *Saccobranchus fossilis* and *Ophicephalus punctatus*.

Hard Fibre Production within the Empire.—An interesting lecture upon this subject by Mr. Alfred Wigglesworth is reproduced in the *Journal* of the Royal Society of Arts, vol. 79, No. 4087, Mar. 20, with an abstract of the interesting discussion that followed the lecture. The hard fibres referred to occur in the leaves of monocotyledons, and for many purposes they are now being exploited, at the expense of the fibre from the inner fibrous bark of dicotyledonous plants such as flax and hemp. They include New Zealand flax, *Phormium tenax*, *Furcræa gigantea* (mainly exported from Mauritius), and *Agave cantala*. In every case, the successful introduction of such a hard fibre depends upon the development of methods for the separation of the comparatively small amount of fibre from the tough leafy tissues; and the rapid development in recent years of the hard fibre trade is very largely due to the success with which the problem of the large scale extraction of sisal fibre has been attacked. Sisal has long been cultivated in Mexico, but in 1836 Mr. Perrine transported suckers to Florida. From the Florida plants, by vegetative propagation practically the whole area now under sisal outside Mexico, in East Africa, Dutch East Indies, etc., has been supplied. Mr. Wigglesworth points out that there is ample room for scientific study of the breeding, cultivation, and methods of extraction, purification, and grading of all these fibres. One point of great interest is that the sisal fibre has a larger cell lumen than the Manila fibre (from *Musa textilis*) and Mr. Wigglesworth thinks that this explains why sisal absorbs more water—and more rapidly—than Manila fibre. The *Bulletin* of the Imperial Institute, vol. 29, No. 1, 1931, contains a report of the effect of sea-water on the strength and durability of sisal hemp in comparison with Manila. Three series of trials have been completed and the results afford clear evidence that East African sisal has satisfactory durability in sea water.

The Wilberforce Radium Occurrence.—Under this title, H. S. Spence and R. K. Carnochan have recently described the richest deposit of radium ore yet found

in Canada (Dept of Mines, Canada *Investigations of Mineral Resources and the Mining Industry, 1929*, Ottawa, 1930, pp 1 23) The ore consists of uraninite disseminated in large crystals and aggregates through strings and long miarolitic pockets of calcite and fluorite, with subsidiary apatite, occurring in a syenite pegmatite, which itself contains large pockets lined with felspar crystals The uraninite bearing 'lead' is considered to be at least 500 ft long by 5 12 ft wide Tests on a carload of ore showed that 1 gm of radium would be recoverable from the concentrates separated from 3422 tons of ore This result, and the development work carried out in the field, suggests that the occurrence has commercial possibilities An analysis by Ellsworth of the uraninite shows U_3O_8, 61 64 per cent, ThO_2 13 56 per cent, and PbO, 11 05 per cent, corresponding to an age of more than 1200 million years It is of interest to record that, according to reports recently published in Montreal, pitchblende deposits have been found at Echo Bay on Great Bear Lake, 750 miles by river navigation from the railhead at Waterways, Alberta

A Survey of Niagara Falls A phototopographical survey of Niagara Falls was carried out in 1927 by the Geological Survey of Canada, and is fully described by Mr W H Boyd in *Memoir* 164 of the Geological Survey Work on the American Fall was comparatively easy since, owing to the small volume of water, the rock crest is visible from end to end In the Horseshoe Fall, however, the central part is completely covered and offers no points of identification To overcome this difficulty, three cameras, one at each of three stations, were exposed simultaneously Thus the appearance of the water along the width of the crest was revealed at the same instant from each of three stations It was found to be easy to identify the same points of the water face in all the three photographs Thus the crest could be mapped Elevations along the crest line were also taken Details of the methods employed are given in a pamphlet accompanying the surveys

The Queen Maud Range, Antarctica —This huge faulted range of mountains at the south eastern end of the Ross Sea was discovered by R Amundsen in his march to the South Pole in 1911 He charted roughly only a limited area on a small scale, for his field of vision was naturally limited Amundsen's map appeared in his book "The South Pole" (1912) Admiral R E Byrd crossed the range to the west of Amundsen's route in his flight to the South Pole in 1929 From his height, the range of vision was considerable The survey material from his aerial photographs was amplified by Prof L M Gould's sledge journey along the base of the range From all the available data, the American Geographical Society has produced a contoured map of the Queen Maud Mountains on a scale of 1 500,000, which is about ten times the scale of Amundsen's map (*Geographical Review*, April 1931) Positions are fixed from three astronomically determined points at which wireless time signals were observed The map reveals three immense glaciers, named Amundsen, Thorne, and Leverett, comparable in nature with the Axel, Heiberg, and Liv glaciers of Amundsen and the Beardmore glacier of Shackleton It gives the trend of the Queen Maud Range a more easterly direction than Amundsen had observed and disposes of his Carmen Land The map is a valuable contribution to Antarctic cartography

An Exceptional Night Sky —Lord Rayleigh, in the May number of the *Proceedings* of the Royal Society, describes an unusual night sky which was watched by him at Terling (52° N) on Nov 8, 1929 The light was much the same in constitution as on ordinary nights, extending uniformly over the sky, but was very much brighter than usual, and of constant intensity over a period of hours Its spectrum seemed continuous, and the green auroral line (λ5577) was not definitely seen It was evidently of a totally different nature from the polar auroral light, and, confirming this distinction, the state of the earth's magnetism was steady The negative bands of nitrogen could not be searched for on this occasion, as they were outside the range of the spectroscope used, but Lord Rayleigh says that in his experience the most striking distinction between the ordinary night sky and the polar aurora is the absence of the bands from the former, a contrary conclusion has, however, been arrived at by Sommer, who finds that these bands are present in the normal night light at Gottingen Lord Rayleigh has remeasured the two unidentified lines (or band heads) in the night sky spectrum at λ4419 and λ4168

Recombination of Cæsium Ions —The information afforded by quantitative study of recombination of electrons and ions is of very great value in testing theories of many atomic processes, giving essentially the effective cross section of an atom or ion under various conditions An account of an investigation of the recombination of cæsium ions and electrons to form normal ($1\,^2S$) atoms of cæsium, given by C Boeckner in the February number of the Bureau of Standards *Journal of Research*, is of particular importance because it verifies the fact that the normal state of cæsium is anomalous in its behaviour, recombination into two of the excited states of cæsium ($2\,^2P$ and $3\,^2D$) takes place in the simple way which would be expected from the quantum theory of the hydrogen atom, whereas recombination into the more tightly bound $1\,^2S$ state follows an entirely different law The results were obtained by Mohler's method of measuring the intensity of the continuous recombination spectra which appear at the series limits, simultaneously with a probe wire analysis of electron velocities by Langmuir's method, and furnish incidentally a proof of the correctness of the current theory of exploring electrodes

Electrical Resistance of Moisture Films on Glazed Surfaces —In measuring the electrical resistance between two conductors separated by a mass of insulating material, it has long been known that the apparent value of the resistance depends on the humidity of the air and the previous history of the insulator It is usual to divide the current which flows between the two conductors into two components, one flowing through the insulator and the other through a film of moisture or other conducting material on the surface of the insulator In actual tests, the relative values of these two currents vary largely, since water, even when very pure conducts much better than ordinary insulators the surface leakage current may be many times greater than the component which flows through the solid insulator In a paper published in the March number of the *Journal of the Institution of Electrical Engineers*, G G Small, R J Brooksbank, and Prof W M Thornton discuss how the electrical resistance of moisture films on glazed surfaces varies with the resistance, temperature, and vapour pressure of the surrounding medium Their experiments show that there is a very sharply defined critical pressure above which the resistivity falls as the pressure rises, and below which they both fall together The drop of voltage down a string of insulators depends on the

surface resistance as well as the capacitance of the units When a steam jet is played on the string until there is a complete deposit of visible moisture, the voltage gradient becomes a straight line The potential to earth of the lower units is sometimes more than doubled Stabilising devices, therefore at the earthed end of the string of insulators may be more effective in preventing flashover on the string The experiments show that water films are deposited or adsorbed on glazed surfaces long before they are visible as dew

Ohm's Law for Electrolytes —Experiments made in 1927 by Wien on electrolytic conduction in fields of 30,000-300,000 volts per cm indicated an increase of conductivity with field strength, amounting to as much as 50 per cent These results have been interpreted in the light of the modern theory of strong electrolytes, by assuming that in the case of high ionic velocities there is no opportunity, or only a restricted opportunity, for the ion atmosphere of opposite sign to build up around the moving ion so that the retarding effect of this atmosphere, giving rise to a change of equivalent conductivity with dilution, is not fully exerted More recently, Wien has found the effect for field strengths so low as 3000 volts per cm These experiments show that Ohm s law is not valid for electrolytes over the entire range of voltages Although it would not be expected in the case of the low field strengths used in the Kohlrausch method of determining conductivities, a change of resistance with applied voltage has been reported by Parker In the April number of the *Journal of the American Chemical Society* Jones and Bollinger show that with low field strengths the voltage used is without effect on the measured resistance over a wide range of frequencies and of resistances, and with cells of widely varying design Ohm's law may, therefore, be regarded as valid for electrolytes under these conditions

The Nature of the Chemical Bond —Recent applications of quantum mechanics have led to an approximate calculation of the energy of formation and other properties of very simple molecules, such as H_2, and have provided a formal justification for the rules stated by G N Lewis in 1916 for the electron pair bond Linus Pauling, in the April number of the *Journal of the American Chemical Society*, extends these applications and supplements Lewis's rules for the electron pair bond by new rules which provide information regarding the relative strengths of bonds formed by different atoms, angles between bonds, free rotation or lack of rotation about bond axes, etc A detailed theory of the magnetic moments of molecules and complex ions is also developed, the value of μ being given by $2\sqrt{S(S+1)}$, where S is the total spin angular momentum, the moment being determined entirely by the number of unpaired electrons This relation, which does not apply to rare earth ions, makes it possible to decide from magnetic observations between electron pair bonds and ionic and ion dipole bonds for various complexes The tetrahedral carbon, nitrogen, and phosphorus atoms in appropriate compounds are reproduced, and the known results for rotation about single bonds (except when restricted by steric effects) and lack of rotation about double bonds follow Several examples of the determination of structure from a knowledge of the calculated angles between bonds are given On the theoretical side, special attention is directed to the effect of concentration of the bond eigenfunctions The type of bond formed by an atom is dependent on the ratio of bond energy to energy of penetration of the core When this ratio is small, the bond eigenfunctions are p eigenfunctions giving bonds at right angles to one another, but when it is large, new eigenfunctions especially adapted to bond formation can be constructed

Metallic Corrosion —Two papers communicated by Sir Harold Carpenter to the Royal Society, and published in the May number of the *Proceedings*, furnish a great deal of information about the mechanism of corrosion of metals The first, by U R Evans, L C Bannister, and S C Britton, is on the velocity of corrosion from the electrochemical point of view Currents flow between anodic and cathodic parts of corroding metals, and it has been shown that the currents measured are equivalent to the corrosion produced, the problem of corrosion speed being thus largely reduced to a study of the electrochemical factors which determine this current One of the important factors which enters is polarisation set up by the current, it occurs in most cases at the cathodic area, and is due to limitations in the rate of supply of oxygen When corrosion starts at a weak point in an invisible film covering the surface of a metal, the area being attacked changes until the current density over it is equal to a certain ' protective value ', which is the current density which will cause any incipient attack on a weak point within the area in question to lead to a precipitation of rust so close to the surface as to seal the defect, a principle made use of in the ' cathodic ' method of preventing corrosion The second paper, by G D Bengough, A R Lee, and F Wormell—the fourth of a series on the theory of metallic corrosion—is chiefly upon the effect of oxygen upon zinc immersed in potassium chloride solutions, and shows that the action cannot be completely explained by the difference in oxygen concentration which had been postulated in the ' differential aeration ' theory Zinc hydroxide plays an important part in the reactions, both in a thin film which adheres closely to the metal and is impervious to oxygen and zinc ions, but not to electrons, and in the loose masses which appear, and do not completely stop the passage of oxygen

The Protection of the Underwater Hulls of Ships — The possibility of producing a hard smooth surface on the underwater hulls of ships which would remain smooth has long been regarded as desirable, for such a surface would lead to a great economy in fuel This is one of many subjects touched upon in a paper on " Modern Developments in Ship Design ", by Dr J Tutin and A C Hardy, contained in the January number of the *Transactions* of the Institute of Marine Engineers The authors state that marine growths cannot in general attach themselves to hard surfaces such as glass, porcelain, and clean steel Is it too much, therefore, they asked, to expect modern chemical research to provide an anti corrosive composition with an ultra-hard surface? In a written communication, contained in the *Transactions*, P Jenkins, chief chemist to Messrs J Dampney and Co, Ltd, stated that he thought the theory that marine growths do not adhere to hard surfaces is doubtful, in the Hancock Museum, Newcastle, is a bottle encrusted with beautiful specimens of barnacles All paints and compositions have of necessity to contain oily matter to repel water, and such materials cannot be made very hard It is, therefore, too much to expect chemical research to find an ultra hard preservative for ships' hulls The only coating of this nature which can be applied to iron is vitreous enamel, and this is impracticable for the protection of ships Vitreous enamels are fused at high temperatures and are applicable to only relatively small objects They are also prone to chip off

Statistics of the Universities of Great Britain.

TO the Returns * from Universities and University Colleges for the academic year 1929–30 the University Grants Committee prefixes an introductory note which serves to bring up to date the quinquennial review issued by the Committee last year and commented on at some length in NATURE of Aug 2, 1930

The total number of full time students, of both sexes, which increased by 7 per cent in the preceding five years, shows a further increase (to 45 603) of nearly 3 per cent, whilst the proportion of women students, which declined during those years from 31 4 to 29 1 per cent, shows a further drop to 28 3 per cent The regional distribution of the increment registered in 1929–30 was England 914 (879 men), Wales 96 (108 men), Scotland 245 (251 men) It is pointed out in the Committee's note that the figures for 1929–30 are swollen by the admission of 232 students to two year courses of training as teachers at university colleges, at the special request of the Board of Education, in view of the projected raising of the school age

London has increased its lead as the university having the greatest number of full time students (9141) The next twelve in order, Cambridge, Glasgow, Oxford, Edinburgh, Wales, Manchester, Liverpool, Durham, Leeds, Birmingham, Aberdeen, Bristol, show no change in their relative positions in this respect All universities except Aberdeen and Reading show some increase

The number of full time students from homes outside the British Isles was 4573, being 10 per cent of the total and 4 per cent more than in the preceding year More than one third of these are from foreign countries, and the number of such foreign students tends to increase somewhat rapidly It increased by 26 per cent in the five years 1923–29, and by 9 per cent from 1928–29 to 1929–30 The corresponding increases in the numbers of students from countries in the British Empire beyond the British Isles were 14 per cent in the five years 1923–29 and only 1 3 per cent in the following year Why the pull of the home universities is waning in these countries while waxing in foreign countries is a question on which light could perhaps be thrown by the delegates who are to meet at Edinburgh in July in the fourth Congress of the Universities of the Empire The universities which have the largest numbers of students from countries within the Empire outside the British Isles are London (1060), Edinburgh (456), Cambridge (352), Oxford (296), Glasgow (177), and Manchester (79) In addition to full time students, there were 653 part time students whose homes were outside the British Isles but within the Empire, and 852 foreign part-time students

The distribution of the full time students among the various subject groups in 1929–30 was arts, 53 4 per cent, medicine, 19 1, pure science, 16 5, technology, 9 1, agriculture, 1 9 This shows but little variation from the preceding year's distribution The decline in the number of men medical students, which had been continuous since 1923 24, was arrested in 1928 29, when there was an increase of 205, which was followed by a further increase in 1929–30 of 310 The similar decline in the number of women medical students continued down to 1929–30, when there was a small increase, from 1108 to 1136

Full time advanced students numbered 2128, of whom 1763 were men, an increase of 46 (men 55) The greater number of these students were at work at Cambridge (355), University College, London (228), Imperial College of Science, London (227), King's College, London (123), London School of Economics (121), Oxford (172), and Edinburgh (133) Their distribution among the various subject groups was as follows mathematics and pure science, 42 4 per cent, arts, 39 2 per cent (35 per cent of the men and 58 per cent of the women), technology, 11 5 per cent, medicine, 4 7 per cent, agriculture, 2 2 per cent Chemistry, including applied chemistry and biochemistry, claimed 487 students, engineering 216, physics 140, botany 87 In addition to these full time students, 1683 part time students (1351 men and 332 women) were engaged in advanced work

A table showing the numbers of full time staffs employed in the teaching departments gives the following totals professors, 798, readers, assistant professors, and independent lecturers, 334, lecturers, 1147, assistant lecturers and demonstrators, 827, and others, 243 The number of lecturers is somewhat understated owing to the Oxford and Cambridge returns excluding lecturers holding no full time university appointment, many of whom actually devote their whole time to teaching Omitting Oxford and Cambridge, the table shows that for the instruction of every hundred full time students there were available, on an average, the following full time teachers professors, 2, readers, etc, 0 9, lecturers, 3 3, assistant lecturers and demonstrators, 2 1, and other teachers, 0 7—total, 9 Taking England alone, exclusive of Oxford and Cambridge, the ratio of full time teaching staff to full time students was 10 8 per cent, in London alone it was 9, in Wales 11, and in Scotland 5 7

Statements of income and expenditure show totals of £5,338,064 and £5,280,530 respectively Commenting on these accounts, the Committee observes that of the fifty two institutions included in the returns, only two or three show deficits representing any serious financial weakness

Second International Congress of the History of Science and Technology

MEN of science from all parts of the world who are interested in the history and evolution of their subjects will be meeting at the Second International Congress of the History of Science and Technology to be held in London on June 29–July 4 under the presidency of Dr Charles Singer The Congress is held under the auspices of the Comité International d'Histoire des Sciences, with the collaboration of the Comité International des Sciences Historiques, the Newcomen Society for the Study of the History of Engineering and Technology and the History of Science Society Inquiries concerning membership and meetings of the Congress should be addressed to one of the honorary secretaries, Mr H W Dickinson, or Mr Walter Adams, The Science Museum, South Kensington

The Government is showing great interest in the Congress The President of the Board of Education,

the Right Hon H B Lees Smith, will open the proceedings at the inaugural meeting on Monday, June 29, the Director of the Science Museum, Sir Henry Lyons has generously invited the Congress to make the Science Museum its headquarters throughout the week, and other Government departments, such as the Royal Botanic Gardens, Kew, the Royal Observatory, Greenwich, and the Natural History Museum, have offered hospitality to members of the Congress

Three vexed problems in scientific method will occupy the attention of members at the morning sessions on Tuesday, June 30, Thursday, July 2, and Friday, July 3 The first discussion will have as its general theme, "The Sciences as an Integral Part of General Historical Study" Prof Gino Loria of Genoa, will take the chair at this meeting Mr G N Clark, of Oxford, late editor of the *English Historical Review*, will open the discussion Among those who will take part are Profs A V Hill and A F Heath and Dr Dampier Whetham On the same morning a discussion will be held on the teaching of the history of science Prof Welch of Johns Hopkins University, will take the chair, and contributions have been promised from Profs Loria, Wolf, and Aldo Mieli, of Paris

The discussion on July 2 will be on the "Historical and Contemporary Inter relationship of the Physical and Biological Sciences" Prof William Ritter, of California, will take the chair, and opening papers have been promised by Prof J S Haldane, of Oxford, and Prof W H Welch, of Johns Hopkins Prof Baas Becking, of Leyden, Dr Joseph Needham, and Prof Lancelot Hogben will be among the speakers The final discussion (July 3) will be upon the "Inter dependence of Pure and Applied Science" Sir Henry Lyons will occupy the chair, and contributions are promised from Sir Napier Shaw, Profs F G Donnan and C H Desch Mr R V Vernon, of the Colonial Office and others

The United States will be well represented by delegates from the following institutions, among others Columbia University, Brown University, Providence, Yale University Rochester University, Bryn Mawr College, Colorado University, Clark University, Worcester, Smith College, Northampton Georgetown University, Boston University, Dartmouth College, Hanover, Michigan University, University of California, Bates College, Lewiston Pomona College, Claremont, Duke University, Durham, University of Cincinnati, State University of New Jersey, New York University, Massachusetts Institute of Technology, Goucher College Baltimore, Utah State Agricultural College, University of Minnesota, Haverford College, Ohio State University, Mount Holyoke College, The Harvard Railway and Locomotive Historical Society

Of other universities outside the British Isles, representatives have been appointed from Alberta, the Muslim University of Aligarh, Allahabad, Basel Berlin, Bombay, the Université libre of Brussels Calcutta, Cape Town, Dacca, Guatemala, Hamburg Hong Kong, Leyden, Lucknow, Università Cattolica of Milan, Montevideo, Madras, New Zealand, Nova Scotia, Oslo, Punjab Rangoon, Stellenbosch, Toronto, Tasmania, and a number of others Among other institutions that will be represented are the Gesellschaft fur die Geschichte der Naturwissenschaften of Berlin, the Institut fur Geschichte der Medizin und Naturwissenschaften of Leipzig, and the Kulturwissenschaftliche Bibliothek Warburg of Hamburg The Academy of Material Culture of Leningrad expects to send three representatives

A full programme has been arranged for the social entertainment of members and guests Receptions are to be given by the Royal Society, the Royal Society of Medicine, the Royal Institution, and the Institute of Historical Research Special excursions are to be made to the Universities of Oxford and Cambridge, which have offered hospitality to members of the Congress The Provost of University College London, will entertain members at an Independence Day luncheon on July 4 Special visits will be made to the Royal Botanic Gardens, Kew, the Royal Observatory, Greenwich, Barbers' Hall, and the Royal College of Physicians

A Ladies Committee, under the chairmanship of Mrs T F Tout, is arranging a programme of visits for ladies at the Congress who will not be attending the morning sessions

Water Power Developments in the United States

RETURNS which have recently been issued by the Geological Survey of the United States Department of the Interior (*Report* No 50,669) afford some interesting particulars of recent developments in the utilisation of the water power resources of the country Up to Jan 1, 1931 the total capacity of water wheels installed in water power plants of 100 horse power or more was nearly fifteen million (14,884,667) horse power, representing an increase of more than a million (1,076,889) horse power, or 7 2 per cent, during the year 1930 In an article in NATURE for April 18, the corresponding figures for Canada were shown to be 6,125,000 horse power and 397,850 horse power An estimate based on present practice in the installation of plant for the utilisation of water power indicates that about nineteen per cent of the available resources in the United States have been exploited, as compared with about fourteen per cent in Canada

This estimate, however, as also that in the case of Canada, though taking into account the results of the latest surveys and investigations, cannot be regarded as final In a number of the States, more particularly those in the south and centre, additional information is required before a definitely reliable figure can be arrived at A moiety of the available power of the Niagara River and of the international section of the St Lawrence River is included, though it is pointed out that an international agreement will be necessary in order to permit of the full development of these supplies

Washington comes first among the individual States in extent of potential supplies, and is followed fairly closely by California, Oregon, and New York A large proportion of the potential resources of the last named State is available continuously, as distinguished from the bulk of the supplies elsewhere, which are of an intermittent character This is due to the equalisation of the flow of the Niagara and St Lawrence Rivers The same remark applies to the States of Arizona and Nevada, where the resources are mainly on the Colorado River, the flow of which can be controlled

The 14,884,667 horse power realised to date in the whole of the Union is the product of 3344 individual installations of which nearly one half (1588), with a capacity of 13,108,830 horse power, are public utility and municipal undertakings, the remainder being devoted to manufacturing and miscellaneous purposes

Association of Teachers in Technical Institutions

THE twenty second annual conference of the Association of Teachers in Technical Institutions was held at Manchester during the Whitsuntide holiday On Whit Monday the Association was accorded an official welcome by Alderman F J West (ex-Lord Mayor of Manchester and a member of the Government Committee on Education for the Engineering Industry), Dr Stanley Hodgson (Chairman of Governors, Royal Technical College, Salford), and Alderman J Smith (Chairman of the Bury Education Committee) On the same day the retiring president, Mr H A Norman (of Bury), inducted the president for the coming year, Mr H Ade Clark, who delivered his presidential address

Those who expected Mr Clark to deal with the matter of salaries (notice has been given that the present scales of salary for technical teachers will be terminated on Mar 31, 1932) were disappointed He insisted that the question was one for the Association's representatives on the Burnham (Technical) Committee, and said that whatever the outcome of negotiations might be, the Association could not lose sight of the problems which it had to face in company with the Board of Education, the local education authorities, and those engaged in the country's industry and trade Those problems, he said, had been well summed up by one of his predecessors in office Mr A E Evans, in a paper to the last North of England Education Conference ' Soon after the War it became apparent that, hitherto unchallenged, or feebly challenged, commercial and industrial supremacy of Britain was likely to experience a fierce onslaught from other nations It was recognised by those engaged in our technical institutions that one of the weapons of defence would be a system of education which would provide men and women – whether as leaders or as led—who realised the potentialities of this country and its associated Commonwealth as one of the great manufacturing carrying, and exporting civilisations of to day To determine these potentialities and how best to educate men and women for their development was of vital importance "

With these points in mind Mr Clark surveyed the rapid developments of technical education, and, in indicating the Association's work in connexion therewith, he showed that it was not in Britain alone that the work of technical education was becoming recognised The Association was in touch with the Technical Instructors' Society of Australia, it was linked to the great American continent through the English Speaking Union its views had been sought and given to the World Conference of Education Associations at the Geneva meeting, and its representatives had formed part of the English delegation which attended last summer, the International Congress on Technical Education held at Liege under the auspices of the Belgian Government, when twenty two nations were represented

In spite of this development of national and international opinion, however, Mr Clark indicated the difficulties which technical education had still to face If a scientific approach were to be made towards the solution of our problems of education and industry, it was clear that a small national co ordinating committee would be necessary to bring together the information secured by local bodies which were forming machinery to draw together educationists and industrialists The Board of Education was not yet prepared to admit the necessity of such a committee

Frequently too, those responsible for local educational administration seemed, "like the tradition loving schoolmaster, unable to view problems except through academic spectacles They fear to face the implications of the changing needs of the kaleidoscopic industrial and commercial civilisation in which we live It rationalisation means the application of organised knowledge, the importance of technical education has to be realised by educationists as well as industrialists The latter are by no means the only people clinging to ancient methods and conceptions "

To show that those who may be powers in public life also needed convincing, Mr Clark referred to a recent speech of the Right Hon Sir Herbert Samuel M P, who said (as though to show the superiority of university to technical education) that although technical colleges may be useful and necessary non technical institutions gave something better Men, he said, are not content with obtaining the means of getting a living, they want to live, and the most powerful events of our time do not turn upon economic issues In such thinking, Mr Clark suggested, there is a lack of clarity "Does not a university provide technical education? What sort of doctors lawyers architects, would we have if it did not? And do technical colleges not teach the art of living? Is there any better way that such an art can be taught than by the relationships of men (social industrial and commercial) made through the work they have to perform in the world? Where would our art of living be without our engineering our chemistry our building, and our domestic science? And is there any art or ideal or joy that is not ultimately dependent on economic issues?"

Among the resolutions dealt with by the Conference was one asking for a review of the conditions of entry into various branches of industry It stressed the desirability of remission of some period of apprenticeship for ex full time pupils of senior and junior technical schools, the need for an extended provision of opportunity for all entrants into industry to pass into the ranks of skilled workers and the need for further provision of part time day courses for apprentices and learners Considerable discussion was also centred upon a resolution which included a declaration that a knowledge of biology is part of a sound general education, and that more experts are needed in biological subjects for the proper development of agriculture and industry

In connexion with the Conference an excellent exhibition of books and apparatus was provided by a number of publishers and apparatus manufacturers

Organisation of a Locust Campaign

THE locusts constitute one of the oldest known plagues of agriculture, but the efforts to study them have always been sporadic and local, while the problem is a very wide one It is very gratifying to learn, therefore, that the Empire Marketing Board, acting on the recommendations of the Committee on Locust Control of the Economic Advisory Council, has made a grant of £2720 towards the organisation of exhaustive investigations on locusts The grant represents one half of the estimated cost of investigations during the first year, the other half being covered by contributions from the various British territories participating in the scheme

The investigations are being conducted by the

Imperial Institute of Entomology, where a special section has been formed for the collection and summarising of all the available information on locusts Regular reports on the appearance and movements of locusts are being received in the Institute, where they are analysed and correlated so that a clear picture of the situation is obtained and deductions can be drawn as to the possible source of each invasion Data of this kind make it possible to draw conclusions as to which areas can be suspected as the probable permanent breeding grounds of locusts

At present the Red Sea littoral of Africa, the northern provinces of Kenya, and certain areas in Arabia are marked down as deserving a close investigation, and two field entomologists will be sent shortly to the Sudan, and one to Kenya, to study the conditions on the spot It is hoped that the field entomologists will be able not only to locate the breeding areas but also to study the natural conditions which make them favourable for locust breeding Thus, the first year's programme of work consists mainly of a preliminary ecological survey of the breeding areas The whole scheme is planned to cover a period of five years, and it is proposed to establish a field laboratory for studying locust bionomics on the spot and for experimenting on natural factors which may be responsible for controlling locusts or encouraging their multiplication and the transformation into the swarming phase Knowledge of this kind would make it possible to suggest methods for preventing outbreaks or at least to forecast outbreaks, which alone would mean an enormous saving

The investigations were proposed originally to include only British territories, but lately certain foreign governments have expressed their readiness to co operate in the scheme Such a concerted attack on the locust problem has never been attempted before, and valuable results can confidently be expected

University and Educational Intelligence

CAMBRIDGE — The report of the General Board in connexion with the scheme for the employment of the Rockefeller Endowment for Scientific Departments recommends that the following posts be established as from Oct 1 a University lectureship in cytology in the Department of Agriculture a University lectureship in plant physiology and a University lectureship in mycology in the Department of Botany an additional University lectureship and an additional University demonstratorship in the Department of Biochemistry

In a series of reports the General Board recommends that readerships in the University should be created for the following Mr F T Brooks, of Emmanuel College, in mycology, Dr A D Imms, of Christ's College, in entomology, and Mr James Gray, of King's College, in experimental zoology The following posts will also be created a curatorship of the Sedgwick Museum in the Department of Geology, a senior curatorship and a junior curatorship of the Museum of Zoology

At Clare College, Dr H Godwin, research fellow of the College and University demonstrator in botany, has been appointed to an official fellowship At Trinity College the following have been elected to research scholarships J C Jaeger in mathematics, W G Thompson in physics, E F Warburg in botany, and P Ullyott in zoology

EDINBURGH Dr Walter Smith Kay, who died on April 22, has bequeathed to the University the sum of £5000, subject to Government duty, the annual income to be applied towards aiding research in mental diseases or psychiatry in such manner as the University Court and the professor of psychiatry shall think fit

The Senatus has intimated that Prof Sydney Smith is appointed dean of the Faculty of Medicine, in succession to Prof Lorrain Smith, who died on April 18

LONDON —Dr C R Harington (pathological chemistry) has had the title of professor conferred on him in respect of his post at University College Hospital Medical School, Mr James Fairgrieve (education, with special reference to methods of teaching geography) has been appointed reader in respect of the post held by him at the London Day Training College, and Dr R C J Howland (mathematics) has been appointed reader in respect of the post held by him at University College

The title of emeritus professor of experimental pathology in the University has been conferred on Sir Charles Martin, and that of emeritus professor of biochemistry in the University on Dr Arthur Harden on their retirement from the Lister Institute of Preventive Medicine

OXFORD — In view of certain statements in the Report of the Library Commission, by which it appears to be contemplated that the part of the Old Ashmolean Museum at present occupied by those engaged on the Oxford English Dictionary shall be "retained as a first provision for large co operative enterprises" such as the Dictionary of National Biography, the Association of Friends of the Old Ashmolean, at its annual meeting held on May 29, adopted a resolution strongly advocating the restoration of this historic building to scientific purposes akin to those for which it was originally founded At the same meeting it was pointed out that there is still a confusion in the minds of many persons as to the relations existing between the two museums known as the "Ashmolean" and "Old Ashmolean" respectively The Ashmolean Museum exists for the purpose of illustrating art and archæology, whereas the Old Ashmolean was intended for scientific studies, and has been intimately associated with the natural sciences ever since 1683

THE Scientific Club of Winnipeg has awarded its Research Prize of 250 dollars, for the most meritorious investigations conducted by a post graduate student in the University of Manitoba during the last three years, to Dr P A Macdonald The researches of Dr Macdonald, which were carried out in the Department of Physics, consisted of studies of the senses of temperature, pain, vision, touch, and hearing, with particular reference, in the last three, to the validity of the Weber Fechner law

A NUMBER of studentships in relation to cotton growing, not exceeding eight in all, will be awarded in June next by the Empire Cotton Growing Corporation They will be of two kinds, namely, specialist studentships and agricultural studentships The first named are intended to enable graduates, who believe that they have a leaning towards research, to equip themselves for posts in which work of that type is required Successful candidates will, in general, be required to take a course in agriculture during the tenure of their studentship if they do not possess an adequate knowledge of the subject The Agricultural Studentships are intended to enable men to receive such specialised instruction as their previous qualifications and experience show to be most desirable in order to equip them for agricultural posts in cotton growing countries wherever opportunities for employment may present themselves, whether in government agricultural departments, with commercial cotton growing companies, or under the Cotton Growing Corporation Forms of application, returnable by, at latest, June 10, can be obtained from the Secretary, Empire Cotton Growing Corporation, Millbank House, 2 Wood Street, S W 1

Birthdays and Research Centres.

une 7, 1877.—Prof. C. G. BARKLA, F.R.S., professor of natural philosophy in the University of Edinburgh.

The *J* phenomenon still engages our attention on account of its seemingly fundamental nature. Experimental results 'cut right across' current theory and indicate that some properties of radiation (at least) are controlled not by independent constituent wave trains or quanta but by a quality of the whole stream of radiation more closely allied to temperature. Some elusive condition is, however, essential to the occurrence of the *J*-discontinuities—a condition found to be independent of the nature and disposition of apparatus so far as these are externally observable. Recent experiments with Mr. Honeyman show the rapid development of the characteristic discontinuities with the time of exposure of the radiating substance to X-rays; while experiments with Mr. Kay confirm and extend this conclusion by showing that two different specimens of one kind of radiating substance behave differently at the same time, one providing discontinuities, the other not. Our immediate problem is to discover the nature of this critical state of the radiating substance.

June 11, 1867.—Prof. CH. FABRY, professor of physics in the University of Paris.

Nous connaissons assez bien la partie basse de notre atmosphère, celle qui nous est directement accessible. Mais au dessus, entre la basse atmosphère et les espaces cosmiques, s'étend une région étendue, qui fait encore partie de la terre puisqu'elle gravite avec elle, et dont l'étude est très difficile. Cette étude est cependant fort importante; ce sont ces hautes couches de notre atmosphère qui reçoivent tous les chocs venant de l'extérieur: Étoiles filantes et bolides, corpuscules électriques (rayons cathodiques et rayons positifs), radiations de toutes longueurs d'onde. Ce que l'on sait sur ces hautes couches a été trouvé un peu par hasard; c'est ainsi que l'étude pratiqué des communications par radio a fait connaître l'existence de hautes couches renfermant un nombre important de charges électriques.

L'étude de l'absorption des radiations venant des astres, en particulier du soleil, dans leur passage à travers notre atmosphère, a révélé aussi des choses très inattendues. Il y a, dans la partie haute de notre atmosphère, une certaine quantité d'ozone, qui absorbe une grande partie des radiations ultra-violettes venant du soleil. Des résultats fort importants ont déjà été obtenus, en particulier par Dobson et ses collaborateurs; l'étude demande à être poursuivie. Des recherches récentes (Buisson, Ladenburg et Götz) ont confirmé que la basse atmosphère contient un peu d'ozone; il faut en tenir compte dans les études sur l'absorption. L'altitude de la principale couche d'ozone de la haute atmosphère a été, jusqu'ici, évaluée à 50 km environ; si l'on tient compte de l'ozone de la basse atmosphère, on sera probablement amené à placer encore plus haut l'ozone de la haute atmosphère, peut être à 80-100 km (Chalonge). Cet ozone est peut être en relation avec la couche ionisée que révèlent les observations sur la radio.

Les expériences récentes poursuivies dans divers pays sur les *fusées* donnent l'espoir que l'on pourra un jour envoyer des instruments dans ces très hautes régions.

Societies and Academies.

LONDON

Royal Meteorological Society, May 20.—Sir Gilbert Walker: Recent work by S. Mal on the forms of stratified clouds. Two years ago it had been suggested that the breaking up of a stratum of cloud into polygons or long strips was often due to instability, accompanied in the latter case by shear parallel to the strips. Mal showed that a rectangular pattern was caused when the unstable stratum was subjected to a less rapid shear than is needed for strips; and verified from measurements made in the sky that cloud strata break up or persist according as their temperature gradient is unstable or stable; and that when they break up the pattern assumed is polygonal, rectangular, or in strips according as the shear is zero, moderate, or large.—**C. K. M. Douglas**: A problem of the general circulation. So far as can be judged from present data, there is no appreciable net flow of polar air in the lower troposphere towards the subtropical anticyclone. This supports the view of Dr. Jeffreys, namely, that the exchange of air between different latitudes, required to maintain the angular momentum of the zone of west winds against friction, is carried out entirely by currents lying side by side, and not one above the other. The fundamental problem is the relation of the individual cyclone to the general circulation, and this has not yet been solved.—**G. S. P. Heywood**: Wind structure near the ground, and its relation to temperature gradient. The wind velocities were obtained by two anemometers at heights of 12·7 m. and 94·5 m. above the ground. There are not many results from anemometers so high as 95 m.; for this reason, the ordinary diurnal variation at this height in summer and winter is shown, with that at 13 m. for comparison. The vertical gradient of temperature up to 87 m. is also recorded. Wind gradient must depend largely on temperature gradient, and the relation between the difference in wind velocity and the difference in temperature over approximately the same height interval, is worked out for various wind strengths.

PARIS

Academy of Sciences, April 20.—The president announced the death of René Kœhler, *Correspondant* for the section of anatomy and zoology.—**M. Delépine**: Notice on Raffaello Nasini.—**L. Joubin**: Notice on René Kœhler.—**Lucien Daniel**: The persistence and accentuation of variations in the descendants of the Jerusalem artichoke grafted on the sunflower. In agreement with the hypotheses of Lamarck and Darwin, it has been proved by a series of experiments started in 1894 that grafting in the Jerusalem artichoke and its descendants is a powerful factor of variation, the action of which persists and is sometimes accentuated in the successive generations of this species.—**W. Tartakowsky**: The representation of a system of numbers by a system of positive additive quadratic forms.—**S. Carrus**: The integration, without the sign of quadrature, of certain systems of differential equations with any coefficients.—**Mlle. Marie Charpentier**: Semi-closed ensembles and their applications in the theory of Peano points.—**E. Kogbetliantz**: Jacobi developments.—**N. Abramesco**: The movement of a variable plane figure with conservation of similitude.—**Alfred Rosenblatt**: The plane movements of viscous liquids adjoining radial movements.—**Paul Woog, Mlle. Emilie Ganster,** and **Jean Givaudon**: The stabilisation of oils for chronometry. Fatty oils as lubricants for clocks and watches have advantages over mineral oils, but have the dis-

advantage that the viscosity changes owing to oxidation Experiments on various anti oxygens, based on the work of Moureu and Dufraisse, have led the authors to propose a mixture of β naphthol and a red dyestuff to be added to the oil The former prevents oxidation, and the dye by absorbing the actinic rays hinders oxidation due to exposure to daylight — **G A Mokrzycki** Determination of the combustible necessary to reach the practical plafond — **G Reboul** Singularities presented by bodies submitted to the action of resistance cells **Th V Ionescu** Ionised gases and Coulomb's law The existence of a vibration period for ionised gases makes possible the calculation of the velocity of propagation of an electric wave in these media —**Mlle Paule Collet** and **G Foex** The magnetic states of platinum —**V Lalan** The hypothesis of the curve of pursuit and refraction in optical systems in motion —**H Hulubei** and **Mlle Y Cauchois** A simple and luminous arrangement for the study of the Raman effect —**Jean Becquerel** and **Louis Matout** A new magneto optical effect rotatory power along the optical axis of certain uniaxial crystals in the neighbourhood of absorption bands under the action of a magnetic field normal to this axis —**S Rosenblum** and **M Valladares** Figures of distribution of the active deposit on electrodes — **Georges Fournier** The existence of different isotopes A list is given of probable isotopes not so far found experimentally —**René Pallu** The decomposition of monobarium phosphate in solution — **Georges Arditti** The oxidation of paraffin oil by air For the detection of the first traces of acid formed by the oxidation, use is made of Dubrisay's method of the change in the interfacial tension between the oil and a solution of caustic soda At temperatures of 15 C and 85 C there is no oxidation, but traces of acid appear at 110 C —**P Bary** and **E Fleurent** The law of degradation of solutions of rubber as a function of the time at different temperatures —**P Laffitte** and **M Patry** The transmission of a detonation at a distance **M Paic** The double compounds between the mercuric sulphates and mercuric iodide **J Bougault** and **G Schuster** A new triglyceride obtained from cocoa butter A palmitostearoazelain —**M Tiffeneau, Mlle Jeanne Lévy,** and **E Ditz** Two diastereoisomeric derivatives of campholenic acid their formation in unequal but inverse proportions by inverting the order of introduction of the fixed radicals — **R Cornubert** An attempt at the reproduction of a tetrahydropyrone compound —**Charles Dufraisse** and **Roger Netter** Researches on the ethylenic ketones α bromo β aminobenzalacetophenones —**Marcel Godchot** and **Mlle Germaine Cauquil** Some new derivatives of the cyclo octane series A new cyclo octene oxide is described, as well as the glycol obtained by its hydration — **R Paul** The action of magnesium on some halogen substituted ether oxides The reaction between magnesium and oxides of the type $RO(CH_2)_3X$ ($X = I$, Br, or Cl) has been studied The reaction is influenced both by the catalyst added and by the nature of the solvent —**Paul Gaubert** The artificial coloration of crystals of oxalate and nitrate of urea A study of the influence of various colouring matters on the crystalline forms of urea oxalate and urea nitrate —**F Zambonini** and **V Caglioti** New researches on the chemical composition of sarcolite from Mont Somma (Vesuvius) Five complete analyses are given these are not in agreement with the formula proposed by Gossner and Mussgnug —**Yang Kieh** The dislocated zone situated to the north of the Chaîne de la Marche **V Frolow** The periodicities of the risings of the Niger at Koulikoro The results of the study by the method of A Wallen of 24 years' data —**R Bureau** The variations of wireless atmospherics during the eclipse of the moon of April 2, 1931 The curves of the records of atmospherics recorded at Saint Cyr and at Mont Valérien show a marked anomaly between 18 h and 24 h on April 2, 1931 Hence there is a connexion between the eclipse of the moon and atmospherics —**Jean Chevrier** Magnetic exploration in Syria —**P L Mercanton** The inversion of the magnetic inclination in geological time New observations In an earlier communication, a study of the natural magnetisation of volcanic lavas of various origins (Greenland, Spitsbergen, Australia) led to the conclusion that at the Tertiary epoch, at the time of the great volcanic outbursts, the terrestrial magnetic inclination was, in both hemispheres, the reverse of what it is to day Further experimental data in support of this view are now given —**F Labrousse** The changes in reaction observed in the course of the development of some fungi The influence of the nature of the nitrogenous food material —**E Wollman** and **V Uribe** Researches on humoral immunity in cold blooded animals —**Maurice Nicloux** The micro estimation of organic substances in dilute solutions by sulphochromic oxidation Special application to the micro estimation of ethyl alcohol —**Delherm** and **Laquerrière** A new apparatus for faradic currents

ROME

Royal National Academy of the Lincei, Nov 2 —**F Vercelli** Complementary observations to the note on a general method for the analysis of the periodicity in statistical and experimental diagrams **C Carathéodory** Canonical transformations of slipping and their application to geometrical optics —**R Nasini** Discovery of boric acid in the glaze of the vases of Arezzo The glaze of these vessels, which constitute one of the finest examples of the Roman art of the first century B C and the first A D contains boric acid, not in accidental traces, but as a definite component (see NATURE, Dec 6, p 877) —**S Amante** Matrices which satisfy a given algebraic equation —**B de Finetti** Determinate and indeterminate problems in the calculus of probabilities —**Maria Pastori** Isotropic tensors relation between the components **Margherita Piazzolla-Beloch** Connected oblique multilaterals —**E Čech** A demonstration of Jordan's theorem **A Kolmogoroff** The conception of the mean —**Nikola Obrechkoff** A generalisation of Cesàro's summation —**G Rabaté** Some points of direct infinitesimal geometry Investigations on the notions of contingent and paratingent used by G Bouligand as instruments of his direct infinitesimal geometry are summarised — **E Gugino** The extension of Morera's theorem to the motion of systems with reversible linkings —**L Poggi** Extension of D'Alembert's paradox and of the Kutta Joukowski theorem to circular arc profiles —**E Pistolesi** The dynamic actions of a circulatory current on cusped profiles —**A Signorini** The mechanics of continuous systems In dealing with any problem of finite deformations, it is convenient, in the first place, to subject the general equations of the mechanics of continuous systems to a transformation analogous to that which, in the particular case of hydrodynamics, leads from Euler's equations to those of Lagrange A new Lagrangian form of the indefinite equations now given may be of use in the indirect solution of certain particular problems —**Angelina Cabras** The mechanics of rigid bodies in generalised spaces A scheme of procedure for applying the methods described in a preceding note to the static and dynamic treatments to all elliptical S_n is given —**Enrico Volterra** The general laws of the vibrations

of a network of stretched elastic wires with nodes in common and fixed or vibrating extremities are considered, the initial configuration of the system and the initial velocities of the elements of the elastic elements of the system being assumed known The application of such laws to the study of water hammer in a network of pipes under pressure is described — **R Bilancini** The coefficient of correlation An examination is made of the coefficient of correlation in the case when the relation between the two magnitudes considered is not linear, but when one of the magnitudes is expressible by means of a polynomial of the other of degree n, greater than one **E Fermi** Quantistic electrodynamics (2) The quantistic forms recently derived for the equations of a system composed of an electromagnetic field and of any number of point electric charges referred to the non relativistic case the velocity of the charges being not very high These are now converted into the relativistic forms by a method other than that based on Dirac's theory of the rotating electron — **G B Pacella** Simple method for the calculation of an aspherical plano convex lens The form to be assigned to an aspherical lens with one plane face in order that it may be stigmatic for the point on the axis at infinity when a beam of monochromatic light falls on it is determined **A Masotti** Calculation of the resultant and of the resultant moment of the electrostatic pressures in a plane field by formulæ analogous to the hydrodynamical formulæ of Blasius The analogy between the electrostatic pressures exerted on the surface of an electrified conductor in equilibrium and the hydrodynamic pressures of a liquid in permanent irrotational motion on the surface of an immersed solid, is developed It is shown that for an indefinite cylindrical conductor in an electric field with distribution uniform to infinity the resultant of the electrostatic pressures on unit length of the conductor has the direction and sense of the electric force at infinity, while its magnitude is the product of such force by the charge of unit length of the conductor ; the system of electrostatic pressures is equivalent to the resultant applied at the barycentre of the charges —**A Corbellini** and **L Barbaro** The anomalous decomposition of the tetrazo derivative of 2 2 diamino 1 1′ dinaphthyl The acid melting at 250 252 , previously observed is a product of this decomposition, is formed by partial decomposition of the tetrazo compound when acid solutions of its sulphate or chloride are heated This reaction proceeds also, although very slowly, at the ordinary temperature, and yields in addition, neutral compounds difficult to purify - **Morello Morelli** Spectrochemistry of solutions of boric acid in glycerin The molecular and specific refractivities of boric acid in glycerin solution are greater than in aqueous solution, and decrease as the concentration of the solution is increased Dissolution of boric acid in glycerin is accompanied by expansion, the extent of which increases markedly with the concentration — **F Rodolico** Polyhedric pisolites of magnesite and of dolomite - **G Mezzadroli** and **E Vareton** Action of ultra short electromagnetic waves ($\lambda = 2\ 3$ m) on silkworms (3) Irradiation of the eggs The favourable effect of the waves is increased if the exposure is commenced prior to hatching of the eggs —**M Fedele** Innervation and peripheral sensitive arrangements of the arterial trunk of reptiles **S Ranzi** Conditions determining the development of gills (investigations on the experimental embryology of cephalopods) —**M Mitolo** Oxygen and central nervous functions One of the mechanisms which explain the action of oxygen in the functions of the central nervous system and the indispensability of this gas to the central nervous elements is the continuous oxidation of acids occurring among the metabolic products of this system **Clara Forti** Excision of the vessels and nerves of the ovary, total or partial excision and metabolism (3) This excision produces slight retardation of the metabolism during the first few months after the operation

ELECTROPLATERS AND DEPOSITORS TECHNICAL SOCIETY (at Northampton Polytechnic Institute), at 8 15 —W T Griffiths Continental and American Practice in Nickel Deposition

ROYAL SOCIETY OF MEDICINE (Surgery Section) (Annual Meeting) (at Manchester Royal Infirmary).

THURSDAY, JUNE 11

ROYAL SOCIETY, at 4 30 —M L E Oliphant Electron Emission from Langmuir Probes and from the Cathode of the Glow Discharge through Gases —H E Watson, G Gundu Rao and K L Ramaswamy The Dielectric Coefficients of Gases Part I —G D Bengough, A. R. Lee and F Wormell The Theory of Metallic Corrosion IV

OPTICAL SOCIETY (at Imperial College of Science and Technology), at 8 —Sir John H Parsons Young s Theory of Colour Vision (Thomas Young Oration).

FRIDAY, JUNE 12

ROYAL ASTRONOMICAL SOCIETY, at 5 —Dr L J Comrie Note on Mr Chappell s Method of Second Difference Integration —Bertha Swirles The Absorption Coefficient of a Degenerate Gas —G Castelnuovo De Sitter s Universe and the Motion of Nebulæ

ROYAL SOCIETY OF MEDICINE (Ophthalmology Section), at 5 —Annual General Meeting

MALACOLOGICAL SOCIETY OF LONDON (at Linnean Society), at 6

ROYAL INSTITUTION OF GREAT BRITAIN, at 9 —Dr C L Woolley Latest Excavations at Ur

PUBLIC LECTURES.

FRIDAY, JUNE 5

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE (Public Health Division), at 5 —R R Hyde Industrial Welfare.

TUESDAY, JUNE 9

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE (Public Health Division) at 5 —Sir George Buchanan International Hygiene

INSTITUTE OF PATHOLOGY AND RESEARCH (St Mary s Hospital W 2), at 5 —Prof J S Haldane The Problems of Silicosis

WEDNESDAY, JUNE 10

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE (Public Health Division), at 5 —A T Pike Town Planning.

FRIDAY, JUNE 12

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE (Public Health Division), at 5 —Sir Thomas Legge Industrial Poisonings

CONFERENCES.

JUNE 9 TO 12

INSTITUTE OF BRITISH FOUNDRYMEN (at Birmingham).

Wednesday June 10 (*morning*) (at Grand Hotel).—A Harley Presidential Address.

C W Spring The Effect of Elevated Temperatures on Grey Iron Castings

Prof H Thyssen Factors in the Conductivity of Irons

M Arzens The Laboratory and the Foundry

E N Simons The Merchandising of Castings

Dr J G A Skerl Sands and Sand Testing

J Arnott Silicon as an Alloying Element

W C Devereux High Duty Light Alloys

Thursday June 11 (at Coventry).—L H Pomeroy The Relationship between the Engineering and the Foundry Trades

J G Pearce Recent Developments in Cast Iron in Great Britain.

JUNE 10 TO 13

SOUTH EASTERN UNION OF SCIENTIFIC SOCIETIES (at Winchester).

Wednesday, June 10 at 8.—Sir J Arthur Thomson Some Natural History Problems of the Countryside (Presidential Address).

Thursday, June 11 (Botanical Section), at 11 A M —J Groves Stone worts, Ancient and Modern

At 11 45 A M —Prof S Mangham Plants as Civil Engineers.

(Archæological Section), at 11 A M —Dr W E St L Finny The Kings of Wessex from Egbert to Athelstan

At 12 45 —The late A Hadrian Allcroft The Pre History of the Village Church Part 2

Friday, June 12 (Geological Section), at 10 30 A.M —Prof H L Hawkins Some Generalisations on the Nature, Deposition, and Palæonto-logical Implications of the Chalk

At 11 45 A M.—F H Edmunds The Relation of Soil and Geology of the Weald

(Zoological Section), at 10 30 A M —J F Marshall The Stereoscopic Photomicrographs of Fossil Insects exhibited in the Congress Museum

At 11 A M —H. Main Insect Observations Underground

At 12 —E A Martin The Making of Pearls.

At 8 P M —W P D Stebbing A Motor Tour of 7500 miles from the Transvaal to Western Uganda (Public Lecture).

Saturday June 13 (Regional Survey Section), at 11 A M —H J E Peake Archæological Surveys.

SUMMER MEETING.

JUNE 11 TO 13.

NEWCOMEN SOCIETY FOR THE STUDY OF THE HISTORY OF ENGINEERING AND TECHNOLOGY (at Sheffield).

SATURDAY, JUNE 13, 1931.

Education for the Engineering Industry.*

THE triumphs of engineering science and technique are reflected by every development of modern civilisation, and further development will depend, to a large extent, upon the continued supply of qualified and capable engineers Here, then, is constituted a need which must be provided by engineers and educationists of to-day It depends on them whether the engineers of the next generation shall be trained and educated in a manner suited to the importance of their calling

The import of this has been realised in some quarters for a considerable time In 1928 the Engineering and Education Sections of the British Association held a joint discussion upon "School, University, and Practical Training in the Education of the Engineer" Later in the same year, the President of the Board of Education appointed a Committee to inquire into technical education for the engineering industry The detailed and thorough nature of this investigation is shown by the Committee's report, which has been recently published by H M Stationery Office under the title "Education for the Engineering Industry"

In effect, this report is the expression of a general consensus of industrial opinion, and as such deserves careful consideration The tendency to direct attention to the practical or works executive side, almost to the exclusion of the office or administrative side, should be noticed Also, in accordance with the Committee's terms of reference, the report is, in the main, a review, interspersed with many valuable suggestions, but with no definite schemes for the amelioration of the evils noted To those interested in the subject, this last fact must cause real disappointment, for one cannot but feel that, if the duty had fallen within the scope of such a strong committee, some decisive and practicable schemes would have resulted Such recommendations would have received widespread and most careful attention

Considerable emphasis is brought to bear upon the subject of recruitment, and it might be well to review the sources of supply as reported About ninety per cent of the recruits come to the industry straight from the elementary school at the age of fourteen years, of the remainder, the majority probably come from junior technical schools at ages ranging from fifteen to sixteen years, while a smaller

* Education for the Engineering Industry 1 Report of the Committee on Education for the Engineering Industry, 2 Comments on the Report by Education Bodies Pp vii+67 (London H M Stationery Office, 1931) 1s 3d net.

proportion are recruited from secondary schools at ages from sixteen to seventeen years This neglects the comparatively small number received from universities and technical colleges

From the report, it would appear that, in general, recruitment is still carried out in a fashion quite haphazard, with little or no discrimination between the various types cited This alone renders the problem of subsequent training most difficult for all but very large industrial concerns, since no clearly defined regulations exist to guide individual firms Surely, as was suggested at the British Association in 1928, a standard national scheme of apprenticeship could be set up—a scheme which would be readily adaptable to suit the distinguishing features of at least the three main grades of recruits This is vitally an industrial concern, and that such an obvious opportunity should have passed unheeded forms a fit subject for regret

Industrial opinions on the merits of the three types of recruit are interesting The elementary school type is labelled satisfactory, with the caution that intelligent selection, preferably from central schools, is advisable, the junior technical school type would appear to have found unqualified approval, and recruitment from secondary schools is considered intrinsically sound Regarded as types, the first evidently finds least favour, but as the other two sources of supply cannot hope to cope with the demand, the problem of improving the general personnel of the engineering industry must centre in the betterment of the elementary school type This is in itself a task At the outset it must be realised that the majority of this section are not likely to profit by any serious degree of technical education Their subsequent learning, then, must consist almost entirely of purely descriptive work, with the aim of improving their ideas of the industry in particular and their outlook upon life in general The progress made during this course of descriptive work would readily indicate the minority capable of further advancement These remarks may, to a large extent, apply also to the junior technical school type of recruit The explanation of the favour bestowed upon this class may well lie in the fact that, in effect, these boys are highly selected the slight vocational bias in their training, even if it has no lasting effect, will certainly facilitate proper selection

The secondary school boy falls into quite a different category He is usually the pick of the elementary school type, advanced by a few years of higher education, and generally capable of assimilating a fair degree of technical instruction Unfortunately, in the report, he is all but maligned for showing a distinct preference for so-called 'black-coated' positions Assuming this to mean a preference for the office and, ultimately, the administrative side, is it not a quite natural tendency? Surely a certain incompatibility exists between higher education and manual labour A good grounding on the practical side is undoubtedly necessary for those aspiring to administrative posts, and apprentices with this aim in view will not object to gain their experience in the workshops On the other hand, perhaps the most progressive suggestion of all in this report concerns this class of recruit It is proposed that the period spent at school between the normal age of entry to apprenticeship and actual entry should be treated as part of the apprenticeship period It is also of interest to note that vocational training in secondary schools is not advocated, this conforms to general academic opinion

Regret is expressed at the divorce of men with high technical qualifications from the practical side of the engineering industry Such a situation is, however, not surprising if the note appended to the report by one of the members of the Committee is a true indication of the feelings of employers He states that he does not think that the average employer in general engineering works of Great Britain would be likely to train university students and afterwards offer them positions in productive departments No reasons are given Is this further evidence of the persistence of that old reluctance of the industrialists to admit the need for technical training? It is surely fundamentally right that the higher posts in industry should be filled by well-trained men How one can hope to become highly trained in these days without attending the university or technical college is difficult to understand

Finally, the admirable part of the report is that in which concerted action between industry and college, extension of part-time education, active encouragement for the boy with ability, and rational methods of promotion are all enthusiastically recommended Here we have evidence that these subjects are at last receiving sincere attention It is, however, unfortunate that no schemes are drawn up to show how these desirable objectives may be reached It can only be hoped that these recommendations will receive the immediate attention of all to whom they are directed Here the valuable suggestions appended to the report by Mr A E Berriman might well serve as guidance for a definite line of attack

MANY consider mathematics to be the most abstract and inhuman of the sciences, but to the connoisseur a mathematical treatise is a work of art, revealing by its style the temperament, aspirations, and even the human weaknesses of its author When we consider a collection of French books on pure and applied mathematics, we are reminded of the great differences between French and English ideals The clarity of the French style is well known and "what is not clear is not French" It was also a Frenchman who said that "language was given to us in order that we might conceal our thoughts", but this maxim appears to have influenced German and, to a lesser degree, English writers more than his own countrymen

Closely allied to clarity is the importance attached to logical precision In the training of French engineers at l'École polytechnique, for example, the course in elasticity will be a closely reasoned mathematical investigation, in which a logical flaw would be regarded as a scandal When their studies are complete, the young engineers will go out into the world and discover with amazement that the problems of actual machines are not always amenable to such refined methods In some cases they will adapt themselves to practical requirements, but in others they may feel a lasting prejudice against practical work and never really settle down to the real requirements of their profession In England, on the other hand, the tendency is to emphasise the practical aspect at the expense of the underlying theory This has the disadvantage that persons so trained may not have sufficient grasp of fundamental principles, in spite of their knowledge of current routine, to be able to cope with new conditions that may arise In both nations the really capable men will ultimately become masters of their subject, but the Frenchmen will tend to approach the particular through the general the concrete through the abstract, while the Englishmen tend to reverse the process

French mathematical books give a lucid account of general theories, but too often leave them in the air, without investigating their detailed application French mathematical students, if we may judge from their text books, work very few examples M le Chatelier has deplored the fact that too many students confine themselves to learning their lecture notes by heart He considers that they should work out examples for themselves, but regrets that this ideal seems impossible of attainment In England, on the other hand, the working of problems is firmly established as the essential feature of mathematical study Unfortunately, this feature, so good in moderation, is apt to be carried to extremes, as in the old Mathematical Tripos, which was considered to be largely responsible for the sterility of many who should have contributed to the advancement of their subject

In France there is no lack of research in pure mathematics, and here the instinct of generalisation finds a legitimate and fruitful opportunity Until the present century, British mathematicians have done best in applied mathematics, where the somewhat incoherent and not fully logical work of men like Maxwell has proved to be of more permanent value than the more closely knit and elaborate

efforts of French writers which have now fallen into the background However, in recent years a change has taken place At least two English pure mathematicians have a world wide reputation, while the new syllabus for French schools and colleges is much less abstract than the old Perhaps at last the two nations are learning from each other

We shall now deal briefly with the special features of the books under review

(1) Profs Painlevé and Platrier cover a much wider range than any English course of mechanics, for in addition to the usual rigid dynamics, hydrostatics, and hydrodynamics, there is a thorough treatment of elasticity, a little about steam engines, gas engines, and turbines, three short chapters on aviation, and finally both the special and general theory of relativity Until 1929 the course was lithographed, but the excess of material caused this arrangement to break down It is to be hoped that the effect upon the students will not be similar But if it is really necessary that they should have to be taught such an enormous range of subjects, they certainly have it presented to them in the best possible manner The section on gyroscopic motion is particularly notable

(2) and (3) The second and third books on the list are, like (1), part of the course at l'École Polytechnique, the students of which, it must be remembered, are selected by severe competitive examination (2) M d'Ocagne begins with homographic and other transformations, and then goes on to the differential geometry of plane and skew curves and of surfaces, and to line geometry The later parts of the book deal with applied geometry, including mechanism, graphical statics, graphical integration, and finally nomography (3) Prof Hadamard includes potential, calculus of variations, analytic functions, elliptic functions, differential equations (ordinary and partial), and probability The book differs from the well known courses of analysis by Goursat or Picard in that it contains many references to problems in mathematical physics, which add considerably to its interest It is pleasing to notice that the French, sometimes said to be the most insular of nations, have discovered the merits of the numerical method of solving differential equations given by the Englishman, John Couch Adams, the account given here is taken from a Russian contribution, written in French, to a French journal

(4) M Garnier has written out the elementary course in analysis and geometry, taken in the first six months at the University of Paris, by those who are preparing for a study of the physical sciences The first part deals with calculus, infinite series, and complex numbers, and authors of English elementary works could consult it with advantage for elegant methods of treating bookwork The second part has a very brief treatment (43 pages) of curves and surfaces of the second degree (quite inadequate from an English point of view), and then more than a hundred pages of differential geometry

(5) Prof Deltheil has prepared a part for the extensive treatise on probability edited by Borel It deals with the theory of errors and least squares on classical lines It is, from its own point of view, quite good, but we regret that the opening chapter is devoted to inverse probability without any mention of the condemnation of this theory by Dr R A Fisher, whose work on small samples, treated by the 'method of likelihood', seems of fundamental importance

(6) Prof Julia's book is an attempt to link up geometry and the theory of functions A study is made of certain transformations, in particular of a circle into itself These lead to some of the fundamental inequalities of analysis A sequel to this volume will deal with the researches of Lindelöf and Littlewood

(7) The last book on our list is by a Russian, but it owes a good deal to French influence, and the author's originality in arriving at mathematical results by way of philosophy is eulogised in a preface by Lebesgue It deals with the difficult questions of the theory of aggregates, which are on the border line between mathematics and philosophy In this subject it seems difficult to arrive at the truth, and the author considers that some work hitherto generally accepted is fallacious "Philosophers", said Einstein, "are children who play with words", and M Lusin concludes by warning us that philosophic considerations are always vague, and that we must rely on what may be called observed mathematical facts

The Great Zimbabwe Problem

The Zimbabwe Culture Ruins and Reactions By G Caton-Thompson Pp xxiv + 299 + 74 plates (Oxford Clarendon Press, London Oxford University Press, 1931) 25*s* net

IT is believed that Miss Caton-Thompson's admirable survey of this problem will finally lay to rest a controversy which has now continued for more than thirty years, in fact, it may be flippantly described as 'the great Zimbabwe myth', and few

in England will credit the heat which this discussion engendered An idea sprang up, soon after the discovery of the ruins by the Rhodesian pioneers, that they were of immense age, and the opinion grew that Rhodesia was the great source of the alleged wealth of the Sabæans, the ruins being the remains of a fortress designed to protect the gold trade, others, for some reason, claimed that they were built by Phœnician traders These theories were encouraged by Bent, who explored the ruins about 1891, and to some extent by Hall and Neal, who did further work there about 1901 The pronouncements of these investigators appealed to a public in South Africa who revelled in the romantic atmosphere, which was fully exploited by journalistic pens In fact, the fervour evoked was so great that anyone who was bold enough to express doubt was looked upon as a terrible iconoclast, if not worse

Randall MacIver in 1905 carried out some careful excavation work at Zimbabwe and other places, and he was the first person to place the solution of the problem on a scientific stratigraphical basis As is well known, he reported that nothing could be found which could be dated as being earlier than medieval times, and as regards the architecture, it exhibited no trace of Oriental or European origin

These conclusions produced an angry storm of criticism and did little to dissipate the cloud of misconception A local worker in Rhodesia, Mr J F Schofield, however, reopened the discussion in 1925 and produced some pertinent evidence Most professional archæologists were all along satisfied of the soundness of MacIver's conclusions, but the technique of archæological research has progressed in the last twenty five years and therefore the British Association decided that, as it was visiting South Africa in 1929, it would be a fitting occasion for an effort to settle a number of points which it was felt had been incompletely dealt with by the MacIver Expedition Miss Caton Thompson was entrusted with the mission and, accompanied by Miss Norie and Miss Kenyon, spent some five months on her task

The results are set forth in the volume now before us, and they provide an example of the best systematic archæological work of to day, and it is believed that the logic of the deductions cannot fail to disperse the misconceptions which have for so long persisted It is difficult to understand that any modification of current ideas regarding the origin of the ruins should be considered to damage their interest, a little reflection will show that this is not the case, and it is to be hoped that Miss Caton-Thompson's investigations will prove a basis for, and also a stimulus to, further archæological research in South Africa and Rhodesia, for they afford a pattern as regards method and the various unanswered questions are clearly specified

Miss Caton Thompson, upon arrival at the site, was faced with the problem which all archæologists have to decide, namely, "Where shall I, in the time at my disposal, with the means at my command, be likely to obtain definite results?" The main enclosure at Zimbabwe had been dug over in every direction for years past by prospectors and archæologists, thus being ruined by disturbance She therefore decided to explore fully, in the first place, the Maund ruins near by, for there is reason to believe that they are coeval with the main buildings, and, further, the cement floor which is such a persistent feature in these ruins was more or less intact This floor, of course, seals off everything prior to its formation and it therefore is of definite stratigraphic value, as constituting a datum level, and in a research, the particular object of which was to discover datable articles in undisturbed layers of deposits, it is thus of great importance providing the evidence is carefully interpreted

Two distinct periods of occupation were proved, one marked by the stone walls and the cement floors and a later one characterised by mud mounds, the degraded relics of buildings, the work of successors to these sites It is of great importance to note that practically everything found was, beyond doubt, of African origin As on previous occasions a few exotic sherds of pottery and some foreign beads were found In some cases the beads were in association with skeletal remains of Africans These objects were evidently traded from either Sofala or Tete, and the wonder is that there are not more

The next site to be examined was the elliptical structure containing the conical tower which is the best known feature of these ruins As the author states "Around the famous tower have rallied all the theories of the exotic origin of the Rhodesian ruins and it was fitting therefore that it should submit to a final test"

With the permission of the Rhodesian Government, a tunnel was driven under the tower and a small collection of objects was obtained therefrom, but nothing to which any great age can be attributed and nothing of foreign origin After this a considerable amount of work was done at the so-called "Acropolis", and to avoid confusion due to previous excavation and refilling on the top of the hill, attention was wisely confined to dissection of the old rubbish-heaps which here and there are to

be found on the flanks Here again practically every object was of African origin

Miss Caton Thompson cast her net widely, however, and ignored no site which might be productive of useful evidence She therefore explored a number of ruins to the north east of Zimbabwe—Chiwona, Matendere, Mshosho, and Hubvumi, also Dhlo-Dhlo, some fifty miles to the west In none of these did she discover anything to conflict with the sequence found at and near Zimbabwe

Now with regard to general conclusions, MacIver's dictum that the ruins were medieval and post-medieval appears to be generally correct But Miss Caton Thompson concedes that the commencement date of the buildings may go back as far as the ninth century A D, this conclusion being based on the age determination of imported beads found here and there, but the earliest date from other evidence seems to be not earlier than the thirteenth century, and, curiously enough, the soapstone objects, upon the exotic origin of which so much argument has been based, appear, so far as can be determined, to come rather late in the sequence

It is, however, impossible and even inadvisable in the limits of a review to attempt to give a complete résumé of the methodical steps by which all these conclusions have been reached One thing becomes clear that it is mainly by the aid of meticulous research of this character that concrete evidence will be obtained regarding the various waves of people which have swept into South Africa from the north during the last two thousand years, and which are loosely termed the Bantu invasions

The work is well produced and profusely illustrated C W H

Flora of Central Asia

(1) *The Plant Introductions of Reginald Farrer* Edited by E H M Cox Pp xi + 113 + 12 plates (London New Flora and Silva, Ltd, 1930) 50s

(2) *Plant Hunting on the Edge of the World* By F Kingdon Ward Pp 383 + 16 plates (London Victor Gollancz, Ltd, 1930) 21s net

(3) *Wild Flowers of Kashmir* (Series 3) By B O Coventry Pp xix + 100 + xxi-xxix + 51 plates (London and Leicester Raithby, Lawrence and Co, Ltd, 1930) 16s

(1) TO those who knew Farrer personally and to the many who have enjoyed his writings, this book will make instant appeal Farrer left his mark on English horticulture, and it is only fitting that there should be an account of his work and especially of his venturesome last years in western China and Burma The main part of the book is devoted to an annotated list of the plants secured in Farrer's journeys in Kansu in 1914–15 and to his explorations on the Burmese frontier in 1919–20 The introduction is adequate and eminently readable The writer of the book has had no light task, for the written records of these expeditions are imperfect, Farrer's plants and seeds from Kansu received but scant attention during the War, and his untimely death on the Burmese frontier left his last notes and collections in some confusion Fortunately, Mr E H M Cox had the opportunity of accompanying Farrer for part of his Burmese expedition and can therefore write with first-hand knowledge He has supplemented this by visits to most of the gardens where Farrer's plants are likely to be found His has been a careful analysis The results are satisfactory, and Farrer has been fortunate in his biographer

The book is well printed on excellent paper The illustrations are attractive, and among them are twelve coloured reproductions of paintings by Farrer in the field These illustrations, representing plants of the Burmese frontier, are of high merit and add much to the value of the book A few errors in the botanical names and terms have survived the proof-reading, but these are few

Apart from those who will read the book from interest in Farrer, the record of plants found by him in Kansu and Burma, with his annotations and descriptions, is such as must be recognised by botanical institutions and by those horticulturists (and they are many) who are keen on the floral treasures of these regions

(2) Those acquainted with Mr. Kingdon Ward's previous books of venturesome travel in central Asia, such as "The Land of the Blue Poppy", will welcome this noteworthy record of botanical exploration in one of the least-known corners of the world The first half gives an account of the author's journey in 1926 through that part of extreme north-west Burma bordering on Tibet and China, and the rest of the book is devoted to a subsequent journey in 1928 through the hinterland of the Assam Himalaya, again leading to Tibet and China It is an uninviting region to the traveller —with uncouth and unfriendly natives, dense jungles, and heavy rainfall To travellers of Mr Kingdon Ward's type it is redeemed by the interest of its flora, especially as regards its alpine plants

Little is known of the fauna and flora of this

region—a vast tangle of mountains between the Himalaya and the Chinese Alps The author has, in these and previous expeditions, made valuable contributions, both biological and geographical Many of the plants referred to in the text bear unfamiliar names, but that is simply because the plants were unknown previously and have but recently been described Even for the non-botanical reader the book well repays perusal It is written in an easy style and well illustrated

(3) Mr Coventry's book on the wild flowers of Kashmir is the third of the series, and is on the same lines as the previous two Fifty additional Kashmir plants are annotated and figured Every visitor to the delectable land of Kashmir who is interested in its flora, should take these three handy volumes as his companions The only alternatives are the bulky seven tomes of the "Flora of British India" and certain published lists of the plants of the north-west Himalaya These lack illustrations and otherwise do not appeal to the traveller who is not a professed botanist The figures in the series under review are coloured and are reproduced from the direct colour photographs of the author They are of very high merit, not only in the reproduction, but also in the choice of the material The botanist may miss the dissections which are the normal accompaniment of botanical illustrations, but the author has caught the *facies* of each plant so well that they need not be regretted With the adequate and clearly expressed text, the results are very satisfactory, and lovers of Kashmir will welcome additions to the series

Our Bookshelf.

The Animal Mind By C Lloyd Morgan Pp xii + 275 (London Edward Arnold and Co, 1930) 12*s* 6*d* net

IN the preface to "The Animal Mind", Prof Lloyd Morgan quotes the words of Don Quixote to the Duchess "God only knows whether there be any Dulcinea or not in the world " Let us be quixotic enough, adds the author, "and some behaviourists say that it is sheer quixotry—to believe that our Dulcinea does exist " This sentence sums up the difficulties of a biologist who is asked to review "The Animal Mind", if he does not agree with the *Weltanschauung* of the author Either you agree with Prof Lloyd Morgan's views about scientific method and regard the views he expresses about animals as a contribution to scientific knowledge, or you do not agree with Prof Lloyd Morgan's views about scientific method and are therefore compelled to say courteously but unequivocally that science is not advanced by speculations about what goes on in the mind as opposed to the central nervous system of an animal, and that the attempt to "put yourself in his place" is the very antithesis of the procedure which the scientific worker adopts in studying the characteristics of living matter

The method of extensive introspection or, as the author himself calls it, "putting yourself in its place", is set forth in the following passage, which refers to the author's observations on his dog Tony "Let me try to illustrate what I mean from what I may call the ball-situation and the stream situation, putting myself in Tony's place I, Tony, have learned to swim across a still pond and fetch things out of it Meanwhile I have been learning quite a lot in ball situations Among other things I have learned this that if I follow a swift running ball up to a wall, and from the wall as it rebounds at an angle " Those to whom this method of investigation appeals may refer to the text for the remainder of a soliloquy in which Prof Lloyd Morgan, alias Tony, tortures his motives like the heroine of a Russian novel

To those who place confidence in the method of Sherrington and Pavlov, the relevant issue is not whether Dulcinea exists, but whether Dulcinea belongs to fiction or to science They will not wish to rob Prof Lloyd Morgan of what comfort his Dulcinea can give him They will merely insist that her place is the library In the laboratory her charms will distract them from the serious business of the scientific worker

Untersuchungen an Luftwurzeln Von K Goebel und W Sandt (Botanische Abhandlungen, herausgegeben von Prof K Goebel, Heft 17) Pp 124 + 6 Tafeln (Jena Gustav Fischer, 1930) 12 gold marks

THE senior author of the monograph, Prof Karl von Goebel, during his journeys in the tropics made numerous observations upon the aerial roots of epiphytes, interesting and characteristic features of tropical vegetation, but he was not able to give them the systematic attention he desired Dr W Sandt has therefore continued to study them, under Prof von Goebel's direction, using the very fine collection of epiphytes growing in the glasshouses in the Munich Botanic Gardens, where anatomical and physiological studies were also possible The main point under examination was the growth habit of these roots before and after entering the soil Dr Sandt confirms the earlier observations of Sachs and others, that in these aerial roots the growing region may be extraordinarily long and that this adequately accounts for the remarkable daily increment of growth of some of these aerial roots

These roots, which grow obliquely, not vertically, downwards, are usually quite unbranched unless the apex is damaged Branch root primordia may be formed, but do not grow out so long as this vigorous growth of the main root continues When the root enters the soil, however, the zone of growth very rapidly becomes of the normal, comparatively narrow dimensions, and then the branch roots may

grow out, the main root apex also grows very slowly or not at all in water, whilst branch roots develop freely Numerous measurements on the growth of marked roots and some observations and experiments upon absorption by them are described, and the regions of the roots, growing in air and soil, are briefly compared in their anatomy

Experimental Mechanical Engineering for Engineers and for Students in Engineering Laboratories By Prof Herman Diederichs and Prof William C Andrae Vol 1 *Engineering Instruments* Pp viii + 1082 (New York John Wiley and Sons, Inc , London Chapman and Hall, Ltd , 1930) 40*s* net

THE precise methods of the physical laboratory have long since been applied in the realm of engineering practice In workshops, factories, engine rooms, and steel works, scientific apparatus is found in ever increasing quantity Specifications are drawn up with scientific accuracy and contracts have to be carried out within fine limits Not only during tests, but also as a matter of daily routine, records of pressure, temperatures, velocities, volumes, and analyses have to be taken at frequent intervals, and every engineer must be something of a physicist Of the scientific apparatus in use, there is an endless variety constantly being added to, and the need of an authoritative text book on the subject is apparent

To meet this need, the authors of "Experimental Mechanical Engineering" have compiled this work on engineering instruments, their construction, use, and calibration Chapters deal in turn with the measurement of length, area, time, speed, pressure, temperature, work and power, liquids, gas, vapours, and fuel analysis, exhaust and flue gas analysis, and lubrication They are well illustrated by diagrams, and references are given to the sources of information This is a book which should be in the library of every technical college, every drawing office, and of every engineer who is concerned with the testing and running of plant A second volume is to be published to cover the testing of power plant apparatus as laid down in the codes of the American Society of Mechanical Engineers

Plants of the Gold Coast By Dr F R Irvine Pp lxxix + 52 + 32 plates (London Oxford University Press, 1930) 5*s* net

THE author of this work, who is master of agriculture and biology at Achimota College, is anxious to commit to print the vernacular names of plants of the Gold Coast and their relevant proverbs, with interpretations, before they are forgotten in the changed conditions of modern life The work has been undertaken mainly to help African teachers and other Africans who are willing to take an interest in their flora

The introduction contains much of interest, amongst which the author summarises his investigations into plant lore, herbalism, and the economic uses of local plants A list of economic plants shows the species grouped according to their value for oils, fibres, timber, drugs, etc The lists of native names are a valuable record They are written in the new and unfamiliar script recommended by Dr Westermann and the International Institute of African Languages and Cultures The greater part of the book consists of an enumeration of the plants, with brief descriptions and notes on plant lore, in English The arrangement is alphabetical, under the botanical names The author welcomes suggestions for a future edition The experience he will gain in the meantime will undoubtedly lead him to reconsider the scope of the work

There are some good representative photographs of the vegetation and a few line drawings The low price of 5*s* is due to the financial assistance given by the Gold Coast Government to enable the author to achieve his object and place his book before the Gold Coast people

A New Algebra for Schools By Clement V Durell Parts 1 and 2 Pp ix + 328 + xxiv + xxiii + xv (London G Bell and Sons, Ltd , 1930) Without Appendix with Answers, 3*s* 6*d* , without Answers, 3*s* With Appendix with Answers, 4*s* 6*d* , without Answers, 4*s*

THIS book has been written for the ordinary pupil, and an excellent course has been devised whereby the initial difficulties in algebra, due largely to the symbolic notation, may be overcome In the early stages, the student is trained to think in numbers when using letters Simple practical formulæ are then developed in such a way as to exhibit the utility of the notation The volume, embracing parts 1 and 2, each corresponding to a normal year's work, carries the subject up to quadratic equations, and a characteristic feature lies in the numerous illustrations drawn from geometry, physics, and mechanics At the present time, when progressive teachers are strongly advocating a greater degree of unification in school mathematical subjects, such a book as this is very welcome There is an abundance of exercises to meet the needs of both ordinary pupils and those of special ability

An Index to the Chemical Action of Micro organisms on the Non-Nitrogenous Organic Compounds By Prof Ellis I Fulmer and Prof C H Werkman, assisted by Anella Wieben and Calvin R Breden Pp xiii + 198 (London Baillière, Tindall and Cox, 1930) 20*s* net

THIS book is a useful aid to biochemists wishing to know where to obtain information about the chemical action of micro-organisms The contents are tabulated to show the action of each organism on all the substrates which have been examined and in each case the products found, the authority, and the reference to the literature Each item is cross referenced under "Substrate" and again under "Products" So far as the writer has been able to test it, the information is fairly complete The present instalment deals only with organic, non-nitrogenous substances, and it is to be hoped that a further section dealing with other substrates will soon appear

Pliny's Water-Mill

A PHOTOGRAPH of a water mill which recently reached me from Kashgar in Turkestan is reproduced in Fig. 1. It has taken me two years to secure this photograph, and, so far as I can trace, no illustration of a mill of this peculiar type has hitherto appeared in any British or American publication, though references to such mills will be found in the works of a number of explorers in the Far East.

Copyright] [H. P. Vowles

FIG. 1

The interest of this particular mill lies in the fact that Pliny appears to have referred to water mills of a similar type in his "Natural History" (xviii. 23). It will be noted that the water wheel, which is undershot, does not drive mill stones through gearing, but operates pestles by a 'trip hammer' action. Pegs on the horizontal axle come in contact with the short ends of two pivoted levers as the axle rotates. The short ends are depressed alternately, the other ends of the levers—which carry pestles—then rising; further rotation of the axle releasing the levers so that the pestles fall by their own weight into mortars containing grain or rice.

After discussing hand operated pestles for crushing grain, Pliny remarks: "Maior pars Italiae ruido utitur pilo: rotis etiam quas aqua verset obiter, et molat." This has been variously translated, but I think the following gives the sense of the words correctly: "In the greater part of Italy is used a roughened pestle, with wheels which the water turns in passing, and so it grinds." The passage is admittedly obscure, but with the knowledge that the pestle and mortar water-mill actually exists, I think we may reasonably infer that Pliny refers to this type.

Further evidence, albeit indirect, is afforded by the fact that mechanism precisely similar in principle, though differing in application, is described and illustrated by Heron of Alexandria in his "Pneumatics". The difference lies in the fact that Heron substitutes a wind wheel for a water wheel, and a piston falling by its own weight in a cylinder for the pestle falling by its own weight into a mortar.

It is not improbable that this type of water mill was invented before the geared mill described by Vitruvius, and developed out of the (I think) still earlier water raising wheel used for irrigation purposes, a vague reference to which occurs so far back as Sumerian times ('Cambridge Ancient History", vol. 1, p. 461). There are two other types of water mill without gearing, but I have been unable to find any evidence for either in the literature of antiquity. Certainly no evidence is given by Bennett and Elton, in their "History of Cornmilling", in support of their view that the horizontal water wheel on a vertical spindle was known in Græco-Roman times, though one may reasonably suspect, from its primitive design and construction, that it was originally invented at an early stage of civilisation. I hope to give fuller details in a paper to be read before Section H of the British Association in September.

Classification for Bibliography of Science—A Problem

THE relations of bibliography to science with especial regard to classification, as brought forward in Dr. S. C. Bradford's recent articles in NATURE,[1] have for many years been my purposive study. I welcome the renewed and increasing interest in the problems involved. It is very regrettable, however, that these matters were not considered more wisely a quarter of a century ago. What can best be done now should indeed become a question of major importance to scientific workers, to bibliographers, and to librarians.

Classification, affirmed to be fundamental to scientific method, has not yet been applied to scientific literature methodically and in a scientifically organised system. This should now become a first concern of the national and international organisations. The reasons for this, so well stated by Dr. Bradford, have been urged by me elsewhere on broad grounds.

The International Catalogue of Scientific Literature rejected in 1896 the classifications then proposed, and the study of the question was remitted to the Committee on organisation.[2] In the face of this negation on the part of the scientific workers, the International Institute of Bibliography soon after adopted an arbitrary classification devised by an American undergraduate in 1875 for the college library he was then serving. This was the famous Decimal Classification of Melvil Dewey. Its undeniable disqualification is that it is illogical and unscientific.

This system separates Science in Class 5 from Philosophy in Class 1 and places it subsequent to Social Science in Class 3, which is remote from History in Class 9. Then Philology in Class 4 it dissevers from Literature in Class 8, so all the literatures are severed from their languages. Biology and psychology, so far from being treated as distinct, fundamental sciences, are misrelated and dispersed. Biochemistry is given place neither under biology nor under chemistry, nor even in the index. These few examples of the disorder and inadequacy that pervade

the system justify my criticism [3] that it is disqualified and inadaptable for scientific development.

The doctrine that such disorder matters little, that specific subjects however misrelated can be brought together by the index and by cross references, I have termed the subject index illusion. Without subordination of the specific to the generic, division produces dispersion of subjects that an alphabetic index does *not* countervail.

The International Institute, conceding to the proprietor's conservative regard for American public libraries, has engaged to maintain the basic order of the thousand subjects unchanged except for a few alterations in headings; but has been free to elaborate specific subdivision and to develop a complementary mnemonic notation. This however is too lengthy and complicated for bibliographic uses: for example, experimental psychology of children is marked 612.821.3-031, where three letters would suffice, *I* for psychology, *IB* for physiological and experimental, and *IBF* for that of children. The complexity is exemplified by such combinations as 9(44) "17" = 2 for history of France in the eighteenth century written in English, which an economical notation would mark simply with four letters, *MSLF* for the periods of the history of France, *MS* for the eighteenth century, *L*, and for English *E*.

Dr. Bradford has applied to the Decimal Classification the term 'Universal'. It may be regarded as international in some respects, but indeed not universal; it is not even internationally dominant. In America since 1900 it has been adopted by very few scientific and university libraries, the classification of the Library of Congress having been preferred. But there are strong objections to this system too, not only on scientific grounds but also because of its cumbersome complexity. Moreover, such a classification is not available for standardisation because it is not typical.

In systems of selection, of cataloguing, and of classification, co-operation and economy depend on standardisation; but we should consider how and in what measure. Would it pay to standardise an arbitrary classification for scientific bibliography? Does co-operation require that? I think not; and I proffer a constructive solution to the problem. The whole ground is treated comprehensively in my book on "The Organization of Knowledge and the System of the Sciences", reviewed in NATURE of Aug. 9, 1930, p. 199. That book is fundamental to a second volume offering a comprehensive study of the problem of bibliographic classification, which will probably be published this year by the American Library Association. It advocates co-operative development and standardisation of a basic classification and notation consistent with accepted principles and with the organisation of science, and adaptable to national, special and typical conditions and requirements. A definite plan for co-operation in selection, cataloguing, and classification was outlined by me at the Conference of the American Library Association at Toronto in 1927.

International co-operation is of so great importance to us now that we should avoid detraction save for social economy. But the problem of bibliographic classification is as yet unsolved. It is involved in library economies; it is immersed in a historical situation. We cannot avail ourselves of standardisation while bibliographers advocate one system and librarians adopt another, though scientific workers find both very unsatisfactory. It behoves scientific workers, therefore, to examine this matter for themselves and to undertake to solve it in an internationally organised system.

Isotope Effect and Hyperfine Structure of the Mercury Resonance Line

RECENTLY Schuler and Keyston [1] have made some interesting studies on the hyperfine structure of the spectral lines of thallium, from which they conclude that the hyperfine structure is due in part to a relative shift of the spectral terms due to two isotopes of thallium (203 and 205), *originating from differences in the structure of the electric field of the atomic nucleus*. The isotope splitting is greatest in the terms with relatively small nuclear moment splittings.

In connexion with the investigations on hyperfine structure of the mercury resonance line 2537 A., I have been able to confirm by experiments the existence of the above mentioned effect. I investigated the hyperfine structure of the mercury resonance radiation excited with different combinations of the 2537 A. line components, the isolation of the components being realised in the way described in a former paper.[2] These experiments showed that every component gives a pure resonance effect: this proves that the normal $1\,{}^1S_0$ level of the mercury atom is single.[3]

Further, my studies on the influence of admixture of non-extinguishing foreign gases to the resonating vapour proved that the components of the 2537 A. line can be divided into two groups: (1) components

FIG. 1.

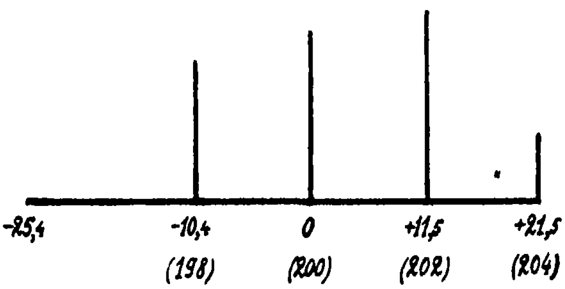

FIG. 2.

with an independent existence: even if considerable quantities of foreign gases are added (40 mm. nitrogen) they show the pure resonance effect—such are the components 0 and +11·5 mA.; (2) components which show a coupling such that they appear all together with the exciting line (−25·4 mA.) with greater additions of foreign gases—such are the lines −25·4, −10·4, and +21·5 mA. The lines of the first kind belong to different isotopes, those of the second to the same kind of atoms. The splitting of the latter is thus certainly due to the existence of the magnetic moment of the nucleus, which would in part confirm the hypothesis suggested by me elsewhere.[4]

The relations of intensities of the three lines of the second group in monochromatically excited resonance radiation with the −25·4 mA. component, in the presence of large quantities of foreign gas (represented qualitatively on Fig. 1), as well as my new investigations on the Zeeman effect in absorption in fields up to 15 kilogauss, show, however, that the structure of the 2537 A. line is certainly more complicated and arises from the incidental overlapping of the lines belonging to different isotopes. The relationships

to which the above mentioned investigations lead are represented on the Fig 2 (isotopes with zero nuclear moment) the lengths of the respective lines indicate their relative intensities These intensities, or the absorption coefficients, do not give us directly the proportion of the various kinds of isotopes, because the probability of the transitions may not be the same for different isotopes, which was demonstrated by me in the case of the 2537 A line [2] For this reason a correlation based on the intensities, as Schüler and Keyston have done (cadmium, thallium), cannot be considered as convincing

In the case of the line 2537 A, calculations can be made using the isotope concentrations given by Aston, which are not subject to the above mentioned objections, for the life period of different components is known [3] They show that if we attribute the lines 0 and + 11 5 mA to the isotopes 200 and 202 (in arbitrary succession), the three lines represented on Fig 1 must be attributed to two isotopes, 199 and 201 (overlapping of a doublet and a triplet ?), with nuclear moments equal to an odd multiple of 1/2 This last conclusion follows from the fact that in the parallel Zeeman effect the parallel zero components, which show a Paschen Back effect in higher magnetic fields, are not observed

It is curious that the direction of the isotope shift of the lines shown in Fig 2 is opposite to that observed with thallium and to that resulting from the motion of the nucleus around the centre of gravity of the atom This shift has at the same time a relatively high value of c 0 2 cm^{-1} for each addition of two protons, which is, however, nearly a half of the shift observed on the line 5351 A of thallium [1] It is produced probably by the modification of the electric field surrounding the nucleus, as resulting from the addition or subtraction of two protons

A full report of these investigations will be published shortly in the *Bull Acad Polonaise*

Electron Polarisation

IF the free electron has the spin theoretically assigned to it, the theory [1] of the double scattering of electrons by single stripped nuclei would lead one to expect that when an electron beam impinged successively on two metal targets, the intensity of the secondary scattering would be asymmetric about the direction of incidence of the secondary beam

The majority of the previous experiments to detect this effect have been carried out either with slow electrons (a few hundred volts energy), small scattering angles, or reflectors of low atomic number Under these conditions no observable asymmetry is predicted by theory, and this is in accord with the results of most investigators

Chase [2] has reported that with 90° scattering from 45° lead targets, and with primary electron velocities of from 0 7 to 0 95 the velocity of light, the effect does appear, together with more striking features not predicted by theory With these high velocities, however, the theory loses much of its meaning, since in its formulation the radiative forces on the electron were neglected It seemed desirable, therefore, to look for the effect with a primary electron velocity of such a value that the predicted asymmetry should be easily observable, and yet the radiative forces should be small

The tube was constructed so that the electron beam reflected at 90° from a 45° tungsten polarising target impinged at normal incidence on a tungsten analysing target The intensities of the secondary scattering at an angle of slightly more than 90° could be measured at 0° and 180° of the azimuth without altering any part of the apparatus Only the faster group of electrons in the scattered beams was allowed to reach the measuring instrument, all others being prevented by the use of suitable retarding fields (1700 volts for a primary voltage of 10 kv) Rotation of the polarising target through 180° about the direction of the secondary beam and the use of a second filament at 180° to the first, was intended to reverse the spin asymmetry and to provide a check against possible diffraction effects in the analyser

It was found that with 10 kv and 1 kv electrons the ratio of the intensities at 0° and 180° of the azimuth did not differ by more than the experimental error (1 per cent) For purely nuclear, ideal scattering (in the sense of the Mott theory) the difference should have been approximately 13 per cent This figure is based on the theoretical idea that the probability of an electron being scattered in a given direction depends on the orientation of its spin axis It would therefore attain this value only if all electrons scattered 'into' the polarising target were rediffused with appreciable energy loss, so that the faster group of electrons in the secondary beam would be polarised to the degree predicted by theory

It would appear to follow from this experiment that either the free electron has not the spin theoretically assigned to it, or that the present approximate theory with its neglect of orbital electron scattering and radiative forces predicts an effect which would not appear in a more complete formulation

I am indebted to Prof O W Richardson for the suggestion of the problem

Hyperfine Structure in the Spectrum of Copper

THE principal copper doublet at λλ3248 and 3275 has been studied with great care in the fourth and fifth orders of the large concave grating of the Physical Institute at Tubingen Each line consists of a very sharp, narrow doublet of separation, 0 043 ± 0 001 A or 0 41 ± 0 01 cm^{-1}, the long wave length component being about twice as strong as the short wave length component

Extreme care must be exercised in the photography of this pair of lines They are the 'raies ultimes' of copper, and even when the copper content of the electrodes is so low as 0 001 per cent, the fine structure of the lines indicates the beginning of self reversal A similar phenomenon was noticed by Royds [1] in the green line of thallium

So far as we are aware, the only previous work on the fine structure of these two lines was done by Back [2] with the same apparatus as that used by us On the basis of the present work, it seems that Back's results can be explained by self reversal of the fine structure components It was possible, with 0 001 per cent copper in the electrode and the use of high excitation, to reproduce the results of Back Only when the copper content of the electrode had been reduced, to

a negligible amount (as an electrolytic impurity) and the excitation kept at a minimum did the structure of each of the lines appear as reported in this letter

With a view toward interpreting this hyperfine structure on the basis of nuclear spin, the lines were studied in a magnetic field of 43,350 gausses The Zeeman patterns of these lines have always been reported as simple D types Using very fine grained plates and especial care in development, each of the Zeeman components appears to be doubled, even when using less than 1 per cent copper in the electrodes But this doubling is considerably wider than the field less separation, and we therefore reduced the copper in the alloy (<0 001 per cent) and the excitation to a minimum Under these conditions, the Zeeman patterns of the lines consisted of extremely sharp single lines, showing that the former patterns were probably due to self reversal

The separation 0 41 cm $^{-1}$ can be attributed to the hyperfine structure of the $^2S_{\frac{1}{2}}$ level of copper, since this level is common to both lines The hyperfine structure of the ^2P levels is apparently very much smaller and could not be determined in the present investigation

The Velocity of Light

IN NATURE of April 4, p 522, M E J Gheury de Bray pointed out that the decrease of the velocity of light, if it exists at all, could be caused by the change of the earth's magnetic field But such an explanation of a change in the velocity of light could not easily be accepted, because the immediate relation between the velocity of light and the intensity of magnetic field for Maxwell's theory is unknown

Let us suppose that Maxwell's relation for the index of refraction for an insulator $n=\sqrt{\epsilon\mu}$ is correct, μ signifying the permeability and depending in ferro magnetic substances upon the intensity of the magnetic field Then, because the discussion relates to measurements of the velocity of light carried out in air, the change of the velocity of light in the sense of Mr Gheury de Bray's explanation would mean that the permeability, and accordingly the index of refraction of air, had changed (on account of the change of the earth's magnetic field) The index of refraction of air is 1 00029, and a simple calculation shows that within the last fifty years the index should have increased by some $6\ 7 \times 10^{-4}$ in order to produce a decrease of 200 km /sec According to Landolt Börnstein ("Physikalisch chemische Tabellen", vol ii 1923, p 959, I Ergänzungsband, 1927, p 525) it can be seen that this index had not changed between 1865 and 1925, the difference between the various values being $\pm 3\ 6 \times 10^{-6}$, moreover, the values do not show any systematic variation during the time

V S VRKLJAN

Zerjavićeva ul 16, Zagreb,
May 2

DR VRKLJAN'S contribution to the subject is welcome as tending towards the elucidation of the causes, whatever they may be, which are operative in creating the curious, and possibly significant, refusal of the observational evidences to endorse the theoretical dogma of the constancy of the velocity of light

Dr Vrkljan, however, has misunderstood me I did not express the opinion that a decrease of this velocity could be caused by a variation of the earth's magnetic field I pointed out that the latter no doubt affects the velocity of light and yet that, to my knowledge, no attempt has been made to investigate the relationship and allow for its effect on the observations, although the possible error has been reduced to 1 in 100,000 nearly I further allude at the end of this note to the possible existence of other factors which may also affect the sought value The only correcting factors applied are those for the pressure and temperature of the atmospheric air

The velocity of light is undoubtedly the most important 'constant' in the realm of physical science Theories are currently discussed which admit an expansion of the universe soap bubble fashion, if the ether be material -and there are still physicists who hold this view—such an expansion implies a gradual decrease of density of the ether, and the decrease of velocity of light with time follows as a matter of course To any unprejudiced mind, the observations conclusively put this decrease in evidence If the ether is a mere abstraction, yet its virtual properties must be consistent with the theories which purport to describe the structure of the universe, and therefore there should be somewhere in the scaffolding with which de Sitter's theory has been erected some mathematical counterpart of this particular result of the expansion of the universe, which causes the light to take longer, as time goes on to travel between two points of space defined by their position with respect to the whole, since this whole is expanding, and therefore the distance between these two points increases

I believe that in any other field of inquiry such a discrepancy between observation and theory would be felt intolerable Why it is suffered in the present case is not apparent It is, however, certain that if a decrease of the velocity of light were accepted on theoretical grounds, and if some misguided physicist attempted to demonstrate that it is constant, the present observations would be called to witness to silence him conclusively! Such is the strength of the observational evidence on which this corner stone of physics is actually resting!

The Conditions on Schrödinger's ψ

THE energy levels of an atomic system are found in wave mechanics by selecting the 'characteristic' solutions of a Schrödinger differential equation, and the conditions defining these solutions are usually stated as an arbitrary mathematical postulate chosen so as to secure agreement with experiment [1] This additional postulate seems to be unnecessary, however, the conditions follow naturally as a consequence of the physical foundations of the theory

Wave mechanics rest upon the following two fundamental laws

(1) ψ has the usual significance of a probability amplitude,

(2) When completely expressed, ψ satisfies always Schrödinger's time equation (or its relativistic substitute)

Characteristic value problems arise as a special case in which the experimental conditions serve to select a system in a 'pure state' as regards some variable, such as energy or angular momentum, which can be 'measured' physically To follow such a measuring process theoretically, one expresses ψ as a series in terms of that complete set of orthogonal character-

istic functions which belongs to the Schrödinger equation for the variable in question, each function corresponding to a certain value of the variable, the measurement can then be regarded as consisting in a physical separation of the terms in this expansion, followed by a detection of the system as being in a place or state corresponding to one of them,[1] in other words, as a generalised Stern Gerlach experiment.

The basic requirement for a characteristic function is accordingly that it shall constitute one of such an orthogonal family in terms of which we can expand any ψ that can occur in Nature. Since it follows from (1) that $\psi\psi^*$ must always be integrable in order that the total probability may be unity, the characteristic functions themselves must be quadratically integrable (or, in the continuous spectrum case, Weyl normalisable). The customary requirements of continuity and single valuedness of ψ or its derivatives are unnecessary as an addition to the fundamental requirement that ψ shall satisfy a certain differential equation. The condition that ψ shall be finite everywhere, which serves so well in atomic theory, is in almost all cases equivalent to the requirement that $\psi\psi^*$ shall be integrable. The possibility remains open, however, that in exceptional cases infinities may occur without destroying the integrability, as in the Dirac relativistic hydrogen atom,[3] and on this view such an infinity does not necessarily constitute a 'blemish' on the theory.

The basic postulates of quantum mechanics are necessarily somewhat abstract but when we have a choice, I feel that the less abstract form has decided advantages from the physical point of view.

An Apparatus for Recording the Ultra-Violet Light of the Sky

OBSERVATIONS of ultra violet light are being made in many towns and seaside resorts by means of Sir Leonard Hill's method of recording the fading of a solution of methylene blue in acetone. For simplicity it would be difficult to improve upon this procedure, but in winter, when the days are short, there are many times when the fading is too small to be observable by this method.

Experiments have been carried on here during the last year or two on an alternative method in which photographic printing paper is used to register the ultra violet rays.

A strip, 3 in × 1 in, of 'Ultra violet Glass', which is opaque to visible light but allows a band of rays beyond the violet from about 3400 to 3700 angstrom units to pass, is fitted into a slot 3 in × 1 in, in the lid of a shallow metal box, so that the interior of the box is illuminated only with ultra violet rays when the lid is closed. To measure the intensity of these rays a stepped 'wedge' is constructed of layers of a fine quality of thin tissue paper which provide ten grades of thicknesses through which the light may pass. A strip of photographic paper receives the ultra violet rays. This paper is laid on the bottom of the box, the wedge is put over it, the lid of the box closed, and the whole exposed to the light of the sky. At the end of the day the photographic paper is examined, and the greatest number of layers of paper in the wedge which the light has penetrated is read off. According to theory, this number is the logarithm of the intensity of the light. The transmission factor of the paper being known, it is easy to construct an arbitrary scale of light values.

The method is sensitive enough to allow a daily reading to be obtained all through the short days of winter except at such times when fog obscures light of every kind.

As the year advances from winter to summer and the light becomes stronger the wedge scale may need extending, and in that case a further suitable number of layers of the tissue paper may be superimposed on the wedge without detriment to the accuracy of the readings.

If necessary this photographic method could easily be adapted to give a continuous record of ultra violet rays by wrapping the photographic paper on a rotating drum.

The record of average monthly readings with this apparatus compares very well with the monthly averages of the methylene blue apparatus.

Observations are being carried on in Manchester, Rochdale and Hale (Cheshire), and they show a regular diminution of ultra violet light as we pass from the open country, through the suburbs, to the centre of a manufacturing town, where the light is found to be about one half of what is received in the country.

This is no doubt, due to smoke in the atmosphere, for direct experiments in the laboratory demonstrate that smoke is effective in obscuring ultra violet rays.

The Change of Density of Nitrobenzene with Temperature

IN connexion with the study of the dielectric constant of nitrobenzene as a function of temperature,[1] I have measured the density of nitrobenzene in the temperature interval between 5.6° C and 30° C, using the method described by H Kamerlingh Onnes and J D A Boks.[2]

I have already used this method in measuring the dependence of the density of ethyl ether upon temperature,[3] there is therefore no need to dwell upon the details. I will mention only that temperatures were determined with an error not greater than 0.003° C, the changes in the fourth or even fifth decimal of the value of density were still discernible.

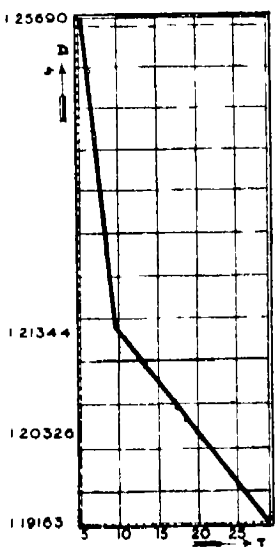

FIG 1

The density of chemically specially purified nitrobenzene increases from 1.1916 at 29° C up to 1.2134 at 9.8°. Beginning from 9.5°, there is a markedly more rapid increase of density with the lowering of temperature, at 5.5°, that is, in the neighbourhood of the freezing point, the value of the density is 1.2569. These changes of density appear distinctly on the accompanying graph (Fig 1).

In the neighbourhood of 9.5° there is a sharp change

of slope of the curve This temperature was incorrectly held by many authors to be the freezing point [4] In the present study I have definitely found that the freezing point is at 5 5°, at 5 7° nitrobenzene is distinctly liquid

It is to be noted that the slope in the density temperature graph is the more interesting because at the same temperature of 9 5° the dielectric constant of nitrobenzene, as was shown previously by me, shows a very sharp decrease Both this sharp change of the value of dielectric constant and the sharp change of slope in the density curve in the neighbourhood of 9 5° lead to the assumption that at this point nitrobenzene undergoes some, as yet not clearly understood, energy transformation

The Effect of X-Rays on Hair

IN NATURE of May 2, Messrs Asprey and Woods, writing on the subject of the molecular weights of proteins, mention that they have recently been doing some work on the effect of X rays on the elastic and other properties of animal hair They state that, after exposing unstretched wool for sixty hours to the full beam of a Shearer X ray tube, the fibres show many of the properties characteristic of wool which has been exposed in a stretched state to the action of steam They refer the effect to the disruptive action of high energy quanta on the length and adhesion of peptide chains, and mention that it must be closely related to the influence of various radiations on biological activity

The accompanying photograph (Fig 1) may be of

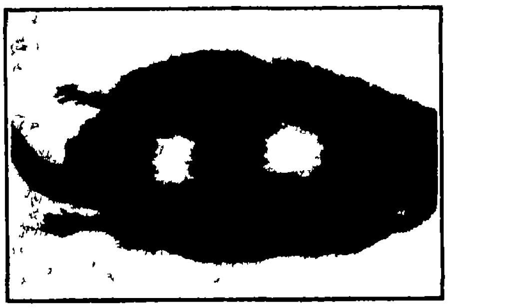

FIG 1

interest in this connexion, and is one which I showed a few years ago at a joint meeting of the Physical and Röntgen Societies The photograph is of a black rat which has been exposed over two small areas of the back to X rays generated in the region of about 150 kilovolts Some weeks after the dose had been given, the hair fell out and the new hair which grew was devoid of pigment and considerably altered in texture, the normal straight hair of the animal being changed to a rather thinner fibre which appeared slightly curly This result must, of course, be attributed to some action of the radiation upon the hair follicles, and the curliness of hair which regrows, once the surface has been epilated, is a not uncommon observation in children where epilation of all the hair of the head has been purposely brought about The doses in the cases mentioned are probably many times smaller than those mentioned by the authors

Stellar Structure

BY an unaccountable slip, a numerical error crept into our recent communication [1] concerning the nuclei of planetary nebulæ With the assumed data for a typical nucleus, it is the superficial area which is 1/43 of the sun's With mass equal to the sun, the mean density comes out 400 gm /cm [3], and with the probable mass 80 suns, as 32,000 gm /cm [3] This is still high enough to justify the classification of these stars with the white dwarfs, but degeneracy of the gas appears to be only beginning, rather than far advanced

The suggestion that the nuclei of planetary nebulæ are of high density and comparable in physical condition to the white dwarfs was made by Prof D H Menzel,[2] who gave convincing arguments in favour of his position We regret that we did not notice this in time to mention it in our letter

The subject has also now been dealt with by Gerasimovič [3] It seems possible that further additions to the list of 'white' dwarfs which we gave may be made from among the *O* and *B* stars, in accordance with the suggestion of K F Bottlinger [4]

University Representation

'UNFORTUNATELY, the case of the universities has been weakened by their own action in selecting members according to their political complexion rather than for their intellectual stature" (News and Views, NATURE, May 30)

The abolition of plural voting will inevitably result in a decrease (which may be considerable) in the number of votes cast in university constituencies The *Times* has represented the expected neglect of the university vote as virtual extinction Voting will tend to be left to those whose interest in the representation of 'stature' is strongest, and the ordinary politically minded voter with a degree may easily be in the minority

Is there no organisation adapted to turning this situation to advantage? The special opportunity seems to be this The assumed majority will be compact, relatively small, and accessible Its members, with special national needs in mind, should be prepared to excuse their representatives from attendance on those occasions when Parliament is pursuing what many of us regard as the merely political game The universities' representatives need not, therefore, find their work unduly heavy, although it might for some time be discouragingly light

The Nomenclature of Petrology and Mining

By SIR RICHARD REDMAYNE, K.C.B.

NOMENCLATURE in the scientific sense may best be described as a system of technical language by which the objects of any science are described, as, for example, the present language of chemical science, usually termed the modern chemical nomenclature, as distinct from the older and less perfect nomenclature. Consideration is here restricted to nomenclature in relation to petrology and mining, and to emphasising the desirability of working to secure a uniform and simple system in respect thereof, for the variety and complexity prevailing in petrological and mining nomenclature are very considerable and hampering.

A first step towards international universality of definition and name would be to secure unanimity of name, meaning, and notation nationally. Great diversity exists at present, especially in the domain of petrology—a state of disorder which is constantly increasing with the growth of terms and expressions. As demonstrating the doubtfulness or inconclusiveness which persists in petrological definition, one may take such well-known words as ‘freestone’, ‘coal’, ‘lignite’, and ‘ore’, all terms in very common use in petrological and mining literature. We find that such diversity of definition exists in regard to these as almost to amount to chaos. For example, in the county of Durham the term ‘freestone’ is applied to sandstone only, but in the West Riding of Yorkshire, to limestone. Albert H. Fay, of the Department of the Interior, United States of America, in his “Glossary of the Mining and Mineral Industry, 1920”, describes freestone as ‘any stone, especially a sandstone, that may be cut freely in any direction without a tendency to split”, which is perhaps as good and workable a definition as could be devised.

In considering the implication of the term ‘coal’ we are met with a great variety of meanings. Holmes defines coal deposits as a “general name applied to black carbonaceous deposits, derived from accumulations of vegetable debris which have been compacted by diagenesis into firm brittle rocks exhibiting a dull or shining lustre.” Fay's description is not in entire agreement with this—the reason perhaps being due to a difference of definition of ‘lignite’—for he defines coal as “a carbonaceous substance formed from the remains of vegetation by partial decomposition (U.S. Geol. Surv.). A solid and more or less distinctly stratified carbonaceous substance varying in colour from dark brown to black, brittle, combustible, and used as fuel, not fusible without decomposition, and very insoluble. In its formation the vegetable matter appears to have first taken the form of peat, then lignite, and finally bituminous coal. The latter by loss of bitumen has in some places been converted into anthracite or hard coal. Lignite gives a brown powder, coal a black; lignites contain a large percentage of water and ash.”

Here we have an example of the danger of tacking on a description to a definition. The description, as well as the definition, bristles with debatable matter. The stages of formation as set out are by no means agreed; the fact that there is loss of volatile hydrocarbons in coal on the application of heat does not prove that these hydrocarbons exist in the coal in the form of bitumen, bitumen being composed of solid or semi-solid hydrocarbons. Some true coals, again, contain a higher percentage of ash and of moisture than some lignites.

The term ‘lignite’ is used very loosely. Commonly, all immature coals are called lignite. It is used to embrace not only true lignites, but brown coals also. According to Holmes, lignite is distinguished from brown coal by containing more than 20 per cent of water, but this is not so. Brown coals are known which contain considerably more than 20 per cent of moisture and some lignites which contain less than that amount. As a matter of fact, lignite is immature coal formed from wood—it is found in brown coal deposits—whereas brown coal has earthy characteristics and probably owes its origin to peat, and lignite to the trees which grew where the peat was formed. The term best applied to those so-called black lignites which approximate to true coal—and there are many of them—is that adopted by the United States Geological Survey, ‘sub-bituminous’ coal.

The importance of a correct definition of ‘coal’ from a legal point of view alone is very great. The mineral mined at Torbane Hill, in Scotland, will be remembered in this connexion. It was this mineral which Mr. Young first used, in 1856, for the extraction of paraffin oil, which gave the start to mineral oil lamps in Great Britain and was extensively exported to the United States of America. The distillation of oil from this mineral led to much litigation. The great question was whether this mineral was or was not coal. The bulk of the evidence went to prove that it was not coal but a bituminous shale or clay. However, the use of the term ‘coal’ was retained. The litigation was in part between Mr. Young and the distillers of oil from cannel in England and the producers of petroleum in America, and in part with the owners of the ground from which the mineral was taken.

A commonly accepted definition of ‘ore’ is “a metalliferous mineral of economic value”, and of ‘ore deposit’ “a rock containing a metalliferous mineral of economic value in such amount that it can be profitably exploited.” But these definitions are inadequate and unsatisfactory, for there are ores and ore deposits which, by reason of poverty of metalliferous mineral contained in them, or for other obvious reasons such as difficulty of transport, cannot be profitably exploited at the present time, but may, on the exhaustion of richer deposits and on improvement in transport, be brought

within the category of profitability A better definition of ore would be "A metalliferous mineral of economic interest", or Crook's definition in his work on mineralogy, namely, "A metalliferous mineral which owes its economic value to the fact that it is smelted or otherwise treated to obtain a metal"

Various attempts have been made from time to time to standardise geological nomenclature, notably at the Congrès Géologique International in Paris in 1901, which, however, succeeded only in showing the wide divergence of opinion existing in that respect, and at which no final decisions were made Holmes, in his book, "The Nomenclature of Petrology", has taken stock of the situation and recorded the existing nomenclature in accordance with its current usage in so far as Britain is concerned The introduction to this work contains an excellent résumé of the question in relation to petrology With regard to his statement, "at the present time the field of petrology still contains many uncultivated corners, and, until the whole has become familiar ground, existing systems of classification and nomenclature must be regarded as on probation", there must be general agreement, but there will be considerable divergence of opinion concerning his belief that "stability will be approached not principally as a result of any Committee, international or sectional, but by the co ordinating work of a single petrological genius, whose authority, the outcome of his own success and influence, will be far superior to the merely temporary and democratic authority of a Committee" It seems to the present writer that a most useful end would be served by setting up, in the first instance, national committees with the object of securing, nationally, uniformity and simplification in naming and classification, and thereafter by an international committee, compounded of representation from the national committees, proceeding to deal with the subject internationally Perhaps the aid of the League of Nations might, with advantage, be invoked in this connexion

In regard to mining, except to the extent where the law has stepped in to regulate the industry and thereby brought about accuracy, clarity, and standardisation of definition, the terminology is varied, unsatisfactory, and often chaotic For example, the simple word 'pit' is applied indiscriminately to indicate a shaft, or a colliery with two or more shafts or pits and sometimes even to a mine worked by adits Then, again, the word 'colliery' is used to denote one unit or a collection of units of production under the same management In respect to these, the French nomenclature is better than ours Another example is the diversity which exists regarding the terminology applied to a bed of coal 'Seam' is the word used in the north of England, 'mine' in Staffordshire, and 'vein' in Wales Then the 'floor' of a seam is termed 'pavement' in Scotland and 'thill' in Durham and Northumberland These and many other examples show the advisability of agreeing among ourselves as to mining nomenclature before entering upon an international conclave, and that when we do discuss the subject internationally we do so in the first instance on broad and simple lines Agreement is far more likely to be reached if we do not strain at attaining too much in the first instance What is meant by this will be made clear by the following example

Hitherto it has been impossible to institute proper statistical comparisons between different countries, or make correct deductions in regard to output, consumption, and value of minerals, by reason of the absence of uniformity in statistical records It was in consequence of this that the Imperial Mineral Resources Bureau,* in the year 1924, drew up a statement of what it conceived to be the essential requirements regarding statistical returns from different parts of the British Empire Thereafter it engaged upon the work of drafting skeleton forms in which returns should be made in order to meet requirements in the light of the criticisms which the Bureau had received These forms were submitted to various government departments of Great Britain and the Dominions, India, and the Crown Colonies for criticism and comments, and the forms redrafted to meet the greatest common measure of agreement, being then passed to the economic statistical branch of the League of Nations

The ultimate end sought to be reached by the Bureau was an ambitious one, namely, to obtain, in respect of each country, statistical returns as to (*a*) production, (*b*) exports, (*c*) imports, (*d*) consumption, (*e*) value, (*f*) persons employed at mines and quarries, (*g*) accidents and health, and where possible (*h*) cost of production, (*i*) wages, (*j*) workmen's compensation It was realised, however, that it was not possible to obtain complete and uniform statistics under all these heads

It must be remembered that in connexion with returns of production and value, these are in many cases given voluntarily to government departments by the mine owners Thus, in Great Britain in the case of minerals, under the Metalliferous Mines Act the return of mineral sold is of a voluntary character, whereas in the case of coal the returns as to production and value are compulsory The variations in respect of weight are very great even with English speaking nations, the ton sometimes termed the long ton (2240 lb), the short ton (2000 lb), and the metric ton (2204 62 lb) being in use The Bureau suggested that within the Empire the long ton should be used, except in certain cases such as the precious metals, in which the usual practice should be followed of giving the weight in troy ounces

The views of the Imperial Mineral Resources Bureau have been very largely accepted by the International Convention on Economic Statistics held at Geneva in 1928, which in itself must be regarded as a notable achievement, but it now remains for the several countries to implement and bring into effective operation the decision of their representatives This has not yet been done, though more than two years have passed since the date of the Convention

* Now the Mineral Department of the Imperial Institute

Dietary Surveys

SOME account was recently given in these columns (NATURE, vol 126, p 963, 1930) of the results of studies of human dietaries in Scotland and the United States of America In both, it appeared that the caloric consumption was usually adequate, but that the intake of protein and minerals was frequently below the standard In all such studies, it is usual to take as standards figures which have been obtained in earlier investigations including experiments on metabolism, but it does not necessarily follow that these figures are applicable to people accustomed to a manner of living different from that under which they were originally obtained Careful studies, therefore, of the actual food consumption of families in different classes of society may not only point to dietary deficiencies but also to the necessity of revising our ideas of the adequacy of a diet This does not imply that previous investigations have given erroneous results, but merely that a different standard may be necessary when the food ordinarily preferred or available differs according to the customs of the people studied

To increase our knowledge of the actual food consumption of the inhabitants of Great Britain, Cathcart and Murray undertook an inquiry into the diet of a number of families in St Andrews[1] All classes, rich and poor, were included in the study, which comprised 745 persons, or one thirteenth of the total population The diet of each family was obtained for a period of one week by a skilled investigator and the energy value and distribution of the calories between protein, fat and carbohydrate, as well as the amount of money spent, determined No attempt was made to investigate the mineral or vitamin intake, the study being confined to the quantitative rather than the qualitative aspect of nutrition In all such work it is necessary to express the food requirements of women and children as a fraction of that of a man the total gives the 'man' value for the family The figures actually used were based on those given by Lusk and Atwater At the same time, it is also necessary in a week's study to make allowances for absences from meals or the presence of guests The 'man' value per family in this investigation was 3 37 and the 'diet man' value 3 51 The correctness or otherwise of the coefficients used for the 'man' value of women and children will be discussed later

The average of all the figures showed a caloric consumption of 3119 per man per diem, obtained from 89 gm protein, 119 gm fat, and 411 gm carbohydrate, the distribution of the calories between the proximate principles being 11 per cent from protein, 35 per cent from fat, and 54 per cent from carbohydrate These figures agree with those obtained previously in Great Britain and the United States, but differ from those of the standard diets of Voit and Rubner in the smaller consumption of protein and the much greater intake of fat This variation appears to be a national characteristic and has little relationship to income, occupation, social standing, or season

Thus, when the families were grouped according to total weekly income, it was found that the caloric intake per man was greater the higher the income, the increased calories were obtained chiefly from fat and to a lesser extent from protein The latter accounted for 11 per cent of the total in all groups, so that the low consumption of this dietary constituent appears to be due to choice and not necessity It was also clear that the number of calories obtained per penny spent increased as the income of the family fell

When the families were arranged according to their occupation, it was found that the sedentary worker consumed more food than the artisan As obesity is not common among the well to do, the excess calories must be metabolised, probably in part by the normal metabolism and nutrition being at a higher level than in the poorer sections of the population and in part by the habit of violent exercise Comparison of the diets of families of the same occupation showed that they varied considerably, apparently from variations in taste and appetite

The adequacy of a family diet is reflected in the state of nutrition of the children, which was found in this study to be usually satisfactory, in fact, in the better-class families the children were above standard and only in those of the unemployed were they below The variations from standard affected the height more than the weight, and the authors consider it probable that hereditary influences play a very considerable part in the subnormality of the children of the unemployed, as in the greater height of those of the better class families

One other point must be referred to the man value' coefficient implies that all members of the household vary their caloric intake in accordance with the value given to the man, this is probably not correct, and the point is of considerable importance when the diet is at the lower level of adequacy Examination of the actual food consumed by the different members of a few families showed that the man might consume 12 per cent more calories than was indicated by the 'man value' figure, made up from a 19 per cent increase in the protein and a 25 per cent increase in the fat intake, the mother, on the contrary, obtained the bulk of her calories from carbohydrate As a result of this work, a new set of family coefficients is tentatively proposed, somewhat lower in general than those actually used in this research

It may be of interest to refer briefly to another dietary study carried out under very different circumstances on another race[2] The natives of Nigeria studied have a high death rate and a low birth-rate with an almost stationary population they are undernourished, being below the white standard in both height and weight, they show a low resistance to disease, anæmia and intestinal toxæmia are common, and epidemics take a severe toll The staple diet consists of two cereals, guinea corn and pearl millet, with varying amounts of green leaves, fruit, partly cooked meat, sour milk,

and ground-nut oil The diet is deficient in protein, salts, especially calcium and iron[2] and vitamins Biochemical investigations showed that the blood sugar was above and the serum calcium below the generally accepted standards the urea and chloride output in the urine were low, indicating a subnormal consumption of protein and chlorine The protein intake was of the order of 85 gm per diem, whereas with such biologically poor proteins as those from guinea corn and millet, at least 110 120 gm should be considered the minimum necessary It may be pointed out that the total amount of protein consumed by the Hausa is about the same as that taken by the population of St Andrews, but the latter obtain their supply from both animal and vegetable sources, whereas the former utilise mainly cereal proteins of poor biological value McCulloch makes several recommendations for improving the diet of the Hausa more milk should be drunk and the breed of cattle improved by supplementing the deficiencies in their diet, the protein of the ground-nut should be eaten and not discarded as at present, 15-25 per cent ground nut flour, containing not more than 5 per cent oil, being added to the ordinary flours used, the salt consumed should contain small amounts of iodine, and the consumption of green leaves should be increased By these means, the protein, salt, and vitamin deficiencies could be overcome and the nutrition and resistance to disease of the population markedly improved, without any great interference with their present dietary habits

James Clerk Maxwell, 1831–1879

IN the history of science, names such as those of Galileo, Newton, Faraday, Darwin, Helmholtz, and Kelvin stand out like the peaks of a great range of mountains amid the surrounding lesser heights One such name is that of Maxwell, the centenary of whose birth falls on June 13, and to whose memory homage will be paid at Cambridge in October by Profs Einstein, Planck, Langevin, and others Maxwell's work belongs to the third quarter of the nineteenth century, and fifty eight years have now passed since the appearance of his "Treatise on Electricity and Magnetism", but the passing of time has shown much of his work to be of fundamental importance, and there is no investigator of physical subjects who does not owe something to him He died at the age of forty-eight, when in the prime of life, a man loved and honoured by all who knew him, for the kindliness of his disposition and the charm of his character Of his writings, it has been said that every one of them is stamped with the subtle and unmistakable impress of genius

Maxwell was born in Edinburgh and was an only son His mother died in 1839 and his father in 1856 The family name was originally Clerk, to which Maxwell had been added, thus becoming Clerk Maxwell, but while this is the correct form, it is by the second of the names that Maxwell is generally known Without the remarkable precocity of Young or Rowan Hamilton, Maxwell showed the possession of unusual powers at an early age, and as a schoolboy attending Edinburgh Academy he wrote a paper on oval curves At the age of sixteen he entered the University of Edinburgh, being taught mathematics by Kelland, physics by J D Forbes, and logic by Sir William Hamilton Three years later he left Edinburgh for Cambridge, where, after a term spent at Peterhouse, he entered Trinity College, having Hopkins as tutor In 1854 he graduated as second wrangler and Smith's prize-man, Routh being senior wrangler and tying with him for the Smith's Prize In October the following year, Maxwell was made a fellow of Trinity College, and in December published his first paper, on "Faraday's Lines of Force", a subject which was to engross much of his attention for the rest of his life

From Cambridge, Maxwell went first to Marischal College, Aberdeen, and then to King's College, London, holding in both institutions the chair of natural philosophy Four years were spent in Aberdeen and five in London, and to those years belong his memoirs on colours and colour-blindness, on the dynamical theory of gases, on the motion of Saturn's rings, and also his classic paper on a "Dynamical Theory of the Electro magnetic Field", read to the Royal Society on Dec 8, 1864 It was this paper to which the attention of Hertz was called by Helmholtz, just when Hertz was on the threshold of his fruitful investigations of electro-magnetic waves

From London, in 1865, Maxwell, who had suffered from serious illness, retired to his estate in Dumfriesshire—only, however, at the end of about five years to become the first professor of experimental physics at Cambridge His inaugural lecture was delivered on Oct 25, 1871, and on June 16, 1874, the now famous Cavendish Laboratory, erected by the seventh Duke of Devonshire, then Chancellor of the University, was opened Maxwell's great "Treatise on Electricity and Magnetism", "one of the most splendid monuments ever raised by the genius of a single individual", was published in 1873, in 1878 he delivered the Rede Lecture, and just before his death, which occurred at Cambridge on Nov 5, 1879, he had completed the editing of the electrical researches of his great forerunner, Henry Cavendish "The Life of Maxwell", by Campbell and Garnett, appeared in 1882, his "Scientific Papers", edited by Niven, in 1890, and in 1896, Sir Richard Glazebrook published his book "Clerk-Maxwell and Modern Physics" To Sir Richard Glazebrook we also owe the account of Maxwell in the "Dictionary of National Biography"

Obituary

PROF RAOUL GAUTIER

SCIENCE has lost a distinguished member, and English geodesists and astronomers a friend, in Raoul Gautier, who died on April 19, at Geneva

Raoul Gautier came of a family which has served Swiss and international science for many years We find Jean Gautier, for example, professor of philosophy and physics at the University of Geneva in the beginning of the eighteenth century An account of his observation of the eclipse of the sun in 1706 appears in *Philosophical Transactions* (vol 25, No 306, pp 2241-2246) In the early years of the nineteenth century another Gautier, Jean Alfred, was beginning to make his name as an astronomer To him is due the present Geneva Observatory built in 1830, although Arago seems to have shared to some extent the responsibility for it, in so far as his comments on the previous observatory did not lack candour In 1842, Émile Gautier was collaborating with Airy in the observation of another eclipse We hear of Émile in London, Oxford, and Cambridge He is not, perhaps, the only one who records a disinclination "pour parler d'affaires" after an excellent lunch in Trinity In 1883, after a truly international training, he took charge of the Observatory, and he is, perhaps, as well known as a meteorologist as an astronomer A point which impressed his countrymen, as well as his foreign colleagues, was that humanity and helpful understanding which stood both himself and his wife in such good stead during his term of office

Raoul, their son, was born in 1854 His education was singularly complete on the physical as well as on the mental side He travelled early, learnt English and German when young, and studied the classics, as well as mathematics, anatomy, and zoology He was a fencer, a mountaineer, and a horseman He became a man of the world with a singular charm of manner, at the same time as he laid the foundation of his scientific career When master of arts, he took up the family tradition of astronomy

Five years at Leipzig, education and friendship from Bruhns, Frederic Zoellner, Neumann, and other mathematicians, a visit to Uppsala, where Struve presided over a meeting of the Astronomische Gesellschaft, and where he met Gylden, Schönfeld, and Backlund, began to polish the expert Gautier's first essay in journalism was a report for the *Journal de Genève* on this Uppsala meeting His next undertaking was a study of planetary orbits (an inherited taste), and it was certainly a 'gros travail' to observe, to compute, and to analyse the facts that led to the publication of "La Comète périodique de Tempel 1867 II, étude consacrée spécialement aux apparitions de 1873 et de 1879"

This planet was not altogether a happy one for Gautier The strain of calculation brought him his doctor's degree, but cost him two years of enforced rest In 1885, we find him once more engaged in wrestling with the considerable influence of Jupiter's neighbourhood upon the same planet *Astronomische Nachrichten*, the *Comptes rendus*, and *Archives des Sciences physiques et naturelles* contain the results of his labours on the hoped for reappearances of 1892, 1898, and 1905 Unfortunately, the planet did not reappear

In the 'eighties, Gautier frequently visited the Neuchatel Observatory to work with its director, Hirsch In 1887, Gautier secured his doctor's degree in mathematical science At thirty three years of age, with three children, and three branches of mathematical science in which to qualify, Gautier confessed to a lack of that elasticity one expects of twenty, but he secured his degree, and in 1889 succeeded to the chair of astronomy and the directorship of the Geneva Observatory In 1885, he was given the chair of physical geography, re-established in that year after a period of eclipse We find him more interested perhaps in meteorology and oceanography than in morphology At this time, Gautier was professor at the University, secretary of the faculty of science, and secretary of the senate He was Vice Rector of the University from 1916 until 1918, and Rector from 1918 until 1920

An evidence of Gautier's activities in the 'nineties is contained in "Le Service chronométrique à l'Observatoire de Genève et les concours de Geneve avec une étude des épreuves instituées dans d'autres observatoires" This side of his work has found recent expression in the new Salle des Chronomètres (1924)

In 1900, Gautier observed the eclipse in Algeria, and in 1905 was with Sir Norman Lockyer in Majorca, where they had the mortification of finding bad weather whilst Algeria remained clear and fine In 1908, important spectroscopic observations on Morehouse's comet, and in 1909-10 Halley's comet, must have brought him back, with satisfaction, to his first love, whilst Nova Persei, Nova Aquilæ, and Nova Cygni he found "fort intéressantes"

As a meteorologist, Gautier began to install new apparatus in the Geneva Observatory in 1897 For many years he was engaged in the study and comparison of meteorological observations, prior to 1926, made in the vicinity of Geneva 1912 was almost wholly devoted to this end, and his results —not, unfortunately, final—are given in *Archives*, vols 31 and 32 His interest in meteorological observation at the Great St Bernard (where he installed a Fuess barometer in 1903) and his arrangements for pilot balloon observation will not be forgotten, nor will his services in the creation of the observatory at the Jungfraujoch In this latter enterprise he was able to count upon the generosity of fellow townsmen, who knew how to appreciate his services and contribute to his undertakings Gautier must have felt his retirement in 1928, but he was confident in his successor, and glad, in a measure, to relax the strain His public services had been great He was consecutively member, secretary, and head of the Swiss Geodetic Commission An active member of the old International Geodetic Association, he worked with Ferrero, Bakhuysen,

Arrillaga, and Helmert Copenhagen, Budapest, London, and Cambridge saw him at their meetings It was at the London Conference of 1909 that he first became well known to British geodesists Those of us who recall that Conference, at which Baron Eötvös also first made himself generally known, look back with regret on his manly figure and peculiar charm During the War, he acted as president of that geodetic association of neutral countries which helped to keep international enterprise alive In 1920, he was chosen to represent his country on the International Geodetic and Geophysical Union We met him at Rome, at Madrid, and at Prague, and the memory we shall retain of him is that of a courteous, statesman like gentleman whose ripe judgment and unfailing interest were of quite exceptional value to the Union

Gautier was elected vice president of the Geodetic Section of the Union in 1922 He was president of the Swiss National Committee for Geodesy and Geophysics, president of the federal meteorological committee, and a member of the international committee of weights and measures It does not surprise one that he was also the chief engineer of the 1st Corps of the Swiss Army We bid good bye, then, to as versatile a man as modern science can show, and to one whose peculiar social and administrative gifts were of the greatest help in any international gathering

DR FREDERICK MUIR

IN the death of Dr F Muir, which occurred on May 13, entomology loses one of its keenest and most experienced devotees Born in 1872, Frederick A G Muir served in his early life with the Eastern Telegraph Company and was stationed during different times at various localities on the eastern shores of Africa and also at Aden

Being an ardent entomologist from boyhood, Muir's tropical experience broadened and intensified his great natural ability as a student of insect life It was while he was still in the telegraph service that he first came into touch with the late Dr David Sharp In 1905 it was through Dr Sharp's influence that Muir adopted entomology as a profession and joined the scientific staff of the Hawaiian Sugar Planters' Association in Honolulu The worst troubles of the sugar cane growers in the Hawaiian Islands were imported insect pests, and it fell to Muir to explore many lands in order to discover the native countries of these pests, with the object of investigating their indigenous enemies In this work Muir made repeated and often extremely arduous journeys to such lands as Japan, China, the Philippines, Formosa, the East Indies, Queensland, and other parts

Few naturalists of recent years have had the same intimate knowledge of the Malay Archipelago as Muir His duties took him on more than one occasion to Java, New Guinea, Amboina, Ceram, and other of the islands, where he had to face hardship and sickness, and to work under improvised conditions of the most primitive kind Muir fortunately lived to see the results of his work on biological control bear abundant fruit The predaceous Capsid bug *Cyrtorhinus mundulus* discovered by him in Fiji and Australia in 1919 was the agent which finally achieved complete economic control over the sugar-cane leafhopper His work on the Tachinid fly, *Ceromasia sphenophori*, which after much journeying, he eventually obtained in New Guinea, has been the major factor in the subjugation of the cane borer weevil Perhaps his most striking success in the field of biological control was his introduction of the solitary wasp *Scolia manilæ* from the Philippines into the Hawaiian Islands, in 1916, where it achieved, in a remarkably short time, a high degree of control over the *Anomala* beetle

Muir's pioneer work in the field of biological control has had an enormous influence over the prosperity of the Hawaiian Islands, where his name is very widely known His interest in entomology, however, covered almost all fields of the subject On the taxonomic side he became the recognised authority on the difficult group of the Fulgoroidea His skill in minute dissection led him to explore various aspects of morphology, and his fundamental study, in conjunction with Dr David Sharp, on the genitalia of Coleoptera is a standard monograph In his travels Muir had little opportunity to publish, and his many papers were mostly written during periods at headquarters or while on leave In the few years of his retirement at Warnham, in Sussex, he took full advantage of the opportunity for unfettered research Severe illnesses, however, incapacitated him for much of the time but his optimism led him to plan work for the future Long subjection to tropical conditions unquestionably sowed the seed of illnesses that led to his premature death One of the last published contributions from his pen was in the form of a letter, dated May 11, entitled "Disease in Nature", which appeared in these columns so recently as May 23

At the time of his death, Muir was still a member of the scientific staff of the Hawaiian Sugar Planters' Association, his services being retained in a consultative capacity In 1918 he married Miss Margaret Anne Sharp, third daughter of Dr David Sharp, and leaves one son A few years ago he received the honorary degree of D Sc from the University of Hawaii, and in 1930–31 he was a member of the council of the Entomological Society of London, being a vice president for the year 1930

A D I

WE regret to announce the following deaths

Prof I P Church, emeritus professor of civil engineering at Cornell University, on May 7, aged eighty years

Prof Louis Dollo, professor of geography and animal palæontology in the University of Brussels and curator of the Royal Museum of Natural History, on April 19, aged seventy four years

Mr T T Gray, president of the Gray Laboratories of Newark, New Jersey, known for his work in petroleum technology, on April 27, aged forty nine years

Mr C T Heycock, F R S, Goldsmiths' reader in metallurgy in the University of Cambridge and Prime Warden of the Goldsmiths' Company in 1922, on June 3, aged seventy two years

News and Views

DR C DAVISON, author of "A History of British Earthquakes" and other important works on seismology, writes "With the reports of the first day only before us, it is difficult to give a satisfactory account of the greatest earthquake that is known to have disturbed Great Britain, on June 7 It is clear from them, however, that the earthquake was not of British origin, and it is fortunate indeed that the epicentre of so strong a shock lay far out in the North Sea For the exact position of the centre or of the region from which the first vibrations proceeded, we must rely almost entirely on seismographic evidence Some slight damage, such as the fracture or overthrow of a few chimney stacks, occurred at several places in the east of Yorkshire, such as Filey, Bridlington, Beverley, and Hull, at a few in the north of Norfolk, such as Wighton (near Wells), Cromer, and Sheringham With materials so scanty, it is impossible to fix the epicentre with precision, but it may lie about lat 54° N, long $2\frac{1}{2}$° E, or about 115 miles east of Hornsea in Lincolnshire"

"THE area over which the shock was felt includes quite half of Scotland from Elgin on the north, the Isle of Man, the whole of Wales with the exception perhaps of Pembrokeshire and Carmarthenshire, and all England but Cornwall, Devon, and part of Somerset In France it was observed at Cherbourg, near Lille, and at Calais and Dunkirk, in Belgium, at Brussels and Ostend, in Holland, at the Hague, Haarlem, and Amsterdam, and in the south of Norway Thus, the disturbed area can scarcely have been less than 760 miles long from north to south and 480 miles wide, or have contained less than 280,000 sq miles, that is, more than twice as much as that of any known British earthquake

IT was a happy thought that the rectorial address of Sir Arthur Keith to the students of Aberdeen, delivered on June 6, should have been associated with the celebrations connected with the 500th anniversary of the birth of Bishop Elphinstone, the founder of the University Sir Arthur took as the subject of his discourse "The Place of Prejudice in Modern Civilisation" He illustrated the significance of the opposing and yet overlapping mental characteristics generally spoken of as 'mind' and 'heart', the latter resident in the basal centres of the brain, the appetites and desires, the zest for life, unreasoned likes and dislikes—in a word, our prejudices These prejudices, local and national, are traceable to the prehistoric world, where the tribal sense was Nature's way of ensuring an isolation in which new traits could be developed They are an integral part of human nature the strength of nations which have not permitted the heart to overrule the head To ignore these prejudices is impossible, to root them out is to sacrifice a natural birthright So the universal brotherhood of man is seen to be as impossible of attainment, and even as undesirable, as the Determinism which, given a free hand, would make Europe again a vast conglomeration of warring tribal states Both reason and prejudice must be allowed a place in national policy, but the place of prejudice in modern civilisation should be that of servant, not of master

DR WHIPPLE of Kew Observatory, was among those Londoners who saw a great arc of light in the north eastern sky late on the evening of June 4, and he has kindly furnished some notes on the phenomenon as seen from Chiswick The curvature of the arc was very slight, but was unmistakable when it was viewed against a straight edge Its general appearance was like that of a rainbow, but without the colours of the ordinary rainbow Had the sun or moon been present in the sky the phenomenon would at first have been regarded as one of the many forms of solar or lunar halo, but its movement during the time that Dr Whipple observed it was sufficient to show that this was no halo At 10 30 P M (21 h 30 m G M T) it reached above the star Vega, but by 10 43 P M was 11° below that star at its highest point At 10 56 P M it passed through alpha Cygni at 11 4 P M just before low clouds hid it from view, 9° lower The breadth of the arc was about 2°, that is to say, about four times the diameter of the sun or moon

ACCORDING to information published in the *Daily Weather Report* of the Meteorological Office, Air Ministry, there was some cirrus cloud earlier in the evening moving from about south west Measurements of upper air temperature made at South Farnborough showed that conditions aloft were warmer than is normally the case even two months later, when the troposphere is generally at its warmest This warmth might have been expected, from the fact that a deep depression had been nearly stationary to the south west of Ireland for several days, causing northward movement of tropical air in front of it The progressive retreat of the arc towards the north-east horizon is consistent with the idea that the arc may have been some abnormal development of the cirrus clouds which were drifting in that direction Such a cloud might mark the boundary of air currents of different origin probably in the circumstances, both drawn from lower latitudes If anyone is able to furnish an account of observations similar to those made by Dr Whipple but at some distance from London, it might be possible to determine the height of the arc, which would probably be from four to six miles, if it was formed of cirrus cloud

PRESIDENT KARL T COMPTON of the Massachusetts Institute of Technology has been awarded the Rumford Medal of the American Academy of Arts and Sciences The award is made in recognition of Dr Compton's contributions in the field of thermionics, the study of electron emission from hot filaments and cathodes, and in spectroscopics, the study of matter by means of light waves Formal presentation of the medal will be made at the meeting of the Academy next autumn Dr Compton is the thirty sixth

recipient of the Rumford Medal, his brother, Dr Arthur H Compton, was awarded the medal in 1927 The Rumford Fund of the American Academy of Arts and Sciences was established in 1796 by Benjamin Thompson, the great physicist, who was a native of Massachusetts, and later became Count Rumford of Bavaria He was the founder of the Royal Institution The Rumford Medal is awarded to authors of the most important discoveries or useful improvements in light and heat, in any part of North America or in the American islands

IT is with pleasure that we offer our congratulations to Sir Oliver Lodge who attained his eightieth birth day on June 12 In doing so, we identify ourselves with the good wishes of the whole scientific world, since, during the last sixty years, Sir Oliver has not only built up for himself an international reputation for original conceptions and research in physical science but also as a brilliant expositor of scientific facts and principles His work has been recognised in a number of honours which have been conferred upon him by universities and other learned bodies In 1898, he was awarded the Rumford Medal of the Royal Society, in recognition of his researches on radiation and on the relations between matter and ether The discovery of electro magnetic radiation by Hertz was contemporaneous with the work carried out by Sir Oliver Lodge on the surging or oscillatory character of the transmission of electric discharges along wires He did much to make known in Great Britain the brilliant achievement of Hertz, and added much to our knowledge of the subject by his own investigations

FOLLOWING this epoch making work, Sir Oliver Lodge engaged himself with an investigation of the phenomena presented by Röntgen rays and the circumstances under which these rays are produced With these fundamental observations, he has carried on, for several decades, his contributions to our knowledge of radiations in ether, and also made suggestive speculations as to the properties of the ether itself The work of Sir Oliver on radiation, matter, and ether and its correlation with the works of such well known contemporary workers as Hertz, Michelson, and Morley is too familiar to call for any emphasis at present His researches into psychical phenomena began at a slightly more recent date The spiritual world which Sir Oliver considers to interact with the material, yet is not of it, has claimed his attention for a considerable time His stimulating address before the British Association in the Manchester College Chapel at Oxford in 1926 emphasised the necessity for a more scientific examination of these 'phantom walls' between the two worlds His exposition of his own views on efforts to find a place for life and mind beyond the world of physics, his fair discussions of the views of others, and his attractive methods for presenting his material, both in writing and in speech, have succeeded in giving him an exclusive place in the scientific world

THE Royal Research Ship *Discovery II* reached London on June 5, after a commission in the South Atlantic and Antarctic which lasted about eighteen months The scientific work accomplished includes extensive observations on the biological and hydrological conditions in the southern whaling areas and generally in the South Atlantic In each of the two seasons spent in the south, an intensive survey has been made of the South Georgia grounds, with other observations covering the whole of the Dependencies of the Falkland Islands, and the value of the results has been enhanced by the fact that these two seasons have differed very widely in respect of ice conditions Sectional lines providing very full data on both plankton and hydrology have been run between the Cape of Good Hope and the ice edge, and from the South Sandwich Islands to lat 15° N, while the ice-edge, a favourite resort of the whalers, has been examined almost continuously from Bouvet Island in the east to lat 101° W, a distance of about 2600 miles The *Discovery II* has also carried out coastal surveys of the South Sandwich Islands, Bouvet Islands, and parts of the South Shetland Islands and South Georgia Good results have been obtained with the Admiralty pattern of echo sounding apparatus, with which many thousands of deep water soundings have been taken The work is controlled by the *Discovery* Committee, appointed by the Secretary of State for the Colonies It has been carried out under the direction of Dr S Kemp, with Comm W M Carey R N (retd), in executive command

BY television is meant the transmission to a distant station by electrical means of moving scenes, which are viewed at the station practically simultaneously with their original occurrence Although it has been talked about for nearly fifty years, it is only six years ago since Mr J L Baird proved that it was practical Since then rapid progress has been made notwithstanding the great difficulties that had to be overcome Quite recently, screens have been shown in the theatre, and the audience has seen and heard people at a great distance away addressing them From the commercial point of view a great step will be made in advance if people can see sporting events – races, football, cricket and tennis matches, ceremonial processions, etc —on the apparatus in their own rooms and hear also an expert announcer describing them We learn from the *Times* of June 4 that the Baird Television Company, in co operation with the B B C, broadcast a television transmission of scenes from the Derby It included the parade of horses before the start and the scene at the winning post during the race This is the first attempt in Great Britain or any other country to secure a television transmission of a topical event held in the open air, where artificial lighting is impossible The engineers considered that the transmission was a success, and, more important still, they considered that it was quite possible that the outstanding interference difficulty with other transmissions could be overcome As the art of television has had to overcome many difficulties, including the apathy of electricians, we are glad that real progress is at last being made

JAMES CLERK MAXWELL was born on June 13, 1813. The celebrations of his centenary are to be held in

Cambridge on Oct 1 and 2 of this year, following the Faraday celebration and the centenary meeting of the British Association in London Delegates have now been nominated by the principal academies of the world and by the home universities, it is expected that about one hundred and fifty delegates will be present The celebrations will open with a ceremony in the Senate House, when the delegates will be welcomed and a memorial lecture delivered by the Master of Trinity Receptions will be given later at Peterhouse and St John's College On Oct 2 addresses will be given by Prof M Planck, Sir Joseph Larmor, and Prof P Langevin There will be a luncheon in Corpus Christi College, and, in the afternoon, addresses by Sir James Jeans and by contemporaries of Maxwell and a display of Maxwell apparatus and manuscripts in the Cavendish Laboratory The celebrations will conclude with a banquet in Trinity College Hospitality for delegates and guests of the University is being provided by the Colleges The University Press will publish a Maxwell Commemoration Volume, containing the addresses given at the celebration, with a contribution from Prof Einstein The Dean and Chapter of Westminster Abbey have given permission for a memorial tablet to Maxwell to be placed in the Abbey It is hoped that a tablet to Faraday will be placed at the same time, and that the two will lie together by Newton's tomb

THE issue by the British Association of a catalogue of the objects in the Memorial Rooms of Down House, Darwin's home at Farnborough, where he lived and worked for almost forty years, will be widely appreciated in view of the approaching centenary meeting of the Association in London Doubtless many of those who attend the meeting, especially from oversea, will be glad to avail themselves of the opportunity to visit this interesting and impressive memorial of "one of the greatest men of all time" Mr Buxton Browne, the curator and generous donor of Down House to the British Association, "to be held in custody for the nation", has restored the Memorial Rooms as nearly as possible to the state in which they were when Darwin lived there Much of the furniture is original, and, thanks to the generous assistance of members of the Darwin family and admirers of Darwin, the pictures and other objects and the articles which Darwin had in daily use are here in what was formerly their accustomed place Among the latest acquisitions are selections from the letters (in facsimile) from Darwin to Fritz Muller, the German naturalist, who was Darwin's correspondent in Brazil between 1865 and 1882 These letters were acquired in 1929 by Prof H Fairfield Osborn, of the American Museum of Natural History, New York. Prof A C Seward, professor of botany in the University of Cambridge, has recently expressed his intention of placing on loan at Down House the major part of the Darwin Library, which was bequeathed by Sir Francis Darwin to the professor of botany in the University for the time being The catalogue, which has been prepared by Mr Buxton Browne and the secretary of the British Association, gives brief historical and descriptive notes on the house and grounds, and is illustrated Its price is sixpence

THE subject for the Friday evening discourse at the Royal Institution on June 5, by Prof E W MacBride, was "Habit—the Driving Force in Evolution" Prof MacBride stated that evolution means the gradual growth of one species of animal into another All the available evidence shows that it has been an exceedingly slow process, and our knowledge of its actual course must be based on indirect evidence, for the amount of evolution observable during the span of a human life is infinitesimal There are only three reliable guides to evolution, namely (a) the relation to one another of local races within the species (b) so called lineage series of fossils where change in the same animal is observed as we ascend through a series of beds in the same locality, (c) the life histories of individuals All three classes of evidence when analysed yield the same result, that the individual steps in evolution are correlated with and caused by changes of habit the life history of the individual in its original form is seen to consist of superposed memories of a series of different habits That animals forced to live under different conditions and to accept different food from that to which they are accustomed acquire new habits and that these habits once formed are in some measure passed on to their descendants, has been proved by the experiments of Duckham on the white butterfly, by those of Heslop Harrison on the gall fly, and by those of Nuttall on the louse When by constant repetition a habit becomes deeply engrained in the hereditary constitution, the structure becomes permanently modified, because all structure is due to growth and habit affects growth It is suggested that as new habits imply the reaction not of a single organ but of the animal as a whole to a new situation, this reaction causes the deposit of some substance in all the nuclei of the body, including the nuclei of the germ cells When the germ cell nuclei become active from the new animal, this deposit is emitted at the proper period of development and affects growth and, through growth, structure

IN connexion with the International Colonial Exhibition which is being held this year in Paris and was recently opened by the President of the Republic, a Congrès International du Bois et de la Sylviculture is to be held on July 1–5 During this period there will be a day's excursion to Havre, and various receptions and so forth On July 6, a seven days' excursion will be begun, to visit some of the finest alpine forests in Savoie, Dauphiné, and Provence The work in Paris will be undertaken in morning and afternoon sessions of the several groups into which the Congress will be divided The aim of the Congress is to collect together all those who are in any way, either as owners, forest workers (State forest officers and others similarly employed), or commercial individuals, interested in the management of forests or in utilising forest produce, at one or other of the sections it will be possible to study economic, technical, industrial, and commercial questions which affect

forest management, as also international conventions which may assist in the better distribution of forest produce, in standardisation, and so forth The Congress will consist of French and foreign members and associate members Members may submit papers to be read and discussed at the Congress The French language will be the only one used at the sessions, and reports will be published in that language only The Congress is organised by the Touring Club de France, under the auspices of the Directors General of Forests and Technical Education, l'Institut des Recherches Agronomiques, le Comité national des Bois Coloniaux, and the Timber Group of la Confédération Générale de la Production Française All communications on the subject of the Congress should be addressed to Conservateur des Eaux et Forets, Secrétaire Général du Comité Exécutif, Touring Club de France, 65 Avenue de la Grande Armée, Paris (16e)

A COMMUNICATION from the U S Bureau of Standards, which appeared in the *Journal* of the Franklin Institute for May, on the liquefaction of helium, is of general interest On April 3 helium was liquefied in the Bureau's laboratory at a temperature of $-271\cdot2^{\circ}$ C, and this temperature was maintained for two hours It is only $1\cdot9^{\circ}$ C above the absolute zero It will be recalled that the late Prof H Kamerlingh after liquefying helium, reached a temperature of $0\cdot9^{\circ}$ A (NATURE, Mar 6, 1926, p 350) Helium has been liquefied previously in the Universities of Leyden, Toronto, and Berlin It has also been liquefied at the Reichsanstalt The temperature of liquid helium at atmospheric pressure is -269° C, but it was cooled further by reducing the pressure of the helium vapours over the boiling liquid by means of a vacuum pump The liquefier used is very similar to that designed by Dr M Ruhemann, of Berlin The helium is first purified and placed in a metal container and surrounded with liquid air at -190° C The helium, after being cooled by liquid hydrogen to -253° C, expands through a valve from a high pressure to a low pressure The amount of refrigeration is so small that the success of the apparatus depends on obtaining almost perfect thermal insulation The vapour pressure of the helium was determined, and hence its temperature was computed by a formula As further evidence, lead and tin electrical resistances were placed in the helium When the helium was liquid, both the metals lost their resistivity and became supra conducting It is interesting to remember that although tin, lead, mercury, and a number of other metallic elements and alloys become perfect conductors at these low temperatures, metals like gold, silver, and copper, which at ordinary temperatures are the best conductors, do not become supra conducting Many of the metals which at ordinary temperatures are poor conductors of electricity, at liquid helium temperatures become almost infinitely better conductors than gold, silver, and copper

THE liberation of eighty eight specimens of the Mandarin duck (*Aex galericulata*) on various London waters last year is worthy of note, as the bird is not only one of the most remarkable of wild fowl, but one of what may be called the world's most sensational birds, and the specimens in question were only wing-clipped, not pinioned, so that they have long ago, having moulted, regained the power of flight It is only in the case of wild fowl thus treated that the history of such birds can be really studied, for they are so much persecuted everywhere that on park waters alone can they be readily observed in most cases, while pinioned birds must always be inferior in some respect to intact specimens That they are often constitutionally impaired is shown by the fact that the Mandarin drake often fails to grow the characteristic and unique fan feather in the mutilated wing, while, as the species perches freely and nests in holes in trees, it cannot carry out its natural activities when deprived of flight Full winged birds have been living and breeding for years past on several private estates, and the species is probably now established as a British bird although seldom noticed, its semi nocturnal habits, and the fact that the showy male exhibits none of its decorations when in flight, would cause it readily to be overlooked—even pinioned birds in an enclosure cannot always be seen when looked for, if there be any cover available Up to Christmas of last year, a sufficient number had been seen to account for about half the total liberated, all had been ringed, and at least one has been reported this year as shot in Hungary, but most will no doubt settle down and breed in England somewhere or other

THE Zoological Gardens at Regent's Park are just now rich in ancestral and unique types of animal life Of particular interest is the exhibition of all the genera of dipnoan fishes, *Lepidosiren*, *Protopterus*, and *Neoceratodus*, and of the two aglossal anuran amphibians, *Dactylethra* and *Pipa* Among the mammals are to be noted especially the Anoa or pigmy antelope buffalo of Celebes, which looks much more like a large bush buck than an ox but, curiously enough, exhales in its breath the characteristic sweet odour of cattle This interesting species bred last year, and the calf is still to be seen, the pigmy hippopotamus has also bred recently The new bird house holds a particularly fine series of the family of barbets, little known birds which so perfectly connect woodpeckers and toucans that they are no doubt ancestral to both Of nearly a dozen species on view, the Asiatic *Megalæma virens* and its subspecies *marshallorum* strikingly recall in size of body and beak the smallest billed toucan, *Selenidera maculirostris*, *Chotorhea mystacophanes*, also Oriental, has a bill very like a woodpecker's, while the Abyssinian *Trachyphonus margaritatus* is so exceedingly unspecialised that it looks more like a small jay than anything else, and might well represent the ancestor of the triple woodpecker barbet toucan alliance Even more interesting is the Australian semipalmated goose *Anseranas*, which would have been better named *Anseribis*, for its feet, bare above the heel joint, scarcely half webbed, and provided with a long low placed hind toe, are those of an ibis, not of a goose, moreover, its plumage is not waterproof, it does not moult all its quills at once like other *Anatidæ*, and, as the specimens in the Waders Aviary in the Gardens show, is more ready to wade

than to swim It forms a most interesting contrast with the very specialised terrestrial goose *Cereopsis*, also Australian, and to be seen close by, along with our familiar grey lag

OUR notice regarding the law relating to treasure-trove (NATURE, April 25, p 647) has led a Scottish correspondent to point out that treasure found in Scotland must be offered, not to the British Museum, but through the agency of the King's and Lord Treasurer's Remembrancer to the National Museum of Antiquities in Edinburgh That is, indeed, so Our main object, however, in publishing the notice, was to keep the proper balance between finders, who are often scientific excavators, and the museums So far as we know, the law defining treasure trove is the same for Scotland as for England that is to say, treasure trove can consist only of objects of gold or silver, so that any attempt on the part of museum authorities to compel, by threat, the ceding of other sorts of objects, on the pretence that they are treasure-trove, would appear to be quite unjustifiable

ON more than one occasion we have commented upon the possibility of damage to agriculture which may be caused by the escape and spread of imported musk-rats in Great Britain We note with interest, therefore, that the Ministry of Agriculture and Fisheries has issued a notice requesting that any persons now keeping and breeding musk rats in England and Wales—whether for stock or pelts—would communicate at once with the Secretary, Ministry of Agriculture and Fisheries, 10 Whitehall Place, London, S W 1, stating the number of musk rats kept Since the chief interest of the Ministry must be the protection of the farmer, it may seem a little disingenuous to request from the musk rat breeders the evidence which may be used against them, under the plea that the Ministry is "anxious to obtain as full information as possible on the extent to which the musk rat (or musquash) farming industry is established in England and Wales"

THE Association of British Zoologists discussed at its general meeting the question of the payment of fees to zoologists for expert advice It is well known, as Prof E B Poulton says in a letter to us on behalf of the Council of the Association, that a somewhat unscrupulous public takes for granted the good nature [and affluence !] of zoologists in requesting their professional help without offering payment in return Whether it be a matter of the identification of a species or the delivering of a popular lecture, both demand the expenditure of time and energy, which the expert could have devoted profitably to his own purposes The Council's proposal is that, in the interests of their science, zoologists should demand fees for the work of identifying specimens and giving lectures They say that such a demand would enhance the respect felt for the science, just as medical advice tends to be valued according to the size of the fee We are not quite sure of this, there is a great difference between the urge of the man going to the best physician to have his own health established, and that of the man inquiring about an unknown insect Insistence upon fees, at least in trivial cases, such as the annually reiterated identification of *Sirex gigas*, would simply drive the sender to drop the subject, and a promising helper might thus be lost In the case of technical advice accompanied by identifications and in the case of lectures to outside bodies, fees might well be insisted upon Since the difficulty largely arises from the unwillingness of zoologists to be looked upon as mercenary, the Association would be making things easier for individuals if it were to print slips bearing a standard rate or rates of fees for advice and lectures, an impersonal hint which might be included with replies to importuners

SUGGESTIONS have recently been put forward that, so far as can be seen from photographs of the airship *R101* wreckage, certain of the lower members were crumpled as if by a compressive load, and that the cause of this was excessive bending due to the tail load arising from the maximum up position of the elevator From this it is inferred that elevators at the bows would be preferable This comment is unjustified, in that the findings of the Court were that the methods of stressing the structure were fundamentally correct, and that their application to this particular design had been amply confirmed by tests upon experimental sections, built especially for test purposes It is impossible to conceive that the possibility of having to use the maximum control moment had not been foreseen by the designers, and also the independent airworthiness panel Conditions producing compression in the lower members might easily have arisen at the instant of striking the ground at a shallow downward angle The forward movement of the nose would be arrested while the momentum would carry the tail end onwards The principal objection to placing the elevators in the bows is that the disturbance of the air flow along the body would increase the resistance and interfere with the stability The effects of either of these might easily be so great as to make the ship a practicable impossibility

REFERENCE was made in NATURE of May 9, p 717, to the issue of the *Power and Fuel Bulletin* by the British National Committee of the World Power Conference Further issues of the *Bulletin* have since been received, and the publication of these abstracts directs attention to an important question, namely, the rationalisation of abstracting Too many organisations are engaged in the abstracting of narrow fields of scientific and technical literature The constituent bodies responsible for this *Bulletin* in pooling resources have set an example which should receive consideration by others Whether the present production will satisfy everyone is, however, open to question The documentation by nations has certain advantages, but in this *Bulletin* it leads to the inclusion of material published in trade papers as scarcely veiled advertising matter This applies particularly to engineering plant, and the mere mention of such papers is doubtless sufficient The *Bulletin* is mainly concerned with engineering literature, and those responsible seem at times to deal with original research in the same manner Divergent views may be held as to what constitutes an abstract Should it be merely a table of contents, or should it be an attempt to give an idea

as to what the author claims to have done clearly and briefly, stripped of every superfluous word? In this *Bulletin* the first view seems to find favour, with results not always satisfactory

IT is announced in *Science* that Sir James Jeans has been given the honorary degree of doctor of laws by the Johns Hopkins University, Baltimore

THE Albert Medal of the Royal Society of Arts for 1931 has been awarded by the Council to H R H the Duke of Connaught, K G, "in grateful appreciation of his Presidency of the Society since 1911"

PROF H LEBESGUE, professor of mathematics at the Collège de France, and Prof A F Molengraaf, professor of geology at Delft, have been elected associates of the Académie Royale des Sciences, des Lettres et des Beaux Arts de Belgique

IN April last, Mr C W A Scott set up a new record for the journey by air from England to Australia It will be remembered that he took just over nine days for the flight (NATURE, April 18, p 604), thus beating Air Commodore Kingsford Smith's time by nearly a day He has now flown from Australia to England in eleven days, again beating a record set up by Air Commodore Kingsford Smith Mr Scott started from Wyndham, in the Northern Territories, early on May 26, and arrived at Lympne aerodrome on the evening of June 5, his time being given as ten days twenty three hours for the journey The last stage of the flight was from Brindisi to England, which he accomplished without a stop in very stormy conditions The machine he used was a small Gipsy Moth placed at his disposal by Lord Wakefield, it is an older pattern than the machine he used on his outward flight

TWO interesting and successful receptions were held at the National Institute of Industrial Psychology on June 1 and 2 Guests were received by the president, Lord D Abernon, Mr H J Welch, Lady Ruth Balfour, Dr Myers, and Dr Miles, and on each occasion about 350 guests witnessed a series of fourteen brief demonstrations, as well as films, illustrating the applications of psychology which have been made in different industries, and the methods by which psychologists are giving aid in the selection of workers The broad appeal which this very young applied science makes is evidenced by the distinction and variety of the guests Those responsible are to be congratulated, not only on drawing such large numbers, but also on the skill with which the guests were both instructed and interested for nearly two and a half hours The demonstrations included methods and results of industrial investigations, assembly operations, measurement of ventilation and lighting conditions, influence of rhythm on motor activity, a test for motor driving, selection tests, tests of perseveration, colour discrimination, movement study, vocational guidance, and psychogalvanic reflex These demonstrations well illustrated the very practical work which is being carried on by the Institute, both in industry and for private individuals, under the supervision of the director, Dr Miles, and the researches conducted under the direction of the principal, Dr Myers

A VOLUME of "Sydney University Reprints" (Medical Sciences, non-clinical) has recently been issued (series 9, vol 2, Nos 13 38, 1930) It includes two papers by W Bishop on the occurrence of lead in the egg of the domestic hen, papers on micro-methods of chemical analysis and estimation of chlorides in tissue by W R Mankin, and a titration method for the determination of potassium in urine by A Bolliger and E M Day, all of which should prove of service in the clinical pathological laboratory

APPLICATIONS are invited for the following appointments, on or before the dates mentioned —A research student at the Institute of Pathology and Research, St Mary's Hospital—The Secretary, Institute of Pathology and Research, St Mary's Hospital, Paddington, W 2 (June 16) A lecturer in agricultural botany at the Royal Agricultural College, Cirencester—The Principal, Royal Agricultural College, Cirencester (June 17) An assistant lecturer in geography at the University College of the South West of England—The Registrar, University College, Exeter (June 18) Three probationary forest officers under the Forestry Commission—The Secretary, Forestry Commission, 9 Savile Row, W 1 (June 18) A civil or mechanical engineer under the Safety in Mines Research Board, in connexion with the development of research into haulage problems in mines—The Under Secretary for Mines, Establishment Branch, Mines Department, Dean Stanley Street, S W 1 (June 20) An assistant pathologist at the South Devon and East Cornwall Hospital, Plymouth—The General Superintendent and Secretary, South Devon and East Cornwall Hospital, Plymouth (June 20) A full time graduate assistant in the Department of Engineering of the Leicester College of Technology—The Registrar, College of Technology, Leicester (June 23) An assistant lecturer in zoology and two research biologists, the latter with special experience with plankton work, at the University College of Hull—The Registrar, University College, Hull (June 23) A junior assistant at the Ditton Research Laboratory, East Malling, Kent, for work on the preservation of fruit—The Secretary, Department of Scientific and Industrial Research, 16 Old Queen Street, S W 1 (June 27) A registrar of Armstrong College—The Registrar, Armstrong College, Newcastle upon Tyne (June 30) Junior assistants in the Physics and Aeronautics departments of the National Physical Laboratory—The Director, National Physical Laboratory, Teddington (June 30) A professor of mathematics and an assistant lecturer in physics at University College, Southampton—The Registrar, University College, Southampton (July 6) A William Hudson professor of economics at Natal University College—Webster, Steel and Co, 9 St Helen's Place, Bishopsgate, E C 3 (July 15) A geography tutor at the Chester Diocesan Training College—Rev Canon Thomas, Diocesan Training College, Chester An assistant master to teach mechanics and metal work in the senior school of Sawston (Cambridgeshire) Village College—The Education Secretary, County Hall, Cambridge

Research Items

Nose-piercing as a Puberty Ceremony—Among the Kamia, an Indian tribe of Imperial Valley, south-eastern California, nose piercing is practised as the essential feature of the boys' puberty ceremony According to information obtained by Mr E W Gifford and recorded in *Bull 97* of the American Bureau of Ethnology, no youth can marry until he had undergone this operation The usual age for marriage was about fifteen years Not less than four boys can be operated on at one time, and if the number ready for the ceremony is insufficient it has to be postponed The chief takes the initiative, but the parents' consent has to be obtained Large quantities of food are necessary, of which the greater part is supplied by the chief and the rest by the parents The chief's 'policeman' removes the boys to the bush during the latter part of the night, and remains with them until they return to their homes The operation is performed by four operators, who use needles of screw bean wood Immediately after the operation the 'policemen' force the boys to run six or seven miles to a house and back They are then kept at the place of operation for four days, and are allowed to eat only watermelon and corn mush Each morning the 'policeman' washes their noses with hot water, and day and night men and women sing continuously near the place of confinement When on the morning after the fourth night they go home, they remain naked for a month and eat no fish, deer or jack rabbit The hole in the septum is kept open by a piece of arrow-weed stick Later, strings of white clamshell beads are worn hanging from the septum Sometimes these are long enough to hang in front of the lips and have to be lifted when the man wishes to eat

Food of the Sea Trout—Our knowledge of the food of the sea trout has been drawn only from isolated observations from widely scattered localities It is necessary therefore that a more intensive survey should be made of the food of these fish, both as regards the time of the year and its composition in different habitats A preliminary investigation with this end in view has been made by Dr C H O'Donoghue and Miss E M Boyd (*Fisheries, Scotland, Salmon Fish*, 1930, No 3) A start has been made by the examination of the stomachs of a number of sea trout from two localities, nineteen fish having been examined in May and June from Spey Bay, a purely marine habitat, and 144 at fortnightly intervals from the beginning of May to early September from the tidal limits of the River Forth near Stirling, typical of an estuarine habitat It was found that while all the fish from Spey Bay were feeding, the majority of those from Stirling had empty stomachs, those from the marine environment had been feeding chiefly on the sand eel (*Ammodytes lanceolatus*) or on the young metamorphosing stages of the herring The fish from Stirling, the stomachs of which contained food, had, however, been feeding more on crustaceans such as gammarids and mysids, and also on ephemerid nymphs, these estuarine fish also do not contain nearly so much food as do those from Spey Bay It is clear that continuous and intensive observations of this kind are needed to help to understand the large differences in rate of growth noticed in fish from different localities.

Anopheline Mosquitos in Southern Rhodesia—Southern Rhodesia, with an area of about 150,000 square miles, is a vast country for purposes of conducting an *Anopheles* survey. No 4 of the Memoir Series of the London School of Hygiene and Tropical Medicine (March 1931) is a report by Mr H S Leeson on observations carried out on these insects during the years 1926–1928 It deals first with the anopheline mosquitos of the country in a general way, and secondly, with those of a particular area where blackwater fever is endemic By diligently collecting mosquitos ever a wide area, it appeared likely that it may be possible to distinguish between those species prevalent in the zone of high blackwater fever incidence and those found elsewhere Special attention was paid to collecting in the neighbourhood of Shamva and Salisbury—the former being in a so called blackwater fever area, and Salisbury in a region now entirely free from that disease Five species of *Anopheles* made up 97 per cent of the total number of adults collected *A funestus* and *A gambiæ* occurred in largest numbers in the Shamva area, and when the incidence of malaria was at its highest When the number of malaria cases was lowest, *A funestus* was in hibernation and *A gambiæ* was entirely absent In the Salisbury area these two anophelines were extremely uncommon The freedom of Salisbury from blackwater fever is due largely to improved conditions of sanitation In order to reduce the number of anophelines in Shamva it is essential to create an environment unsuited to these insects The report concludes with a series of measures recommended to be carried out towards achieving this end

Crustacea of the Vanderbilt Museum—Miss Lee Boone describes a large number of Crustacea in the third volume of the "Scientific Results of the Cruises of the Yachts *Eagle* and *Ara*, 1921–1928, William K Vanderbilt, Commanding" (*Bulletin* of the Vanderbilt Museum Volume 3 Crustacea Anomura, Macrura, Schizopoda, Isopoda, Amphipoda, Mysidacea, Cirripedia and Copepoda, 1930) The previous volume (vol 2) dealt with the crabs This part is on the same plan and is a handsome book, well printed and with excellent illustrations, both photographic and in line The line drawings by Mrs Helen Ziska are to be commended specially The specimens consist chiefly of the Anomura and Macrura, although there are a few schizopods, isopods, and amphipods, usually represented by one or two species in each group, one cirripede, and three copepods, two of which are parasitic Notes made when the specimens were collected are, as before, a feature of the descriptions, and the information as to colour and habits, besides much that is new in the way of distribution, makes the work a valuable addition to our knowledge of the Crustacea Many of the species described are widely distributed, but some are very rare and so far only known from the type specimens Amongst the more interesting finds are a new species of *Porcellana*, *P rosamundæ*, from Simon Bay, Panama, two specimens of the interesting little abyssal hermit crab *Parapagurus pilosimanus abyssum* from 1100 fathoms, off Miami, Florida, and seven specimens of *Caligus aliuncus*, the male of which is recorded for the first time, from the skin of a dolphin

Drought Resistance in Plants—An important physico chemical study of the nature of drought resistance in Canadian crop plants is presented by R Newton and W M Martin in the *Canadian Journal of Research*, 3, 336-427, 1930 Ratio of water loss by evaporation under controlled humidity conditions, in the case of cactus segments and detached grass leaves, showed the remarkable ability of the cactus to retain moisture, but showed no relation to the relative

drought resistance of the grasses The osmotic pressures of the tissue fluids did not prove a reliable index to the capacity of the tissues to resist droughts, but bound water' content proved much more dependable This property was usually determined by the lowering of the freezing point resulting from the addition of known quantities of cane sugar to the expressed juice In proportion to the extent that water was bound by the plant colloids present the concentration of the cane sugar was greater than it should be as calculated from the total water content present, and the lowering of the freezing point accordingly increased In view of the considerable difficulty at present in the way of the interpretation of this concept of bound water the elucidation of these experimental results may have to wait but these physico chemical studies supply much necessary data for the further understanding of the complex factors involved in the plant s resistance to drought

Silver Leaf Disease of Plums —The sixth part of a very intensive study of silver leaf disease of plums by F T Brooks and his associates has just appeared (*Jour of Pomol and Hort Science* vol 9 No 1 Silver leaf Disease—VI by F T Brooks and G H Brenchley pp 1 29 March 1931) It is good to note that these workers have begun experiments on the incidence of disease on trees worked on different stocks though no definite results are as yet available The appearance of the so called gum barrier below wounds has been investigated and its role in impeding the spread of the fungus is discussed in the paper The protection of pruning wounds by soft grafting wax or home made white lead paint is again emphasised Manurial treatment of the host seems to have no direct effect on the incidence of the disease but vigorously growing plum trees are more likely to recover from the malady than those of weaker growth The danger of cutting back stock shoots in the process of propagation is shown and it is suggested that such wounds be protected by means of soft grafting wax The present paper raises many problems for future investigation especially those concerning the formation of the gum barrier of a tree which recovers from an attack of the fungus

Virus Diseases and Associated Protomyxean Organisms – Several workers on virus diseases of plants have reported that various primitive organisms are often found in the tissues of the hosts attacked Iwanowski so long ago as 1900 noted the association of bacteria with virus infected cells but could find no causal relation between the former and the disease A very detailed piece of work by Miss Ethel I McLennan has just been published in the *Australian Journal of Experimental Biology and Medical Science* vol 8 pt 1, March 1931, pp 9 44 and adds yet another such example to our knowledge A disease of hops which is very prevalent in Tasmania is described, and is adjudged to be in all probability a virus disease on account of the similarity of its symptoms to those described in England by Salmon and Ware, and sometimes called false nettle head The relation of the new disease to true nettle head is discussed, and the two are thought to be quite distinct from each other, since no eelworms are associated with the Tasmanian malady The protomyxean organism which has been isolated and cultured is *Leptomyxa reticulata* Goodey, var *humuli* nov var It is normally a soil organism and is associated with some of the virus infected plants The parasite has been found to enter the host through the cells of the epidermis or through root hairs, and it is thought that the virus disease lowers the resistance of the plant to such parasites No attempt to find a causal relation between the parasite and the virus disease has been made

New Guinea Tobacco – Dr A C Haddon s interest in the cultivation and introduction of economic crops and their bearing on the development of the people concerned is well known Anthropology Report No 11 published by the Government Printer Territory of Papua, entitled The Species of Tobacco grown in New Guinea is an example of this This investigation was initiated by Dr Haddon who in a preface states that he has long been interested in the decorated pipes of New Guinea and the distribution of the methods of smoking in the island A collection of the different kinds of tobacco found under cultivation in the island has been made and an examination of the material has been undertaken by Mr J S L Gilmour, of Clare College, Curator of the Herbarium, Botanical Museum Cambridge, who is the author of this report This examination involved the raising of many samples from seed So far as the material examined represents the types under cultivation it is shown that all of them are varieties of *Nicotiana tabacum* Linn and types of China Manila and Java tobacco are represented This confirms the opinion of Dr O Finsch (Samoafahrten , Leipzig, 1888 p 58) that this tobacco is *N tabacum*, but is contrary to the view expressed by J H Maiden in a paper contributed by him to the *Proc Linn Soc N S W*, 1888 on New Guinea tobacco which stated that East Indian Manila and Turkish tobaccos are the produce of *N rustica* Linn This statement of Maiden s was made although Mr Hugh Dixson a high authority on tobacco in New South Wales pronounced that the samples which were submitted to him by Maiden were the same species as the tobacco of commerce

Tidal Frequency of Earthquakes —The relation between tidal phases and the frequency of earthquakes is discussed in a recent paper by S Yamaguti (*Bull Earthq Res Inst* vol 8 pp 393 408, 1930) In earlier investigations on the subject the origins of the earthquakes considered were unknown Mr Yamaguti confines his study to the after shocks of the Kwanto earthquake of 1923 the Tango earthquake of 1927 etc in which the epicentres were distributed within well defined areas In all of these he finds that the frequency is greatest at or a little before, the time of low water at a neighbouring station while a secondary maximum appears before high water on the Kwanto curve and a little after high water on the other curves There is, however an interesting difference between the Tango after shocks that originated beneath the sea bed and on land on the northern side of the Yamada fault The former have two maxima $1\frac{1}{2}$ hours before and after high water the latter a principal maximum about low water and a secondary maximum about high water

Oceanographical Research North of Siberia —In the Norwegian magazine *Naturen* for January 1931 (vol 55) Dr H U Sverdrup, in his paper Resultater av Maudferdens Oceanografiske undersøkelser , describes the results of his oceanographical research in the seas north of Siberia the hydrographical stations being mainly in the region of the New Siberian Islands the East Siberian Sea, and, eastward, in the water between this and Alaska called the Chakotsk Sea The bulk of the work was done in the East Siberian Sea depth, currents and winds, salinity, oxygen content, and hydrogen ion concentration all being investigated There is much ice in these parts and samples were taken even when the vessel was ice bound Plankton samples were

taken to a small extent, the Chakotsk Sea having a good deal of phytoplankton in its surface waters. It is noted, however, that the phytoplankton, although it can live where the ice is, does not develop freely under ice bound conditions. The bulk of the work is on oceanographical hydrography, and there are clear maps showing the main regions with the stations and diagrams illustrating the various aspects of the researches which are interesting and valuable.

Diffraction of Very Fast Electrons.—An experiment is described by E. Rupp in the *Annalen der Physik* (vol. 9, No. 4) which verifies the de Broglie formula for the wave length of an electron—Planck's constant divided by the momentum—under conditions when the relativity correction to the mass is large. Using an interference apparatus similar to that of Prof. G. P. Thomson, with a gold scattering foil, the interference rings produced by electrons which had fallen through a potential difference of a little more than 200 kilovolts were obtained and measured. From the ring pattern the electron wave length was calculated to be $2.162 \pm 0.013 \times 10^{-10}$ cm., the lattice constants for gold crystals being taken from X-ray data; the corresponding quantity calculated from the de Broglie relation and the accelerating potential acting on the electrons was $2.183 \pm 0.035 \times 10^{-10}$ cm., showing that the relativistic formula for the change of mass with velocity is accurate in this region to at least one per cent.

Colours of Metallic Films.—Films of gold and silver have attracted a great deal of attention at various times on account of the colours which they impart to transmitted light, and have been studied by Faraday, Beilby, R. W. Wood, and others. An investigation of the effect of temperature on their optical properties is described by S. R. Swamy in the May number of the *Proceedings* of the Royal Society, and it has been shown that the electromagnetic theory of the phenomenon due to Garnett can be made to account for a great part of what is observed. Dr. Swamy makes the fundamental assumption that the effect of warming is to disintegrate a film, some parts turning dense at the expense of other parts which become thinner or vanish completely; the latter places act as effectively transparent windows, which transmit unchanged part of the incident light and so dilute the true absorption colour. This idea certainly receives support from the mottled appearance presented by the microphotograph of a heated gold film, but is perhaps inadequate to account for all of Prof. Wood's results.

Propagation of Magnetisation.—When the magnetisation of a ferromagnetic body alters with the specimen under the influence of a mechanical stress, the hysteresis loops contain abnormally large discontinuities. An investigation of this phenomenon, which is allied to the well established Barkhausen effect, is described by L. Tonks and K. J. Sixtus in the second April number of the *Physical Review*. It appears that the change in magnetisation starts at a nucleus. From this a magnetic wave travels away with a speed which is related in a simple manner to the field in which propagation occurs and varied from 500 to 40,000 cm. per sec. under the conditions studied. As the wave progresses, eddy currents are set up in the metal, and, by dissipating the energy available from the magnetic change, limit the velocity with which the change penetrates the specimen; the effect of changing the lateral dimensions of the piece of material indicates that the velocity depends primarily upon surface phenomena. A reasonable picture offered for what occurs is that the magnetic reversal takes place within a very small distance of an approximately conical surface—in a wire—the edge of the base of the cone being the front of the wave. In addition to depending upon the magnitude and nature of the stress, the effect changes with the composition of the material, but so far no new relation to other properties has been ascertained.

Electrical Discharges in Gases.—The April number of *Reviews of Modern Physics* contains a second article on electrical discharges in gases by I. Langmuir and K. T. Compton. The first article, which appeared earlier in the same journal, gave a summary of those properties of atoms and electrons, considered as individuals, which are important in conduction. The present paper deals with the collective behaviour of the particles under relatively simple conditions, and is largely an account of the electrostatics of charges which are distributed throughout spaces of definite shape. It thus differs from classical treatments of the subject in being not mainly concerned with charged surfaces only, but also to a large extent with rather general solutions of the Poisson equation. Practical knowledge of this nature is naturally of much value in the design of thermionic apparatus for the utilisation of high vacuum discharges, but is far from being confined to this, being fundamental both in the theory of the use of exploring electrodes for the analysis of various forms of gas discharge, and in the theory of the mechanism of the grid controlled arcs, or thyratrons, which are now finding many experimental and technical applications. The theory also differs considerably from classical electrostatics in its continual use of numerical data both with the view of practical applications and in consideration of the validity of approximations which are frequently useful or necessary; and, for similar reasons, it is usually desirable to express complicated results ultimately in series, rather than by the use of special functions. It is no exaggeration to say that these ideas which, although they are in a sense the logical outcome of the earlier work of Sir J. J. Thomson and of Prof. Townsend, have been carried to their present stage almost entirely by Dr. Langmuir and his collaborators at Schenectady, have revolutionised the outlook on the nature of electric discharges through gases, and seem likely to make it possible to analyse fairly completely the processes operative in any particular type.

Pipe Line Corrosion.—The extensive corrosion which has occurred on some sections of the pipe lines used by the oil companies of the United States has led to the co-operation of the companies and the Bureau of Standards in an investigation of its causes, and the results are given in the April issue of the *Journal of Research*. Nine pipe lines between the Gulf of Mexico and Kansas have been examined, and it has been found that every line has electric currents flowing along it, generated by differences in the states of the metal and of the soil where they come into contact. These currents are found to flow into the pipe from the soil where the soil has a high electrical resistivity, and out of the pipe into the soil where the soil has a low resistivity. The corrosion occurs where the electric current flows out of the pipe into the soil, that is at points where the resistivity of the soil is low, and at such places the pipes should be suitably coated. The Bureau has produced a simple apparatus for measuring soil resistivity, which consists of two sticks shod with iron cones connected by wires in the axes of the sticks through a milliammeter to two dry cells. The sticks, which are about the size of walking-sticks, are thrust into the ground about 20 centimetres apart, and the current read. From the current and the constant of the apparatus the resistivity of the soil is calculated.

The Royal Observatory, Greenwich

ANNUAL VISITATION

THE visitation of the Royal Observatory was held on Saturday afternoon, June 6 A large number of guests were present, and took part in the inspection of the instruments and other exhibits

The report of the Astronomer Royal to the Board of Visitors begins with the very welcome announcement that Mr William Johnston Yapp has made the generous donation of £15,000 for the purpose of providing a 36 inch reflector, with a spectroscope and a 34 foot dome This magnificent gift has been gratefully accepted by the Lords Commissioners of the Admiralty, and the order for the erection of the instrument will be placed with Messrs Sir Howard Grubb, Parsons and Co

Another satisfactory announcement is that the Lords Commissioners have sanctioned the purchase of a new transit circle the present one has been in use for eighty years the object glass has become so thin that it will not bear further repolishing, and many of the divisions on the circle are almost obliterated, attempts at recutting these have not proved permanent A model of the proposed new instrument was on view It will be, in general, similar to the reversible transit circle at the Cape and will be entrusted to Messrs Cooke Troughton and Simms, who made that instrument it will be somewhat smaller than the present instrument, an aperture of seven inches and a focal length of eight feet are proposed, also a motor driven micrometer for recording transits The roof will be in the form of two semi cylinders with axes running east and west, and sliding apart so as to give a wide central aperture The design is to give free circulation of air, and avoid abnormal refraction, with this aim the transit room will be put at some distance from other buildings It is recognised that the opening in the roof of the present instrument is too narrow and that the shutters, when open, impede the free circulation of air The collimators of the new instrument will be outside the main building

More than eleven thousand transits and circle readings were obtained with the transit circle during the year, the sun being observed on 131 days and the moon on 79 The report gives the errors of the sun in longitude since 1901, when Newcomb s tables were introduced, the error gradually rose from zero to 1 65″ in 1922 (observed greater than tabular), since then it has remained nearly stationary The errors of Brown's tables of the moon have steadily diminished from 7 1″ in 1922 (observed greater than tabular) to 5 2″ in 1930

The observations for the catalogue of 10,800 stars between N Decl 32° and 64° were completed last December The new catalogue will cover the regions 0° to 24°, and 64° to the pole The Astronomer Royal notes that this will probably be the last considerable undertaking with the present transit circle It is now considered unnecessary to observe stars fainter than magnitude 7 5 or 8 on the meridian, fainter stars are observed photographically on plates of large area, on the plan initiated by Prof Schlesinger

The 28 inch equatorial was used for observing 258 double stars, 52 of which were less than ½″ apart An electric motor has been installed for rotating the dome, this enables one observer to work the instrument without assistance The determination of stellar parallaxes with the 26 inch refractor has been continued, 1140 good plates were secured during the year, and 950 plates were measured, leading to the determination of 34 new parallaxes During November, December, and January 110 plates of Eros were obtained on 19 nights

With the 30 inch reflector the determination of the colour temperature of stars has been continued A Kodak standard acetylene burner (colour temperature 2360° K) is now used as standard instead of a carbon arc, a colour filter is inserted in the beam from the burner Each plate contains images of a high star, of two low stars for determination of atmospheric absorption, and of the burner The results indicate 13 000° to 14 000° for the temperature of a star of type Ao When the new 36 inch reflector is ready it will be used for this work As the 30 inch is on the same mounting as the 26 inch, observations of parallax and colour temperature cannot at present be made simultaneously

Photographs of the sun were obtained on 260 days, the record has been completed by plates from the Cape, Kodaikanal, and Tortosa Solar activity has diminished considerably, but large spots were seen in October, February, and March With the spectroheloscope considerable solar eruptions were observed on Aug 12 and Nov 25, the latter gave an outward velocity of 450 km /sec, which is near the parabolic value

The following are the mean magnetic elements obtained at Abinger in 1930 Decl 12° 24 6 W Hor force 0 18542, Vert force 0 42924, Dip 66° 38 2 The decl is diminishing at the rate of 11½ annually, so that it should vanish a little before the end of the century Magnetic observations are occasionally made at Greenwich in the early morning, when electric trains are not running, these will be continued, as there is an unexpectedly large range in the determinations of decl as compared with the Abinger ones

The following weather records refer to the year ended on April 30, 1931 temperature 50 0°, being 0 5° above the average, highest 92 2° on Aug 28 and 29, lowest 21 0° on Mar 10 There were 55 days when temperatures of 32 0° or lower were recorded, the mean daily movement of air was 289 miles, being 5 miles above the average, the greatest value was 713 miles on Jan 17 There were 1320 hours of bright sunshine or 29 6 per cent of the possible amount The rainfall was 27 94 inches, which is 3 70 inches above the average, on June 18, 2 66 inches fell in 2 hours

Time determinations are now made with a small reversible transit instrument fitted with a travelling micrometer, two Shortt clocks (No 3 and No 11) are used as standards of sidereal time, the progressive increase of losing rate of No 11 still continues The mean time signals are controlled by Shortt No 16 Wireless signals from Paris, Nauen, Annapolis, and Bordeaux are registered automatically, they all agree in being apparently late on Greenwich, the amounts being 0 016 sec, 0 044 sec, 0 039 sec, and 0 033 sec respectively The Annapolis one is corrected for time lag The difference is unquestionably systematic, for out of the 48 monthly means that are printed in the report there are only three that are earlier than Greenwich

Several photographs were exhibited of Eros and neighbouring stars, these were measured for three different purposes The principal research was the solar parallax and the mass of the moon, the second was the light variation, which was plainly visible in the series of images on some of the plates The third was the determination of mean wave length of Eros and the comparison stars, which was effected by placing a grating before the object-glass

A C D CROMMELIN

Messages in Sensory Nerve Fibres and their Interpretation *

BY amplifying the electric changes which take place in the individual nerve fibres it is possible to record the messages which pass from the sense organs to the central nervous system and from the motor nerve cells to the muscles It is found that a series of brief potential changes travel along each nerve fibre, the changes are of fixed intensity and duration, but their frequency varies with the intensity of the excitation Each potential change represents a nerve impulse of the type made familiar by the classical methods of electro-physiology Reasons are given for the belief that all nervous communication is carried out by such impulse messages, and that the impulses, like the electric changes which accompany them, are unaffected by variations in the intensity of the stimulus The general similarity of motor and sensory messages makes it probable that the sensory nerve endings and the synaptic regions of the central nervous system work on a common plan depending on the fundamental properties of excitable cells

The sensory messages which have been most thoroughly investigated are those produced by the muscle spindles Those from the skin receptors are less easy to analyse but are of greater interest to the physiology of sensation At present the most definite results have been obtained from the frog The frog's skin contains receptors which respond to light contact with a brief discharge of impulses travelling in nerve fibres which conduct rapidly A vibrating stimulus gives a series of impulses with the same frequency as that of the stimulus, but discharges of high frequency and long duration from these receptors do not give rise to pain Stimuli which would be likely to cause continued pain give rise to impulses of small action potential travelling in fibres which conduct very slowly (about 1 metre a second)

In the mammal, as in the frog, light touch produces a brief discharge of impulses of large potential conducted rapidly, and firm pressure gives a continued discharge Impulses of smaller potential conducted at slower rates are produced by movement of the skin and persistent discharges often arise from exposed tissues At present it appears that some of these impulses are caused by stimuli which would not necessarily be painful

A comparison of these results with those of Gasser and Erlanger and of Piéron shows that the nerve fibres responsible for pain are not all of the same type, though they are all of smaller diameter than the tactile fibres It is suggested that the rate of reaction and amount of convergence in the sensory pathways are important factors in determining the intensity of sensation, since this must depend on a summation of the effects of discontinuous impulses

* Abstract of the Croonian Lecture delivered before the Royal Society on June 4 by Prof E D Adrian F R S

Fisheries Research at Hull

THE Department of Zoology in the University College of Hull has recently been expanded into that of Zoology and Oceanography From its first establishment it has been intended that there should be co-operation between the Department of Zoology and the fishing industry The Humber ports form the largest fishing centre in the world The Council of the College has now decided to put into operation a scheme of fishery research which is to be organised by Prof A C Hardy A new section will be added to the accommodation of the department and three research biologists will be appointed The capital expenditure will be borne by the College, but the greater part of the maintenance charges will be met by a grant from H M Treasury, which has been made on the recommendation of the Development Commissioners A grant towards the cost has also been made by the Fishmongers' Company, and it is hoped that contributions will be made by the fishing industry itself The scheme of research, which will be carried out in co operation with the Ministry of Agriculture and Fisheries and the Fishery Board for Scotland, and will be co-ordinated with the researches of the International Council for the Exploration of the Sea, concerns the distribution of the North Sea plankton in relation to the movements of fish, particularly the herring

It is the policy of the department to carry out this research not from a single research ship, but from fishing vessels and other commercial ships which are prepared to carry specially designed self recording instruments for plankton and other measurements. It is believed that there are certain important problems connected with our knowledge of the sea and its changing conditions which cannot be solved by using one research ship to cruise over the area concerned, just as a knowledge of the weather cannot be obtained by having one meteorological station moving about from place to place It is proposed to chart in broad outline the monthly movements of the North Sea plankton by the simultaneous use of continuous plankton recorders on a number of scheduled steam ship routes across the North Sea, and to correlate the distribution of the plankton with the concentration of fish as reported by the industry The herring shoals do not always turn up where they are expected, they move their ground from time to time, usually the fishermen can find them, but sometimes they cannot, at any rate in sufficient numbers to make a successful season When, over a period of five years, a knowledge has been gained of the changing distribution of herring food and patches of such organisms as *Phæocystis* and *Rhizosolenia*, which the herring apparently avoid, it is hoped that it may be possible to make forecasts as to the position of the shoals of herring From this work a wider field of investigations should be opened up, including a study of the possible causes underlying the fluctuations in the stocks of different fish

A new continuous plankton recorder suitable for use on commercial ships has been designed, it is an improvement on and a smaller pattern than, the original machine which was first used on the 1925–27 *Discovery* Expedition and was described in NATURE of Oct 30, 1926 It is towed like a paravane behind a ship and continually samples the plankton in the water traversed The plankton is collected on a long banding of fine silk netting which winds into a preservation chamber It is worked from the water by a propeller, the adjustable blades of which allow each of a series of numbered divisions on the moving silk to represent a mile or more of sea The rolls obtained are kept for examination on a special microscope substage

A number of simpler instruments, obtaining a single sample of the plankton for correlation with the catch of herrings, will be used by herring drifters when engaged in fishing

In addition to the research programme, a one year course in oceanography with particular reference to fishery problems is being arranged for post graduate students

University and Educational Intelligence

CAMBRIDGE — The Adams prize (value about £240), which is awarded every two years for an essay on some branch of pure mathematics, astronomy, or other branch of natural philosophy, has been awarded to Mr A S Besicovitch, fellow of Trinity College The subject given out for the period 1929–30 was "The Theory of Almost Periodic Functions"

The Appointments Committee of the Faculty of Physics and Chemistry has reappointed Dr F C Phillips, of Corpus Christi College, University demonstrator in mineralogy

The Vice Chancellor gives notice that the professorship of mineralogy and petrology has been established, and that a meeting of the electors will be held on June 24 The professorship is governed by Statute D and by the regulations which were approved by Grace on April 24, 1931 The stipend of the professor is £1200 a year or, if he holds a fellowship with dividend, £1000 a year

Candidates are requested to communicate with the Vice Chancellor on or before Friday, June 19 No testimonials or references need be sent If a candidate desires to submit any, they should not exceed four in all, and in the case of testimonials, ten copies of each should be sent to the Vice Chancellor not later than June 19

LONDON —The Court of the University has appointed Mr Charles Holden, senior partner of the firm of Messrs Adams, Holden and Pearson, of 9 Knightsbridge S W to be the architect of the new buildings which the University proposes to erect on its site in Bloomsbury, on the north side of the British Museum Mr Holden's task will be a large one When building operations begin, the site will be an island one of more than ten acres, bounded on the south by Montague Place, on the west by Malet Street, on the east by Russell Square and Woburn Square, and on the north by Gordon Square and Byng Place Among the first buildings to be erected will be the Administrative Offices, the University Hall, and the University Library, premises for the Officers' Training Corps, and buildings for the Institute of Historical Research and the Courtauld Institute of Art To these will in all probability be added the London Day Training College, and the Court's programme provisionally includes accommodation for Birkbeck College, the School of Oriental Studies, and the University Students' Union Space will also be reserved for other purposes, among which residential accommodation for students, a faculty club and residential chambers for staff will be considered This building programme will of necessity have to be undertaken in stages, and will take many years to complete, but, with the view of ensuring that, when the work is ended, all the buildings will form part of a dignified and harmonious scheme, Mr Holden is being asked to prepare at once a design for the whole of the site

The following doctorates have been awarded *D Sc Degree in Physics* to K R Rao (Imperial College—Royal College of Science) for a thesis entitled "Analysis of the Line Spectra of certain Elements of the Third, Fourth, and Fifth Groups" (*Proc Phys Soc*, *Proc Roy Soc*, and NATURE, 1929) *D Sc Degree in Zoology* to N A Mackintosh (Imperial College—Royal College of Science) for a thesis entitled "Southern Blue and Fin Whales" (Camb Univ Press, 1929) *D Sc (Economics) Degree* to D Mitrany (London School of Economics) for a thesis entitled "The Land and the Peasant in Rumania" (Oxford Univ Press, 1930) *D Sc Degree in Mathematics* to G F J Temple for six published papers on "The Quantum Theory of the Spinning Electron"

MANCHESTER —The Manchester City Council is again offering a number of scholarships tenable in the Faculty of Technology of the University Successful candidates are required to follow a full time course leading to the degree of bachelor of technical science in the College of Technology, and matriculation or its equivalent is an essential qualification For students who have been engaged in industry, and who have attended part time day or evening classes, the scholarships are of the value of £100 per annum, while for students leaving secondary or central schools the value is £60 Both classes of scholarships are tenable for three years

---

THE Science Scholarships Committee of the Royal Commission for the Exhibition of 1851 has made the following appointments to Senior Studentships for 1931 Ernest C Childs for research in physics (London) Philip S H Henry, for research in physical chemistry (Cambridge), H S W Massey, for research in physics (Cambridge), Brian H C Matthews, for research in physiology (Cambridge), William V D Hodge, for research in mathematics (Bristol), and Alexander R Todd, for research in organic chemistry (Glasgow)

Birthdays and Research Centres

June 12, 1851 —Sir OLIVER LODGE, F R S, late Principal of the University of Birmingham and formerly professor of physics in University College, Liverpool

The subject which chiefly interests me is a verification of the theory that requires a flow of ether along magnetic lines of force thereby presumably affecting the velocity of light in a magnetic field The effect to be observed is, I reckon, extremely small, and would require a Fizeau interferometer with a long path in an exceptionally intense field, though the field need only last for such fraction of a second as would enable interference bands to be photographed My own experiments of 1897 were on right lines, but their power was quite insufficient To get a result, a combination of the optical skill of the late Prof A A Michelson with the intense magnetic fields produced by the genius of Dr Kapitza would seem to be necessary, and perhaps also engineering and financial aid such as the late Sir Charles Parsons at one time contemplated A positive result, if it could be attained, would be of the greatest interest and would break the prevailing monotony of negative results yielded by all recent attempts at bringing the ether to book and restoring it to its inevitable place in the scheme of Nature

June 14, 1857 —Prof J E MARR, F R S, fellow of St John's College and lately Woodwardian professor of geology in the University of Cambridge

More attention might usefully be given to the deposits containing human relics, particularly from the geological point of view This is being done, but much more is required, for, though the task of establishing time sequences and then correlating beds in different areas has been carried some way, that of restoring the physiographies of various areas in the different periods is still in its infancy

When this important work has been carried out systematically and in detail, it will aid materially in the much greater task of establishing the history of the physical conditions under which deposits were formed, epoch after epoch, during the geological ages —a work which has not, during recent years, received the attention it requires

June 14, 1877.—Prof. R. WHYTLAW-GRAY, F.R.S., professor of chemistry in the University of Leeds.

At the present time, I am much interested in developing a buoyancy microbalance of the Aston type so that it can be used for comparing the densities of gases to a high degree of accuracy even at low pressures. This method eliminates many sources of error inherent in the classical methods, and it is hoped to obtain with its help reliable values for the chemical atomic weights of a number of elements.

At the moment we are interested in the atomic weight of carbon, which on account of the presence of the isotope C^{13} must be slightly greater than the mass spectrograph value of 12.003. Data of sufficient accuracy from several gases should enable an estimate of the proportions of the two isotopes to be made.

Other researches, in which I am interested and which are being carried on by colleagues and collaborators in my section of the Department of Chemistry here, include investigations on solid phase reactions, the electrical character of smokes, the nature of the suspended impurities in air, and the vapour pressures of slightly volatile solids.

June 15, 1851.—Dr. E. H. GRIFFITHS, F.R.S., formerly general treasurer of the British Association, and president in 1906 of Section A (Mathematics and Physics) and in 1913 of Section L (Educational Science).

I regret to state that I am not engaged in any scientific work at the present time. For many months I have been suffering acutely from arthritis, so much so that I am unable to write.

For several years past, I had proposed an investigation into the specific heat of gases at high temperatures. As it is now impossible for me to undertake such an inquiry, I hope that some younger and more able man will attack this difficult subject.

June 18, 1858.—Prof. A. R. FORSYTH, F.R.S., emeritus professor of mathematics in the Imperial College of Science and Technology.

In differential geometry, the expression

$$ds^2 = Edp^2 + 2Fdpdq + Gdq^2,$$

where E, F, G are functions of parameters p and q, represents the general arc on any surface in flat triple space, subject to three known conditions involving the coefficients in the associated quadratic differential form for the curvature of a superficial geodesic. An arc on any surface, in any domain whether flat or curved, is represented by the same formal expression. It is important to obtain the conditions which must be satisfied in order that the represented surface may exist: either (i), in a given curved triple space, itself existing in a flat space of four dimensions; or (ii), in a flat space of four, but not fewer than four, dimensions.

June 19, 1897.—Mr. C. N. HINSHELWOOD, F.R.S., fellow of Trinity College and lecturer in chemistry in the University of Oxford.

Investigations now in progress are connected with the mechanism of chemical changes in gases, with surface catalysis, and with the relation between reactions in the gaseous state and the corresponding changes in solution. Among gas reactions, oxidation processes are being specially studied at the moment, particularly with reference to the theory of 'chains', and the nature of the curious explosion phenomena encountered in such systems as hydrogen-oxygen mixtures is being examined. The influence of negative catalysts and of surfaces on these effects is gradually yielding information. Some of the earlier work on reactions depending on simple molecular collisions is being extended in the light of more recent knowledge.

Societies and Academies.

LONDON

Physical Society, April 17.—E. G. Richardson: Edge tones. If a fluid leaves an orifice as a jet and strikes an edge, two vortex streets are formed on each side of the wake and maintain the jet in pendulation at a definite frequency. The tones so produced are examined from theoretical and experimental points of view, and relations connecting the frequency with (*a*) velocity, (*b*) distance from orifice to edge, (*c*) width of orifice, (*d*) form of the orifice, are tested. All the features of the phenomena can be explained in terms of the hydrodynamics of a viscous fluid, without compressibility being postulated in addition.

Geological Society, May 6.—C. A. Matley: The geology of the country around Mynydd Rhiw and Sarn, South Western Lleyn (Carnarvonshire). The region described includes a ridge of high ground which attains a height of 994 feet on Mynydd Rhiw. Much of the lower ground is covered by glacial drift. The sedimentary rocks are of Arenig and Lower Llanvirn age, and range from the Extensus Zone to a high part of the Bifidus Zone. The local base of the Arenig is found at only one small exposure, and there it rests on the mica-schists (Penmynydd Zone) of the Mona complex. In the Hirundo Zone, and extending into the Bifidus Zone, is the Rhiw volcanic group, in which four lava flows have been found, as well as rhyolitic ashes and ashy sediments. Intrusive rocks are abundant, and range in composition from acidic to ultrabasic; they are linked genetically by their common richness in soda, and can be considered, with the volcanic rocks, as varied members of one spilitic suite. They include the Sarn granite, numerous albite-dolerite sills, and the coarser grained intrusions of picrite, proterobase, and hornblende dolerite which are found only at the top of the sequence. These intrusions are discussed, and the possibility considered that they may be a single sill or laccolith broken and displaced by faulting.—E. Greenly and P. G. H. Boswell: An Ordovician grit from Anglesey, with its bearings upon palæogeography, and upon the tectonics of the Mona complex. The grits at the base of the Arenig beds at Berw, near Holland Arms, are exceptionally rich in heavy minerals. Garnet, sphene, and epidote are abundant, as are ilmenite, biotite, and white mica. The felspars are orthoclase, albite, and olioclase. There are also small pebbles of Penmynydd Zone mica schist, Gwna green schist, and many of granitoid acid gneiss. The evidence both of minerals and rock fragments points to the acid gneisses as the principal source, with contributions from the Gwna beds and the acid members of the Penmynydd Zone. The evidence furnishes unexpected confirmation of a tentative hypothesis, already put forward, that the gneiss of Holland Arms, instead of having been brought up from below, has been brought down from above, on an infold of the Newborough slide, from the inverted upper limb of the Bodorgan recumbent fold.

CAMBRIDGE

Philosophical Society, May 18.—J. D. M'Gee: The charges of recoil atoms in relation to surface conditions. The charge carried by α ray recoil atoms of radium *D* escaping from a source of radium *C* is one positive unit when the source is deposited on a clean nickel or platinum surface. The direct method of collecting a beam of particles from a source in a Faraday cylinder and comparing the charges received by it, when the recoil atoms and α rays were successively eliminated from the beam, was used. The charge carried by a

recoil atom can then be compared with that carried by an α particle The charge carried by a recoil atom is influenced by the work function of the surface from which it escapes The cause of earlier conflicting results has been traced to the presence of high energy ions —**J E I Cairns** Conduction along thin metallic films Experiments on the electrical conductivity of thin films of cadmium and nickel showed good agreement with the theory of Ehrenberg and Honl, if it be assumed that for very thin films aggregation of the metal into small crystals with intervening gaps occurred The ageing of cadmium is anomalous and can only be attributed to internal rearrangement among the crystal aggregates forming the film Nickel, however, shows regular behaviour, and in every case after deposition its conductivity decreased, usually reaching a steady value in 4–5 minutes Composite films consisting of a low work function metal upon a higher one gave interesting results —**N Feather** Concerning the success of the absorption method of investigating the high velocity limit of continuous β ray spectra Simple absorption measurements, interpreted on the basis of the range energy relation for homogeneous particles, lead to satisfactory estimates of the maximum energies represented in the continuous spectra of many β ray bodies Calculations show that this empirical result follows from the known form of the absorption curve for homogeneous particles, the known relation between extrapolated range and energy for such particles, and the most general considerations regarding the characteristics of measuring instruments usually employed —**P S H Henry** The specific heats of diatomic gases A short summary is given of the theory of the specific heats of diatomic gases on classical and on quantum mechanics This is followed by a description of a flow method of measuring specific heats due to P M S Blackett, and some results obtained with it for air, nitrogen, oxygen, and methane between 20° C and 350° C are shown These disagree markedly with the results of sound velocity measurements, and are in closer, though not exact, accord with theory —**E L C White** A method of continuous observation of the equivalent height of the Kennelly Heaviside layer Wireless 'echoes' from the Heaviside layer are observed in the form of a stationary pattern on a cathode ray oscillograph screen, from which the height of the layer at any instant is seen at a glance

EDINBURGH

Royal Society, May 4 —**L R Cox** A contribution to the molluscan fauna of the Laki and Basal Khirthar groups of the Indian Eocene The paper describes the molluscan fossils collected by Lieut Col L M Davies from the Laki group (Lower Eocene) and lowest beds of the Khirthar group (Middle Eocene) of several districts in north western India, supplemented by material from other collections in the British Museum The work of d'Archiac and Haime (1854) on mollusca from these beds is also revised Forty five gastropod and 54 lamellibranch species, mainly from the Laki group, are described, 16 gastropods and 7 lamellibranchs being new to science Few species range up from the underlying Ranikot group, but this may be due partly to a change in facies The difference between the faunas of the Laki and Khirthar groups is less pronounced, many species occurring in both series Thirty five of the gastropods and 28 of the lamellibranchs described are known only from India, and the gastropods include certain genera not known from other countries, one genus is described as new Several of the species recorded occur also in southern Europe, and one or two as far afield as Jamaica; a few very widespread forms occur also in northern Europe The affinity of the fauna with that of the Eocene of Egypt and, more especially, of Somaliland is closer than with that of Europe —**H Boschma** On the identity of *Sacculina triangularis* and *Sacculina inflata* Specimens of *Sacculina triangularis* (Anderson, 1862) on *Cancer pagurus* from the Firth of Forth were examined, and it is concluded that *S triangularis* is identical with *S inflata* (Leuckart 1859) on *Hyas coarctatus* The valid name of the species is therefore *S inflata* This species differs from *S carcini* by constant specific characters —**S Williams** An analysis of the vegetative organs of *Selaginella grandis* Moore, together with some observations on abnormalities and experimental results The plant of *S grandis* consists of a dichotomously branched shoot showing a basal decumbent portion bearing rhizophores, an erect dichopodial axis, and a distal fan shaped region with middle shoots The apex of the stem possesses two four sided initial cells Branching is dichotomous and at each branching an angle meristem is formed The latter gives rise to rhizophores at the basal branchings and to middle shoots at distal branchings Roots arise endogenously in the tips of the rhizophores The root apex has three initials a calyptrogen, dermatogen, and a common initial for plerome and periblem Abnormal developments of the middle-shoot and proliferations of vegetative and cone apices occur, and it is also possible to obtain such deviations from the normal by experimental methods The general morphology of the plant is discussed and it is concluded that the rhizophore is an organ *sui generis*, indifferent in nature —**L M Milne-Thomson** Operational solution of the homogeneous linear equation of finite differences by generalised continued fractions Given a homogeneous linear finite difference equation of the second order, a continued fraction, constructed from the coefficients, can be made to yield a solution of the equation in terms of the initial values of the dependent variable By associating a suitable operator with the co-ordinates of a point in space of m dimensions, the notion of continued fractions is generalised to this space and an operational solution of the linear difference equation of the mth order is obtained —**Dr A C Aitken** Further numerical studies in algebraic equations and matrices The paper follows up a similar paper of five years earlier, simplifying the former methods by using the dual properties of symmetric functions, and proposing now to evaluate all the roots of an equation by subjecting the coefficients to a uniform repeated process of cross multiplication and division The process is a special case of the method of finding the latent roots of a matrix by raising the matrix to high powers The numerical work suggests a theorem in matrices which is demonstrated, namely, that the rational canonical form of a matrix can be transformed at once into the classical irrational canonical form, the transforming matrix being of alternant type —**D Meksyn** Electromagnetic phenomena in a uniform gravitational field The radiation of an electron moving freely in a uniform gravitational field is evaluated The electromagnetic equations can be rigorously solved for this case The result obtained is Larmor's value for the rate of radiation The calculation is based on Poynting's theorem and the geodesic propagation of light The result obtained shows that the principle of equivalence can be applied to the evaluation of radiation, if allowance is made for the quantum properties of light.

DUBLIN

Royal Irish Academy, April 27.—**J K Charlesworth** A tentative reconstruction of the successive margins of the quaternary ice sheets in the region of the North Sea. The outer limit of the British drift is composite During the Saale-upper older drift period the ice margin over the North Sea was cusp-shaped. During the period of the newer drift of Britain—

Brandenburg or Warthe stage of north-west Europe—when the edge of the Scandinavian ice lay off the west coast of Norway, the British ice formed an independent piedmont mass over the western half of the North Sea.—**A. Muskett, E. N. Carrothers, and Hugh Cairns**: Contributions to the fungus flora of Ulster. A report of work carried out from 1923 to 1931, records 312 species and 9 varieties new to Ulster, thus bringing the total up to 916, besides adding 78 species and one variety to the Irish flora. Short notes are included for each species, giving details of place and date for each record.—**K. G. Emeléus and Olive Hall**: The spectrum of the cathode glow in nitrogen and other gases. The arc spectrum of nitrogen (N I) appears strongly in the light of the cathode glow of a low voltage d.c. glow discharge, in spite of the fact that it is otherwise somewhat difficult to excite. An explanation of this is offered, based upon Kallmann and Rosen's work on interchange of charge between slow positive ions and neutral particles, which also accounts for the cathode glow spectrum in a number of other polyatomic gases and mixtures, but fails to explain adequately the thickness of the cathode glow. The bright flecks which form at points where a discharge strikes to the rear of the cathode have been shown to be local plasma type discharges.

Royal Dublin Society, April 28.—**W. R. G. Atkins**: Some experiments on the accuracy obtainable with gas filled photoelectric cells. Even using N. R. Campbell's method of postglow discharge measurements the results obtained with a thick film cæsium cell were unreliable at high voltages, though reasonably accurate for low illumination at 12 volts anode potential without glow discharge. With a G.E.C. potassium cell the sensitivity afterglow discharge decreases at first by 2·3 per cent per minute. Measurements made immediately after the discharge agreed to within 2 per cent with current about 5 μa, anode potential 59 volts; agreement was not quite so good at 166 volts.—**P. A. Linehan and S. P. Mercer**: A method of distinguishing certain strains of New Zealand perennial rye grass (*Lolium perenne L.*) by examination of seedlings under screened ultra violet light. Seedlings of the valuable Hawke's Bay district New Zealand perennial rye grass may be distinguished from the inferior strains from other districts by growing them on white filter paper and examining under screened ultra violet light. Only a very small percentage of the Hawke's Bay seedlings render the paper fluorescent, whereas a large percentage of seedlings of other varieties do so.

CRACOW

Polish Academy of Science and Letters, Jan. 5.—**Mlle. M. Kaczyńska**: Retarded luminescence in carbon dioxide. The time during which the light persists in the observation tube may reach 8 sec.; this time diminishes as the pressure of the gas in the tube increases.—**A. Skapski**: The charcoal adsorption of a weak electrolyte in saline solutions.—**E. Kurzyniec**: Study of the system calcium bismuth. From the thermal analysis of calcium bismuth alloys it is concluded that the system contains two components, Ca_3Bi_2 and $CaBi_3$.—**K. Dziewoński and L. Sternbach**: Researches on the ketones, acetyl derivatives of the bromonaphthalenes.—**W. Swietoslawski, A. Piltz, and F. Kraczkiewicz**: Methods of synthesis of sulphonic derivatives of naphthoquinonechlorimines.—**J. Elkner**: Researches on the basophil conjunctive tissue in the human larynx.—**F. Rogoziński**: Experimental rickets. Comparison of some diets producing rickets.—**L. Sitowski and St. Runge**: *Spiroptera microstoma* in the stomach of an embryo of the horse aborted at seven months.

Royal Society of Medicine (Orthopædics Section) (at Oxford)

PUBLIC LECTURES.

FRIDAY, June 12

London School of Hygiene and Tropical Medicine (Public Health Division), at 5 —Sir Thomas Legge Industrial Poisonings

TUESDAY, June 16

London School of Hygiene and Tropical Medicine (Public Health Division), at 5 —Sir George Buchanan International Hygiene

Institute of Pathology and Research (St Mary's Hospital W 2), at 5 —Dr B Hart The Causation of Neurotic Disorders

WEDNESDAY, June 17

Faraday Society (at Royal Institution) at 5 30 —Dr R I Mond Michael Faraday (Spiers Memorial Lecture)

FRIDAY, June 19

London School of Hygiene and Tropical Medicine (Public Health Division), at 5 —Sir Thomas Legge Industrial Poisonings

CONFERENCES.

June 10 to 13

South Eastern Union of Scientific Societies (at Winchester).

Friday, June 12 (Geological Section), at 10.30 A M —Prof H L. Hawkins Some Generalisations on the Nature, Deposition, and Palæontological Implications of the Chalk

At 11 45 A M —F H Edmunds The Relation of Soil and Geology of the Weald

(Zoological Section) at 10 30 A M —J F Marshall The Stereoscopic Photomicrographs of Fossil Insects exhibited in the Congress Museum

At 11 A M.—H Main Insect Observations Underground

At 12 —E A Martin The Making of Pearls

At 8 P M —W P D Stebbing A Motor Tour of 7500 miles from the Transvaal to Western Uganda (Public Lecture)

Saturday, June 13 (Regional Survey Section), at 11 A M —H J E Peake Archæological Surveys.

June 15 to 18

International Union for the Scientific Investigation of Population Problems (at Royal Society of Arts) —The first three morning sessions will be devoted to official business, and the afternoon sessions and the whole of June 18 to reports and papers relating to the work of the Union Commission 1 (Population and Food Supply) reports on the first afternoon, Commission 2 (Differential Fertility) on the second afternoon, and Commission 3 (Vital Statistics of Primitive Races) on the third afternoon Papers to be read on these afternoons and those for June 18 include studies on Differential Fertility in Stockholm, the Birth rate and Population of the United States, and Vital Aspects of a Chinese Family Population during six hundred years, general papers on Population Theory and Human Biology, and Experimental Work on Mice Populations

SUMMER MEETINGS.

June 11 to 13

Newcomen Society for the Study of the History of Engineering and Technology (at Sheffield).

June 17 to 19

Institution of Water Engineers (at Harrogate)

Wednesday, June 17 (at Hotel Majestic), at 10.30 A.M —H Prescot Hill Presidential Address.

E. Sherman Chase Modern Aspects of Water Purification

C. M Saville Modern Dam Construction.

Afternoon —F W Macaulay The Construction of Modern Water Mains.

H A. P Hetherington The Sinking of Borings.

Progress and Prejudice.

SIR ARTHUR KEITH'S rectorial address on "The Place of Prejudice in Modern Civilisation", delivered on June 6 to the students of the University of Aberdeen, bore challenge in its title and in its matter was boldly provocative He was conspicuously courageous in attacking the gravest of the world problems of to-day—the future of international relations—from the point of view of the thorough going evolutionist Drawing on his studies of racial evolution from prehistoric times onward, he gave it as his considered opinion that race prejudice has to be given a recognised place in modern civilisation He postulated a continuance of tribal rivalry and competition as an essential of progress in the future

Sir Arthur's address teemed with phrases which almost charm acquiescence by their terse epigrammatic quality "Without competition mankind can never progress, the price of progress is competition", "Race prejudice and national antagonism have to be purchased, not with gold, but with life", "Nature keeps her human orchard healthy by pruning—war is her pruning hook" The last metaphor was not slow in moving criticism A correspondent in the press at once pointed out that a pruning hook removes dead and useless wood while war does the reverse Arboricultural experts may differ as to the exact function of a pruning hook the biologist and the demographer will agree as to the function of war in helping to preserve the equilibrium of population, environment, and food supply The anthropologist, too, would be at no loss for examples to show that the abolition of tribal war under white administration has had an adverse effect in removing checks on an excessive growth of population, as in parts of South Africa, or by eliminating the zest of life and opening the way to racial decay, as in Melanesia The price is undoubtedly heavy, and the results of the last war make it imperative that we should count the cost In so doing, no side of scientific argument may be neglected If Sir Arthur Keith's dicta, when torn from their context, seem needlessly ruthless, it is a ruthlessness which is due to the facing of facts, for Nature sacrifices the individual that the race may survive, and so in the long run does Society

No one with any sense of history could have believed that the War was "a war that would end war" Yet a generation has grown up since 1918 of which a considerable section believes that war in future will be averted by the growth of public

opinion Another section, and that too very considerable and far from being entirely of the post-War generation, looks to internationalism to act as a preventive Not the whole of this latter group rests its hope on a sentimental idealism For some its end is to be attained through the application of scientific principles They would weld the peoples of the world into a single tribe But what does this imply? As Sir Arthur puts it, "To obtain universal and perennial peace—the price is the racial birthright that Nature has bestowed on them" All peoples, black, yellow, brown, and white, must pool their blood In other words, intermarriage and the elimination of the present distribution of the peoples of the earth into races must produce a world populated by closely related hybrids, so closely related, in fact, that strife, in theory, becomes impossible

Passing over the undoubted fact that members of the same family have been known to quarrel, we may point out that the facts of miscegenation in man are at present sufficiently obscure to warrant some hesitation at cross-breeding on such a colossal scale, especially as knowledge at the present moment does go so far as to suggest that some crosses, at least, do entail a certain amount of degeneration from the higher of two standards where there is any considerable difference between the two But even granting that future research in such a subject, for example, as the distribution of the blood groups, should prove competent to suggest lines upon which cross-breeding might be practised on a large scale without the danger of wholesale deterioration, a long time would have to elapse before a scientifically directed control would be able to regulate marriage as efficiently as racial prejudice has succeeded in barring marriages by state legislation in the United States of America, when one of the would-be contracting parties can be shown to have a strain of colour inherited from even a remote ancestor of many generations back

The colour problem is the most momentous of all those into which the question of race prejudice enters, and it is no exaggeration to say that the future of our civilisation depends upon its successful solution Clearly, however, Sir Arthur Keith had more directly in view the urgent problem of the relations which are to subsist in the nearer future between the nations of western civilisation

Whatever may be the ideals of the internationally minded, it is impossible to evade the fact that race prejudice is deep seated, and that, owing to its survival value, it has been, and will continue to be, paramount As Sir Arthur phrased it, the prehistoric world in which man's tribal heart was fashioned was organised by Nature for the evolution of new and better races of mankind The 'tribal heart' still beats to-day It is the functioning of the strongest instinct which has been implanted in man, working through the group of which each individual is a member—the instinct of self-preservation

It would appear that the evolutionist has but cold comfort to offer the apostle of peace who pins his faith to the obliteration of race prejudice and national antagonisms On an evolutionary view of human progress, the attempt to form a League of Nations at the present juncture in the world's history is a break in an ordered advance It departs from the line of racial evolution and social development alike We must view race not as static but dynamic In the conditions of human society the mingling of racial types produces endless variation The nation represents a stage in racial evolution in which various racial strains—for anthropologists are agreed that there is now no such thing as a pure race—are being moulded so as to verge towards a common type, varying more or less widely in individuals, as in England, and closely bound by a common language and common institutions

Yet it is evident that the world is becoming ripe for change When we pass in review the history of humanity in the light of the teaching of social anthropology, it becomes manifest that there is in social institutions a regular progression and a constant movement to extend the feeling of solidarity over an ever increasing range from family to kin, from kin to tribe, and so forth, until we come to the nation and the Empire Now we are approaching the battle of the greater units For nearly a generation there have been movements in various parts of the world to burst the bonds of nationalism and to reach out to a greater unity in Pan-Turanian, Pan-Moslem leagues, and the like The Union of Soviet Republics, not content with the bounds of the old Russian Empire, seeks in time to embrace the workers of the world The League of Nations itself is symptomatic of this urge, but if the evolutionary view be right, it asks too much at the present stage of human development If Sir Arthur Keith is correct in his view of the trend of racial evolution, in regarding the English speaking peoples as the future custodians of peace, so far as they represent an advance in the evolutionary scale, he has the support of science and of sentiment alike

A Theory of Money

A Treatise on Money By John Maynard Keynes Vol 1 *The Pure Theory of Money* Pp xvii + 363 Vol 2 *The Applied Theory of Money* Pp viii + 424 (London Macmillan and Co, Ltd, 1930) 15s net each vol

MR KEYNES'S "Treatise on Money", the fruit of his study and reflection up to date on the part played by currency and credit in contemporary civilisation, is the most important work on monetary theory published since the War, certainly in England and probably throughout the world Its two volumes, entitled respectively "The Pure Theory of Money" and "The Applied Theory of Money", are divided into seven books The first book is concerned with essential definitions, the second investigates what the value of money really means, and how its fluctuations may best be measured, the third and fourth books—which contain the heart of Mr Keynes's theory—deal with the factors which determine the value of money and the dynamics of changing price levels, the fifth and sixth are taken up with a study of the statistical and non-statistical data bearing on changes in the quantity of money and its velocity of circulation, in the volume of production and trade, and in the rate of investment, while the seventh and last book contains Mr Keynes's proposals for the practical reforms which he would like to see the ultimate monetary authorities of the world adopt in order to achieve the objectives at which, in his opinion, monetary policy should aim

To state Mr Keynes's theory both briefly and accurately is impossible A technical subject demands technical terms whose precise definition cannot be short But subject to the *caveat* that almost every expression used in the quotation which follows requires elaboration, the kernel of his doctrine is that "the price level of output depends on the level of money incomes relatively to efficiency, on the volume of investment (measured in cost of production) relatively to saving, and on the 'bearish' or 'bullish' sentiment of capitalists relatively to the supply of savings deposits in the banking system" (vol 2, pp 345-6) In this statement it is implied by Mr Keynes's earlier chapters (*a*) that windfall profits or windfall losses (themselves highly complex concepts) are excluded from money incomes and from savings, (*b*) that investment represents real additions to the capital stock of the country or countries concerned, and (*c*) that savings deposits are true savings deposits and not merely the funds labelled by banks with this name for various extraneous reasons, while (*d*) 'bearishness' denotes the excess of the public's desire to hold liquid claims to cash rather than securities which are expected to decline in value over the amount of cash available for this purpose in the form of savings deposits, and 'bullishness' means the converse

In at least three respects this new theory of money marks a distinct advance over the principal alternative theories which have hitherto held the field First, it is excellent that so eminent an economist should have abandoned the arid rigours of the unabated quantity theory of money and exposed the barrenness of the algebraic identities in which that theory is usually formulated In the second place, the emphasis placed on the importance of the relationship to the value of money between savings and investment on one hand and the volume of consumption and investment goods produced on the other, opens fertile and promising avenues to further investigation Lastly, by demonstrating that modern banking plays a dual rôle, acting both as the supplier of current cash for depositors and as the purveyor of short loans mainly for working capital for industrial and trading borrowers, the new theory straightens out an old confusion and throws into relief an element which can and will be utilised in the course of time to guide and control economic activities much more successfully than they are guided and controlled to-day

Nevertheless, Mr Keynes's analysis as a whole appears to the present writer to be neither conclusive nor satisfactory, and to him at least it seems to break down in several vital places For example, Mr Keynes claims to have proved that if investment exceeds or falls short of savings, profits or losses (in his sense) must respectively arise in respect of output as a whole At the crucial stage in his proof, however, he apparently abandons the analysis and formulæ he has taken pains to establish in the preceding pages, and tacitly introduces a new set of assumptions which either imply a novel (and wholly undeveloped) theory as to the relationship between new savings and dealings in existing securities, or else boil down to the doctrine that additional supplies of bank money injected into the economic system tend to raise prices, and conversely The former alternative—a novel theory about savings and securities—is too embryonic to be susceptible of criticism the latter alternative—the addition or withdrawal of bank money—assumes the conclusion in the

premises, and is an obvious truism, but one which leaves the relationship which he alleges to exist between investment, savings, and profits (or losses) totally unproved Although the exposition (cf vol 1, chap 10, section (iii), and particularly p 145) is so inordinately obscure that it is practically impossible to arrive at Mr Keynes's exact meaning, even the most sympathetic reader cannot escape the uncomfortable feeling that one of the corner stones of the entire "Treatise" is insubstantial and the underpinning shaky

Similar defects appear elsewhere, especially in Book iv, on the dynamics of the price-level Here rigorous demonstration is impossible in the nature of things, and Mr Keynes is thrown back on the several probabilities of various alternatives The argument is extremely difficult to follow or to assess, but its upshot is a description of the genesis and development of a credit cycle which at best is ingenious and plausible but which can scarcely claim to be comprehensive or final And when Mr Keynes passes from his theoretical analysis to his practical conclusions, one feels that the reforms he proposes rest on far too uncertain an analytical ground work for them to be acted upon without much closer and more careful examination by the practical men who would have to work them than they have yet received

One further observation may perhaps be permitted Here, devoting itself to the analysis of a subject vital to the very well-being of modern industrial civilisation, and backed, moreover, by a pen of superb literary skill and facility, is a mind as brilliant, as powerful, and as subtle as any mind that has ever been occupied with economic subjects Yet the result of its labours, prolonged over years, is inconclusive and in many respects disappointing Why should this be? Can it be that somehow Mr Keynes, for all his gifts, has just overlooked the philosopher's stone? Or is it that there is no philosopher's stone at all, that the technique of quasi mathematical analysis breaks down when applied to monetary affairs, that in its modern monetary studies the Cambridge school of economists, the most distinguished and honoured modern representative of which is before us, has been exploring not a broad highway but a blind alley? Mathematics, provided it is given the right abstractions to manipulate, has proved itself by results to be the most powerful instrument of thought mankind has yet devised But if the mathematical method is to succeed, it must start off with the right abstractions, and if it begins with the wrong ones, then all that emerges is a will o'-the wisp pseudo science such as astrology Can it be that modern monetary theory has started off with the wrong abstractions? Or are the initial abstractions right enough so far as they go, but too fragile to support the towering fabric of theory which has been erected upon them?

By far the most interesting, freshest, and most instructive sections of Mr Keynes's book are those in which he examines the too scanty existing facts which throw light on the actual movements of various monetary and non monetary elements in economic life Whatever answer different people may return to the questions just asked, there can be no doubt at all that what monetary science now requires is further and more intensive study of the facts now available, and, as Mr Keynes earnestly pleads, more facts supplied by bankers and others for economists to study Until the facts which are urgently needed have been supplied and analysed much more thoroughly than to-day, not even Mr Keynes's genius can reduce the intricacies of this theory to the simple and (where possible) quantitative propositions which alone the common man can understand and utilise in the conduct of practical affairs JULES MENKEN

'Organismal' Conception of Development

The Interpretation of Development and Heredity a Study in Biological Method By Dr E S Russell Pp vi + 312 (Oxford Clarendon Press, London Oxford University Press, 1930) 15s net

IN some branches of biology the relevant data can be pieced together without the aid of any very comprehensive conception of the structure or potentialities of the living organism The study of animal development, on the other hand, constantly provides facts which require, for their interpretation, a definite conception of broad biological principles The developing embryo has potentialities often only revealed in the laboratory, and not infrequently it exhibits, in a striking manner, the subordination of parts to the requirements of the organism as a whole To state that the activities of an organism are something more than an integration of the activities of all its parts, is perhaps a truism, but in Dr Russell's pages it is the central theme of an extremely interesting and careful argument which leads to the establishment of the organism as the only fundamental and valid unit in biology If we accept this conclusion, we reach what the author calls the 'organismal' conception of development, which gives us "rules of method for

the study of living things and their parts without implying any mysterious 'action of the whole' on those parts" We can "accept the simple facts of observation that the organism acts as a whole and that the activities of its parts are subordinated to and co-operate in whatever the organism as a whole is doing at the moment of observation It is from this simple and objective point of view that we must regard the relation between the organism and its cells and energids"

The author's position is, in a sense, impregnable All attempts to portray the facts of development against a background of physics and chemistry have so far failed, whilst the conception of developmental organisers has done much to strengthen the attack on current materialism Dr Russell develops the attack with vision and with vigour He does not stand alone We read, with a feeling of security, that "many of the necessary concepts of 'organismal biology' are in use by biologists especially of the older and sounder tradition", they only require freedom from "any tinge of materialism that may cling to them" Those who feel that they are old enough and sound enough will read Dr Russell's sentence of death on the 'gene' without a quiver of regret, whilst his rejection of the analytical principles which dominate the sciences of physiology and biochemistry will be a timely warning to irresponsible youth All units, except the organism itself, must be swept away if we are to retain an adequate conception of development Molecules, enzymes, genes, chromosomes, cells, and organs all play their part and all are legitimate objects of study by those who are not primarily interested in the most fundamental truths of biology they are no more than the individual words of a sentence—the real meaning of which lies outside the individual components Dr Russell's argument is vigorous and stimulating, it is set forth with scholarly judgment

Most biologists are probably willing to admit that some type of 'organismal' outlook provides a deeper insight into the problems of development than does any other theory, but it is not clear how this conviction leads to the discovery of new facts Theories are ephemeral, facts remain, and it is as a working hypothesis that Dr Russell's conclusions must stand or fall In the meantime, his book will stimulate thought and suppress ultra-materialistic dogma, and this in itself is a very real contribution to biology

It is not difficult to criticise adversely selected passages from a work which not only defines the point of view of its author but also of most of the more eminent biologists of the past Some may think that the author's conception of the chomosome theory of inheritance is an inadequate representation of the established facts, and it may be that when Dr Russell is most vigorous he is least sound Others may be unconvinced that the analytical method is obsolete or unreliable There may even be some who will fail to read the first three chapters without a yawn Those, however, who are not unduly prejudiced in favour of materialism will read the whole book with pleasure, and congratulate its author with more than usual sincerity

J GRAY

A History of Elementary Mathematics

Geschichte der Elementar-Mathematik in systematischer Darstellung mit besonderer Berücksichtigung der Fachwörter Von Dr Johannes Tropfke Band 1 *Rechnen* Dritte, verbesserte und vermehrte Auflage Pp vii + 222 (Berlin und Leipzig Walter de Gruyter und Co, 1930) 12 gold marks

IT is a remarkable testimony to the excellence of this work that a third edition should have been called for within nine years of the issue of the first volume of the second edition (1921) The first edition, in two volumes, appeared in the years 1902 and 1903 and contained about eight hundred pages The second edition was published in seven parts or volumes (1921–24) and ran to nearly thirteen hundred pages in all, the increase being due to the incorporation of the results of new researches into the history of mathematics carried out in the meantime The first part of the present edition contains 222 pages, as compared with the 177 pages of the first part of the second edition, which again shows that the author has included a large amount of fresh material

The preface to the first edition described the plan and intention of the work There were previously available three volumes of the monumental work of Moritz Cantor, the first attempt in recent times to concentrate in one book the vast material existing in earlier histories which had become antiquated (Heilbronner, Montucla, Kastner, Arneth, etc), and in a multitude of scattered articles dealing with separate questions But the great scope of Cantor's undertaking precluded him from entering into great detail, and one effect of its publication was to call forth a number of new works, some of which helped to fill up gaps, while others took the form of histories of separate subjects, for example, Braunmühl's "History of Trigo-

nometry" The strict chronological order followed for the most part in Cantor's work constituted a great difficulty in the way of the reader who wished to inform himself on any particular point at short notice, since the information had to be laboriously gathered together out of a number of different chapters in the book, with the help of the index For a reference book, therefore, which should enable a student to get light on this or that point without loss of time, a systematic arrangement according to subjects is infinitely preferable, and Tropfke's book is written from this point of view

The seven parts of the second edition divide the subjects thus (1) Calculation (numeral systems, whole numbers and fractions, arithmetical operations etc) (2) general arithmetic (including algebra, logarithms, theory of numbers), (3) proportions and equations (4) plane geometry (5) plane trigonometry sphæric and spherical trigonometry (6) analysis and analytical geometry (7) stereometry, with indices to the whole work arranged (a) according to names and works, (b) according to subjects

As the editor explains, there is no pretension to literary style the account is summary, approximating to the brevity of a lexicon the object is, above all things to catch the eye and make the salient points stand out, as it were References are given in the notes to the original authorities for the statements made the fullness of these notes will be gathered from the fact that there are 1343 notes, of various lengths to 218 pages of text in the volume before us They are brought up to dates so late as 1929 and 1930 there are references to light years as units of distance, to Eddington's calculation of the diameter of the universe, regarded as finite under the relativity theory, to the latest researches into Babylonian and Egyptian mathematics by H Wieleitner, O Neugebauer, T Eric Peet, A B Chace, Kurt Vogel, and others to B Datta's papers on ancient Indian mathematics, and so on

There are and must be omissions We have not so far traced any reference to the Russian peasant' method of multiplication (by means of duplicating and halving only), which in effect comes to the same thing as the ancient Egyptian method In citing other works, the author does not always refer to the latest editions But, taken as a whole, the work is an invaluable, nay, indispensable, *Nachschlagebuch*, and we look forward with lively interest to the appearance of the remaining parts

Our Bookshelf.

Soviet Union Year Book, 1930 Compiled and edited by A A Santalov and Dr Louis Segal Pp viii + 670 (London George Allen and Unwin, Ltd, 1930) 7*s* 6*d* net

THE 'Soviet Union Year Book", which first appeared in 1925 as the Commercial Year-Book of the Soviet Union", is a bulky and informative volume, concerned chiefly, as its origin would suggest, with matters of commercial interest There are sections on the constitutional and political organisation of the Union of Socialist Soviet Republics and of its constituent republics, on the economic organisation and development of the Union, including a short notice of the Five Year Plan and separate sections dealing with agriculture, mineral resources, industry, transport, foreign trade finance and currency, labour and co operation There is also a legal section dealing only with private law

Of most interest to readers of NATURE are probably the sections dealing with education and with health Under the former heading we read that there were in 1928–29 in the U S S R, 109 Workers' Faculties with 60,200 students, and 134 universities with 155 300 students One would be grateful if subsequent issues of the 'Year Book' gave more information concerning these institutions there is nothing here concerning their organisation, their method of recruiting students, their geographical distribution or the subjects studied in them In the same section are included the numerous scientific institutes that have been opened in the U S S R and where research is being done in problems of applied science likely to assist the industrial development of the country A list of these institutes is given and, as a sample of their activities, a summary of the work carried out in the Chemical Institute Since the summary only occupies a page and a half, our curiosity is aroused rather than satisfied

The legal section includes an account of the Soviet Union laws on copyright, trade marks, industrial designs and patents, including the full text of the most important decrees and ordinances in the matter of patents

Other interesting features are maps, showing the new political and administrative divisions of the Union and the progress of electrification a list of the more important periodicals published in the Union, including several technical and scientific ones and a Who's Who" of scientific workers The value of the 'Year-Book" as a work of reference is increased by the presence of an index

The Universe around Us By Sir James Jeans Second edition Pp x + 363 + 24 plates (Cambridge At the University Press, 1930) 12*s* 6*d* net

COMMENT on this well known book is almost a work of supererogation, the remarkable popularity it has attained, which shows no sign of abating, makes praise superfluous and adverse criticism futile

The second edition shows little modification of the original book The size is increased by eleven pages, and a number of small alterations have been made, either in correction of errors of detail or as representing the superiority of second thoughts to first The increase of size is due mainly to a discussion of three subjects, described in the preface as the new planet Pluto, the rotation of the galaxy, and the apparent expansion of the universe It is an eloquent commentary on the present progress of astronomy that, in little more than a year, subjects of this magnitude and importance have either been born or experienced developments of fundamental character There is only one point in the book to which we might profitably direct attention The index includes, under the general heading "Quotations", a number of well-known names, but reference to the corresponding pages often shows no obvious quotation Presumably the reference to George Meredith in connexion with p 283 arises from the occurrence there, without inverted commas, of the isolated phrases "dusty answers" and "hot for certainties" A 'quotation' from Matthew Arnold, assigned to p 5, eludes us If phrases which have passed into current coin of the language are to be dubbed 'quotations', there will be no end to the acknowledgments necessary One wonders, for example, why 'new heavens and a new earth" on p 331 is not ascribed to St John, or even why the Psalmist is not given the credit for "down to the sea", on p 151 The point is a small one, but it is not beneath notice It is a penalty of reaching a high standard of excellence that small blemishes become unduly conspicuous, and this may serve as a justification for mentioning one of them here

Little America Aerial Exploration in the Antarctic and the Flight to the South Pole By Rear-Admiral Richard Evelyn Byrd Pp xvi + 422 + 58 plates (London G P Putnam's Sons, 1931) 21*s* net

AERIAL exploration has introduced a new kind of book on polar travel The two-volume account of the daily routine of sledge journey and camp has gone An aerial journey is so brief that there is little to say beyond comments on the behaviour of the machine Admiral Byrd made several remarkable flights during his year in the Antarctic and discovered considerable areas of new land, yet the bulk of the volume is descriptive of preparations for winter quarters and the journeys to and from New Zealand The flight to the Pole and back, which occupied nineteen hours, is described in a single chapter

The limitation of usefulness of aerial exploration is clearly brought out in this book, and Admiral Byrd wisely supplemented it with ground work where possible Thus Prof Goold's examination of the Queen Maud range was one of the most important aspects of the work Unfortunately, the new land east of King Edward Land was not examined The expedition had its base at the Bay of Whales on the Ross Barrier, out of sight of land, so that the majority of the large complement of forty-two men never got a glimpse of Antarctic land Another innovation in Antarctic exploration was the daily contact by wireless with the outer world and the inclusion of a press correspondent in the staff The book contains little record of scientific results, which were considerable, but has much information about flying conditions

Oxydations et reductions Par René Wurmser (Les problèmes biologiques, Vol 15) Pp xix + 381 (Paris Les Presses universitaires de France, 1930) 95 francs

PROF WURMSER has produced a really excellent book on oxidation and reduction, of value not only to those interested in the physical and chemical aspects of biology but also to the general scientific reader as well He commences with the principles of oxidative and reductive processes as illustrated by changes in valency, by electron transfer, and diminution in free energy The various mechanisms of the operation of both photochemical and thermochemical processes of oxidation and reduction are then developed, and two chapters are devoted to a critical discussion of the hypotheses involving 'activation' of hydrogen and 'activation' of oxygen respectively According to the author, these theories must not be regarded as rivals, but that processes of oxidation and reduction operate by one or the other mechanism Attention is then directed to the determination of oxidation, reduction equilibria, including not only those readily reversible but also those which are only partially reversible in systems for which the evidence for reversibility is at present somewhat scanty The volume concludes with a discussion of experimental technique and a summary of the results obtained in the study of intracellular oxidation-reduction potentials The book is well written, in that it is a veritable mine of information yet at the same time eminently clear and readable The printing and binding are both superior to the average text-book of French origin

E K R

Foundations of Biology By Prof Lorande Loss Woodruff Fourth edition Pp xvi + 501 (New York The Macmillan Co, 1930) 3 50 dollars

THIS is regarded in many universities as a standard text book for the student's own reading It gives the zoologist the necessary essentials of botany, and shows an understanding of the part played by unicellular organisms The diagrams are simple and admirably selected, many being original Technical terms are reduced to a minimum, and the student is helped also by an admirable glossary The new edition is a great improvement, and the more adequate discussion of many themes will make them simpler to the student The enlargement of the section devoted to human welfare is useful We ourselves are rather tired of the evolution of the horse, in the next edition the author should explain what a horse is and how it is adapted to its environment, for his students will not know

Letters to the Editor.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE *No notice is taken of anonymous communications*]

Observations on the Penetrating Radiation in the Antarctic.

OBSERVATIONS upon the variation of intensity of the penetrating or cosmic radiation with latitude were carried out by the B A N Z Antarctic Research Expedition during the recent summer cruise of the *Discovery*, November 1930 to March 1931

All observations during the voyage were made by Mr A L Kennedy, physicist to the expedition The apparatus employed was a Geiger Muller electron tube counter, with single-stage amplifier, relay, and automatically recording chromograph The tube counter was contained in a Pyrex glass tube, into which tungsten leads were sealed and filled with argon gas at a pressure of approximately three centimetres mercury The tube was mounted between lead blocks in such a way that, except for the holes through which the ends of the tube projected, four inches of lead surrounded the tube on every side

The pressure of the argon was adjusted to give a counting-voltage between 450 and 500 volts, and a series resistance of the order of 1500 megohms consisting of a suitably proportioned mixture of xylol and alcohol in a hermetically sealed Pyrex capillary gave potential 'kicks' for each discharge through the tube The whole apparatus was mounted in a small room on the deck of the *Discovery*, adjoining the wireless room Of six tubes made in the physics laboratory of the University of Adelaide, only one survived the voyage Fortunately, counts were obtained on this tube over a region ranging from Hobart to Adelie Land, that is, over a range of geographical latitude from 43° S to 68° S

Counts were made on thirty four days during the voyage, and the total number of 'kicks' recorded was 28,350 in a total time of 4502 minutes, giving an average rate of 6 3 'kicks' per minute Except on two occasions, when values of 7 5 and 7 2 were obtained, the variations from this mean are of the order due to probability variations, and both these high values occurred early in the voyage with values of a 'counting voltage' higher than was usual The counts for the two stations nearest to the magnetic pole, with the ship stationary off Adelie Land, show values of 5 9 per minute and 6 3 per minute There is thus no definite indication of variation with magnetic latitude

Unfortunately, an overcast state of the sky was so general that no attempt at a correlation of electron counts with auroral intensity is possible On the one occasion on which the log book records the occurrence of a brilliant aurora, the count was, however, unusually low (5 6 per minute)

The mean value (6 3 per minute) of all counts on the voyage is identical within the limits of experimental error with the value (6 1) obtained for a count of four hours in the physics laboratory of the University of Adelaide

The result of the observations thus tends to confirm those of Bőthe and Kohlhörster in the North Atlantic (kindly communicated in a letter from Dr Bőthe), of Corlin at Abisko, and of Millikan at Churchill in Canada, in showing that the intensity of the penetrating radiation does not vary to any considerable extent with magnetic latitude even within 250 miles of a magnetic pole

The accuracy of the observations probably does not exceed ten per cent at best, but it should be noted that they were taken in circumstances of exceptional difficulty, illustrated by the following extracts from the log-book "Roll 40°." "Stopped Radio transmission started" "Very big seas, stormy, rolling heavily . bottle P_2O_5 rolled on to instrument, putting it temporarily out of action."

Difficulties with regard to temperature, which affects the voltage of the H T battery, and humidity, which affects the insulation, were also formidable The former could not be controlled, but the latter was successfully countered by using sulphur as an insulating material and by surrounding the end of the Pyrex tube with a sleeve containing phosphoric anhydride

The preliminary work of adjusting gas pressure in the counting tube, determining the counting-voltage, etc , was carried out by Mr Iliffe, of the staff of the physics laboratory

The Nuclear Moments of Cæsium, Rubidium, and Indium

IN my work [1] on the hyperfine structure of the lines of the principal series of cæsium, I suggested that $\frac{7}{2}$ was the value of i, the quantum number of the rotation of the nucleus , but I pointed out that it might well be higher, it being impossible to determine it with certainty owing to the hyperfine structure of the P levels being too fine to resolve In the meantime Schuler [2] has shown that the value of nuclear quantum number can be determined quite simply from the intensity ratio of the components of the hyperfine structure doublets In cæsium the two components are of very nearly equal intensity , so that the value of i must be high it may well be 9/2, or perhaps higher , in order to find the exact value, experiments are being made to determine very accurately the intensity ratio of the components

I have also examined the structure of the lines $1S_{\frac{1}{2}} - 3\,{}^2P_{\frac{1}{2}}$ and $1S_{\frac{1}{2}} - 3\,{}^2P_{\frac{3}{2}}$ of rubidium These possess a doublet structure with a separation of about 0 1 cm^{-1} , but the intensity ratio of the two components is about 2 1 , this corresponds to a value of 1/2 or 3/2 for i , the values of the intensity ratio being respectively 3 1 and 5 3 for these two values The structure is probably affected to some extent by the isotope of higher atomic weight , but as this is only present to the extent of about 25 per cent, the value of i for the principal isotope must still remain within the limits given

The value of i for indium [3] is given as one , this is almost certainly too low It was calculated by Goudsmid's cosine law [4] from the separations of two very close levels The ratio of these separations was found to be 0 072 ± 006 0 045 ± 006 , that is some value between 2 1 and 1 3 1 The corresponding value of i is between 1 and 7/2, if these limits of experimental accuracy are taken into consideration But here again additional evidence is given by consideration of the intensity ratios of the fine structure components , this corresponds to a high value of i It is therefore to be assumed that the upper limit of the range of values found by the cosine law, namely, 7/2, is the more probable

The experimental results are of course in no way affected by this revised theoretical interpretation.

Goudsmid has suggested that my experimental results for the hyperfine structure of indium are

uncertain, as they do not agree with some results obtained by McLennan.[5] A careful study of both works on the subject shows that the difference between McLennan's results and mine is just what is to be expected, if the lower resolving power with which McLennan worked is taken into consideration. The line 4101, I found to possess four components with separations 0·000, 0 281, 0 380, and 0 658 cm $^{-1}$ now the component at 0 380 cm $^{-1}$ is weak and very close to the component at 0 281 cm $^{-1}$; consequently, except with very fine lines and high resolving power, it could not be observed and the line would appear to possess only three components, as McLennan observed Similarly, in the case of the line 4511, I observe four components, while McLennan only observed two, now the separations of the four components are 0 000, 0 045, 0 204, and 0 276 cm $^{-1}$ here the components at 0 000 and 0 276 cm $^{-1}$ are weak and very close to the strong components at 0 045 and 0 204 cm $^{-1}$, so that except with the highest resolution they escape detection and the line appears to be a doublet, which is just what McLennan observed

In order to see the full structure of the lines, it is necessary to work with a resolving power of at least 500,000, this I achieved by using a reflecting echelon grating with a resolving power of about 800,000 and a light source which operated at the very low temperature of about 80° C With any less adequate means it is quite impossible to observe the smaller separations

Effect of Fungi upon the Strength of Timber

THE fact that fungal decay considerably lowers the strength of timber has long been familiar to all who employ this material for structural purposes, but practically no information has been available as to the actual amount of damage caused in any specific wood at various stages of decay Recently it has been shown that almost imperceptible decay may render Sitka spruce timber unsuitable for use where high mechanical strength is required An investigation carried out at Princes Risborough by the Forest Products Research Laboratory of the Department of Scientific and Industrial Research has now taken the matter a step further The rate of loss of mechanical strength in pieces of timber exposed to the attack of a fungus growing in pure culture, with the chemical and other changes taking place in the wood, have been accurately followed

The timber used in these experiments was Sitka spruce, one which is unusually homogeneous and therefore suitable for the mechanical testing and analysis of small samples, it is also a wood frequently used in structures such as aeroplanes where any deterioration of its strength may be a serious matter Previous work at the Laboratory has shown that this timber in certain circumstances is very susceptible to decay, and the fungus *Trametes serialis*, chiefly responsible for the development of brashness in it, has been studied.[1]

A large number of small, carefully selected test pieces were inoculated with cultures of *Trametes serialis* actively growing upon agar medium in culture flasks in which a high humidity was maintained

A number of test pieces were removed from the cultures after periods of exposure to the fungus varying from one to ten weeks, and tested for strength upon apparatus specially designed for the purpose; while at the same time matched control pieces, which had been kept sterile, were tested The progressive loss in weight and chemical change by the fungus were also determined, and these results were correlated with the strength figures Sections were cut from certain of the test pieces and examined microscopically.

Two sets of experiments were carried out and the results will shortly be published as a Forest Products Research Bulletin In each series there was an extremely rapid fall in the strength values, after only two weeks in the second experiment the average value for the strength of the pieces had fallen to about 80 per cent of that of the normal sound pieces, and afterwards the mechanical strength continued to fall rapidly until after ten weeks less than 20 per cent remained

This loss in strength could be closely correlated with the chemical changes brought about by the fungus The curve for the change in alkali solubility 'shadowed' quite closely the curve for the strength values It is of interest, however, to note that loss in weight of the specimens did not become significant until several weeks after the strength of the timber had begun to fall The increase in alkali solubility of the wood substance preceded the loss in weight caused by the respiration of the fungus

Examination of the sections of the test pieces showed that the hyphæ of the fungus rapidly permeated the blocks and penetrated the cell walls, but the amount of mechanical damage caused by the formation of small bore holes could not be considered as the chief factor responsible for lowering the strength of the wood, which should rather be looked for in the chemical changes in the material of the cell walls brought about by the fungus

An Unusual Solar Halo Complex

AN unusual halo complex was observed at Saskatoon, Canada, on April 16 between 8 20 A M and 9 15 A M, 105th meridian time Its appearance when the altitude of the sun was about 35° is shown in the accompanying diagram (Fig 1) The significance of the various letters is as follows *HH*, horizon, *Z*, zenith, *S*, sun, *aa*, halo of 22°, *ee'*, parhelia of the halo of 22°, *cc*, *c'*, upper and lower tangent arcs of the halo of 22°, *bbb*, portions of the halo of 46°, *d*, arc tangent to the halo of 46°, *mm*, parhelic circle, *pp'*, parhelia of 90°, *tt'*, parhelia of 120°, *h*, anthelion, *ss'*, narrow angle oblique arcs of the anthelion, *rr'*, apparently portions of wide angle oblique arcs of the anthelion, *gg'*, apparently secondary parhelia of the parhelia of 22°, *f*, arc vertically above, and concave towards the sun Coloured halos and arcs are shown by a solid and a dotted line, the latter indicating the blue side of the halo

Features which are worth noting in this halo complex are (1) the colour of the oblique arcs *r*, *r'*, and (2) the arcs *f* and *d* When the arcs *r*, *r'* were observed first they were so faint that it was impossible to be certain of their colour, but shortly before the disappearance of the halo they brightened to such an extent that the red colour on the side next the horizon was very noticeable The ends of the arc *f* appeared to merge into the upper horizontal arc *cc*, and the region enclosed by the two was much brighter than

the surrounding sky This arc appeared to have its centre at the sun, and was separated from the halo of 22° by an angular distance of about 3° Its position with respect to the halo of 22° did not appear to change with time, although the intensity of the light from it decreased more quickly then than that from other parts of the halo The arc *d* was not noticed

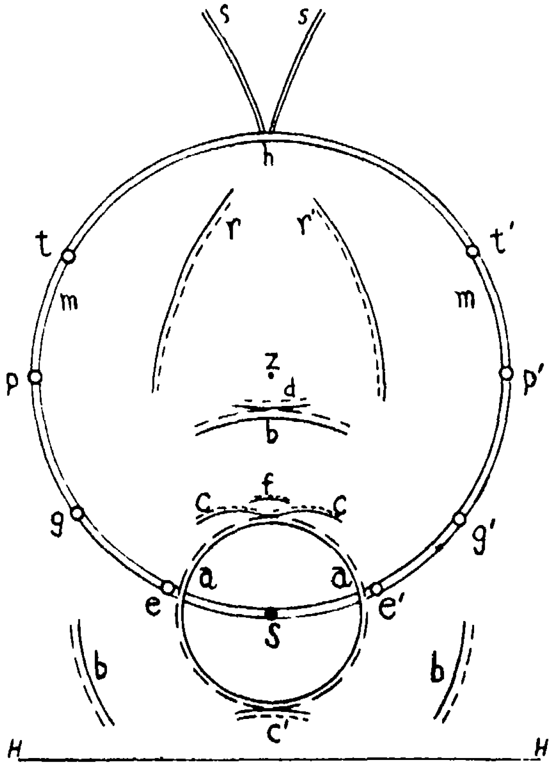

FIG 1

until several minutes before the disappearance of the halo, when it appeared as a short, brightly coloured arc, curved towards the zenith

Although halos are an infrequent occurrence in western Canada, halos of varying degrees of complexity were seen almost daily during the second and third weeks of April During this period of time there were two large dust storms, and it is suggested that small dust particles, carried to the level of the cirrus clouds, may have served as nuclei for the formation of ice crystals

Arabic Source of Zadith's "Tabula Chemica"

THE basal texts of the alchemical knowledge of the Middle Ages in Europe are the "Turba Philosophorum" and the "Tabula Chemica" of Senior Zadith, son of Hamuel, but although both of them are obviously derived from Arabic sources, the latter have not hitherto been traced Some twenty-five years ago an Arabic manuscript containing three of the works—two in verse and the other in prose—of the tenth century alchemist Muhammad bin Umail came into our possession from Lucknow, and the work in prose, entitled "Al-Mā'al Waraqī wa-l Arḍ an-Najmīyah" ("Silvery Water and Starry Earth"), was cursorily examined, as—being largely a compendium of quotations from older alchemical writers—it seemed likely to throw some light on a similar work (the "Shawāhid") of the well-known authority on alchemy, Muhammad bin Zakarīya ar-Rāzī, who died in A D 925 As, however, no connexion could at the time be established between the two works, and the Indian text was somewhat defective, the manuscript was put on one side until its collation with other manuscripts of the same work could be made

This was not found possible until 1926, when the grant of a research scholarship by the Government of Bengal to Maulvi Turāb 'Alī enabled the work of collating the Indian text with photostat copies of two other manuscripts—one at Paris and the other at Leningrad—to be taken up It was then noticed by one of us (H E S, while on leave in England in 1927) that the contents of the "Mā'al-Waraqī" were very similar to the treatise of Senior Zadith, and comparison of the Latin text in vol vi of Zetzner's "Theatrum Chemicum" (Strasbourg, 1659) showed not only the identity of the two texts, Latin and the first half of the Arabic, but also that both were a commentary on one of the poems contained in the Lucknow manuscript, and, partially, also in the treatise of Senior The name of this poem is "Risālatu sh Shams ila l-Hilāli", which appears in the Latin under the literal translation "Epistola Solis ad Lunam Crescentem" A portion of the Latin translation of the "Mā'al Waraqī" was also found to be included in the compendium of alchemical treatises known as "Artis Auriferæ quam chemiam vocant" (1593 ed, pp 246-256) under the incorrect title "Rosinus ad Euthiciam" This last named volume includes two versions of the "Turba Philosophorum", and it was next noticed that the latter work includes at least three passages that are to be found in the "Mā'al Waraqī" Finally it was discovered that not only had the author of the "Mā'al Waraqī" drawn some of his materials from both Ar Rāzī's "Shawāhid" and another treatise by Ar-Rāzī's immediate predecessor, Mahrārīs, but also that the fourteenth century treatise of the Arabic alchemist al 'Irāqī, "Kitāb al 'Ilm al Muktasab fī Zira'at adh-Dhahab" (edited and translated by Dr E J Holmyard in 1923), was largely based on the "Mā'al Waraqī"

A paper on the subject (which will include both Maulvi Turāb 'Alī's recension of the Arabic text as well as an edition of Senior Zadith's "Tabula Chemica") is now being published in the *Memoirs of the Asiatic Society of Bengal*, and an account of the recent discoveries, which throw much light on the history of chemistry, will be given at the Second International Congress of the History of Science and Technology that will be held at South Kensington at the end of June

Two Modifications of Liquid Carbon Disulphide

THE data of H Isnardi [1] show that the dielectric constant of carbon disulphide undergoes at the temperature of − 90° C. a sudden change This phenomenon appears at a considerably higher temperature than the freezing point of carbon disulphide (− 112°), it is thus similar to ethyl ether On the basis of our work on ethyl ether we may therefore suppose that the carbon disulphide undergoes at − 90° C a transformation from one liquid modification into another one

To confirm this assumption, we have made a study

of the heating curve of carefully chemically purified carbon disulphide The apparatus used in this study was the same as that used previously for ethyl ether and nitrobenzene [2] Carbon disulphide was cooled to a temperature − 93°, we then observed the change with time of the gradually increasing temperature of the substance, which was isolated from all external thermic influences The observations of temperature were made in intervals of 10 sec The observations, repeated five times, have shown that at − 90 03° there appears a distinct break on the heating curve (see the part *AB* of the curve on the accompanying graph, Fig 1) Both parts of the curve, above and below *AB*, are to a high degree of approximation straight lines, making appreciably equal angles with the axis of time This shows that the specific heat of carbon disulphide does not undergo an appreciable change

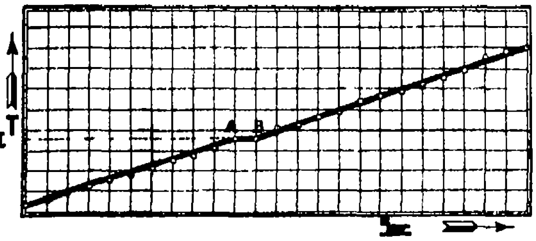

FIG 1

at the transformation point Measurement of the value of the refractive index as a function of temperature shows also a break at this point

It should be mentioned that the existence of two different liquid modifications of carbon disulphide could be distinctly observed during the cooling of the substance, because the two modifications do not mix together and so a sharp dividing line can be seen This dividing line between the two liquid modifications can also be sharply seen during the slow heating of carbon disulphide This phenomenon depends, of course, on the sharp change of the refractive index

The heat of transformation, estimated roughly from the heating curve, is for carbon disulphide about 0 04 cal /gr, for ethyl ether 0 07 cal /gr, for nitrobenzene 0 14 cal /gr All these values are of the order of the heat of transformation of helium I into helium II [3]

The phenomenon reported in the present communication is the third case observed by us of the existence of two different liquid modifications of an organic substance

Bridges' Genic Balance Theory of Sex Determination

IN Bridges' table of sex indices,[1] in connexion with balanced intersexuality in *Drosophila*, the fact that the female intersex is a triplo IV and the male intersex a diplo IV is not expressed The chromosomal difference between the two is not allowed for in the calculation of the series of sex indices Since the addition of a IV chromosome to the male intersex chromosome relation converts it into a female intersex, the "IV chromosome must have a net female tendency similar to that of the *X* and different from that of the other autosomes" The following modification is, therefore, suggested

X and IV represent the totality of female determining genes

II and III represent the totality of male determining genes

The addition of one IV chromosome to the chromosomal complex of the *male intersex* converts it into a *female intersex* On the other hand, the addition of an *X* chromosome to the male complex converts the *male* into a *female* The efficiency of the female determining genes on the IV chromosome must consequently be very much less than those on the *X* chromosome

Assigning arbitrary values to the efficiencies of the two interacting components, male on the autosomes II and III, and female on chromosomes *X* and IV, the subjoined series of sex indices is obtained

Let the efficiency of the female determining genes on the *X* chromosome be represented by $100 = f$, that on the IV chromosome by $10 = f'$, and the efficiency of the male determining genes on II and III chromosomes be represented by $100 = M$

Chromosome Relation	Gene determining Relation	Sex Type	Sex Index
3X 2A	$3f+2f'$ $2M$	super female	1 60
4X 4A	$4f+4f'$ $4M$	4N female	1 10
3X 3A	$3f+3f$ $3M$	3N female	1 10
2X 2A	$2f+2f'$ $2M$	2N female	1 10
1X 1A	$1f+1f'$ $1M$	1N female	1 10
2X 3A	$2f+3f'$ $3M$	female intersex	0 77
2X 3A (−IV)	$2f+2f'$ $3M$	male intersex	0 73
1X 2A	$f+2f$ $2M$	male	0 60
1X 3A	$f+3f'$ $3M$	super male	0 43

This table represents more accurately the genotypic differences of the various sex types, more especially the difference between the male and female intersexes, and can be applied to Bridges' suggestion that "by variation in the number of IV chromosomes, it is possible to have a fringe of minor sex types about each of the major types of sex difference"

Forestry Research in Great Britain

THE correspondence in NATURE and the leading article on "Forestry Research in Great Britain" in the issue for May 16 lay stress on certain points which need to be emphasised It appears, however, that an even wider view of the problems must be taken if we are to make the most of our opportunities and of our obligations Every schoolboy knows about the struggle for existence, the survival of the fittest, and similar phrases, but it is rare to meet a forester who has been trained to pay attention to the analysis of the factors as they occur either in natural woodlands or in plantations This is not surprising, for intensive research in fundamental problems has been almost completely neglected in Great Britain

Some attention has been paid to a few obvious diseases, but the results are almost negligible compared with what is known about fungal attack when timber has been worked, though these are often part of the same problems and should be treated as such

The fungus root (mycorrhiza) of trees is equally a subject which should be investigated seriously Little or nothing has been done in Britain, and no one has been wholly engaged in its study It does not seem

to have been realised generally that casual identifications of woodland fungi presumed to be operative are worthless, and moreover, that these fungi when they are not concerned with mycorrhizal roots have, nevertheless, an influence on the fertility of the soil, for the mycelium ramifies amongst leaves and obtains its nutriment from them

The work that other fungi accomplish in the soil is also a matter for research, it is certain that they are as important as bacteria, but I know of no work on them here or elsewhere

The conditions overseas in natural forests are disturbing, when one considers both exploitation and replanting On the last visit of the British Association to Africa I was told that it was of no use my going to a certain forest if I wanted to collect fungi, I was repaid for my scepticism by the two best collecting days in twenty years' experience

I have directed attention to the major activities of a single group of organisms, but even less is known about the more indirect ones of other cryptogams We need still to keep cats and clover in mind

With so many research problems crying out for attention, and the Breckland area within easy distance, it would seem that the Cambridge Forestry School might be saved from the fate which threatens it

We have followed the German school more or less blindly and we should be unwise now merely to follow the Swedish school Darwin first clearly pointed out the interplay between different organisms, and this principle applied with modern ecological methods of research would lead to the practical results by which the forester must, in the end, judge them

The Low Altitude Aurora of Nov 16, 1929

In Nature of May 2, p. 663, Dr G C Simpson has compared the observation of an aurora in Abisko on Nov 16, 1929, mentioned by me in Nature of April 11, 1931, with an observation of an aurora made by him twenty seven years ago After a description of the last mentioned aurora, he arrives at the following conclusion "It is clear that these two experiences were practically identical, and there can be little doubt that what Mr Corlin considered to be the thicker parts in the cloud covering were really breaks in the cloud through which the dark sky could be seen"

There are, however, two important differences in the observations mentioned, which show that this conclusion cannot be valid, namely—(1) during the observation at Abisko the *cloudy structure* of both the thinner and the thicker strata could be easily seen, so that there is no doubt at all that they were clouds and not "the dark sky" in addition, some few real breaks in the clouds elsewhere showed that the uncovered sky was light blue owing to the moonshine, (2) the auroral ray observed at Abisko was apparently equally intense in front of both the thinner and the thicker strata with rather sharp limits, whereas the aurora observed by Dr Simpson showed "bright and dark patches owing to the clouds" Therefore the auroral ray at Abisko on Nov 16, 1929, was either in front of the clouds or was far above the clouds, but had a greater intensity than the full moon

Auroræ brighter than the full moon may possibly occur on rare occasions An extremely bright aurora of possibly so high intensity was, for example, observed on Jan 5, 1930, 3h 30m G M T, by the caretaker of the tourist station at Abisko, who awoke from his sleep and first thought that the tourist station was burning, but found that an aurora of extraordinary intensity was flashing all over the sky. Therefore, I have not been 'convinced' that the auroral ray on Nov. 16, 1929, was really below the clouds, but after reading later Mr Cummings's observation of a low altitude aurora in Norwood, Canada, *on the same day* (Nature, Jan 17, 1931), I now find it more probable that a low altitude aurora (being thus a planetary phenomenon) really occurred on that day both at Abisko and at Norwood than that we should have by chance the same curious 'illusion' on the same day at places so far apart

The Inheritance by a Leafhopper of the Ability to Transmit a Plant Virus

Leafhoppers of the species *Cicadulina* (*Balclutha*) *mbila* Naude, after feeding upon a maize plant affected with the virus disease known as 'streak', will usually transfer this disease to all healthy maize plants upon which they may subsequently feed In the course of studies of the virus transmission by this species of insect, however, I have frequently encountered individuals which failed to transfer the virus under conditions normally favourable to this process Repeated tests of these individuals, after further periods of feeding upon diseased plants, led me to believe that they were incapable under the experimental conditions, of acting as vectors of this virus

I have recently studied the inheritance by this insect of the ability to transmit the streak virus by breeding successive generations from parents selected for this character In this way I have obtained races which breed true for the character selected Thus certain races, which may conveniently be called the 'active' races, consist of hoppers, every individual of which will invariably transfer the streak virus under suitable conditions On the other hand, 'inactive' races have been raised in which every individual is incapable of transferring the virus I have failed to find any morphological difference between the hoppers of these several races

In the course of this pure line breeding it became clear that the character of 'activity' behaved in inheritance as dominant to the character of 'inactivity' Later study of crosses between the two pure-breeding races confirmed this conclusion and, furthermore, showed that the character was linked with sex Thus the cross, active ♂ × inactive ♀, gave an F_1 progeny of inactive ♂♂ and active ♀♀ In the F_2 generation, active and inactive hoppers appeared in approximately equal numbers in each sex The reciprocal cross, inactive ♂ × active ♀, gave an entirely active F_1 offspring, and segregation in the F_2 generation into active and inactive ♂♂ in approximately equal numbers, and only active ♀♀

These results conform with the well-known *Drosophila* type of sex-linked inheritance

Fourth Centenary of the Collège de France.

AMONG the great educational institutions of Paris the Collège de France, founded by Francis I in 1530 as the Collège Royal, is one of the oldest and most famous, and this week (June 18–20) is celebrating the four hundredth anniversary of its foundation The celebrations commenced with receptions in the Collège itself and at the Hôtel de Ville, on June 19 there was a gathering in the great amphitheatre of the Sorbonne, presided over by the President of the Republic, and on June 20 a visit is to be paid to the château of Francis I at Fontainebleau, and a gala performance will take place at the Théâtre Français During the forenoons of June 18 and 19 there are to be conferences in the Collège de France, when discourses on the development of the various sciences are being delivered by MM Sylvain Lévi, H Vincent, Paul Langevin, and Edmond Faral, while in the Bibliothèque Nationale an exhibition has been arranged recalling the work of the men who have added lustre to the name of the Collège

Francis I has been described as a prince of excellent abilities, kindly disposition, rash and generous, but licentious and without principles Like many others, his reign, which began in 1515 and ended in 1547, was marked by long wars and much persecution Yet it was also marked by an increasing interest in literature and art, and Francis is remembered as the protector of Rabelais, the patron of Leonardo da Vinci, and the friend of Erasmus His age was that of the Reformation, the age of Luther and Calvin, which was likewise the age of Michelangelo, of Durer, of Copernicus, of Vesalius, of Paracelsus, and of Georg Agricola The sack of Constantinople in 1453 had made the treasures of the ancient world available for all mankind, learning in all its branches had received new impetus, and the founding by Francis I of the Collège de France was but one outcome of a momentous movement Inaugurated under the most promising auspices, free from clerical restraint, and devoted to all branches of knowledge, the Collège, like many similar institutions, has passed through periods of stagnation, and at one time its chairs were bestowed by ministers on their family doctors or tutors to serve as pensions, but during the later part of the eighteenth century it was reconstituted, and it has ever since played a conspicuous part in the intellectual life of Paris When founded in 1530 the lectures were given in different colleges, but the present building near the Sorbonne was commenced in 1610 and was completed about 1778 Bearing over its doorway the inscription *Docet Omnia*, the Collège to day possesses more than forty chairs, and all its lectures are public and free

Not the least interesting feature of the Collège is its collection of busts and memorials which help to recall its history Though some of its professors have left behind them little but their names, there have been many who by their writings, their discourses, their researches or discoveries, have added vastly to the spread and increase of knowledge The first professor of mathematics, chosen by Francis himself, was Oronce Fine (1494–1555), the author of thirty one works and the constructor of models which were still in existence at the time of the Revolution Another mathematician was a far more famous man, Pierre de la Ramee (1515–1572), better known as Ramus, who fell a victim to the massacre of St Bartholomew His works on arithmetic, geometry, and algebra were the standard text-books, and he was as distinguished as a philosopher as he was as a mathematician Among his pupils was the almost forgotten Jean Pena, who translated Euclid's "Catoptrica", but who died at the age of thirty Roberval (1602–1675), the opponent of some of the views of Descartes and the supporter of those of Copernicus, became professor of mathematics in the college in 1632, and in 1645 Gassendi (1592–1655) was made one of his colleagues Picard (1620–1683), the astronomer, was first the assistant and then the successor of Gassendi, while a successor of Roberval's was La Hire (1640 1718) To Picard and La Hire belongs the credit of being the first to use the newly built Paris observatory for regular observations, and together they were employed by Colbert on the construction of a map of France Duhamel (1624 1706), the first secretary to the Academy of Sciences, Sauveur (1653–1716), the partly deaf founder of the science of acoustics, and the mathematician Varignon (1654 1732), whose "Projet d'une nouvelle mécanique" appeared the same year as Newton's Principia", were all associated with the Collège at the end of the seventeenth or the beginning of the eighteenth century

It was soon after this that the fortunes of the Collège sank to their lowest ebb, when no one spoke of it, and its posts were bestowed as pensions Under Louis XV the tide turned, orders were issued for its reorganisation, and through Delisle, Lalande, and others its halls again became a centre of attraction Delisle (1688–1768), the friend of Newton and Halley, had spent twenty years in Russia before he became a professor at the Collège de France, and Lalande (1732–1807), his successor, had likewise spent a short time at Berlin As anxious to call public attention to himself as to astronomy, Lalande became the most popular exponent of science of his day, and he stands in the first rank as a professor and a writer Succeeding Delisle in 1762, he held a chair at the Collège de France for nearly forty six years One of Lalande's best known contemporaries was Darcet (1725–1801), a chemist known for his study of the manufacture of pottery With Monge he was one of the earliest explorers of the Pyrenees, and his lecture in 1775 on his experiences was the first ever delivered at the Collège of Science in the French instead of the Latin language

Surviving the Revolution almost unchanged, the Collège de France, under the Napoleonic era, like the Institut, the École Polytechnique, the École Normale, and the Jardin des Plantes, became one of the scenes of the activities of the brilliant group

of men of science which made that era so memorable in the history of science Never before or since, perhaps, has there been gathered together in one city so many of the world's greatest contributors to the advancement of knowledge as there were in Paris at the beginning of the nineteenth century, and it was but natural that the Collège de France, with its unfettered regime and its public lectureships, should become one of the homes of those who spoke with authority One eminent man who held office during the Revolution was Daubenton (1716–1800), the collaborator of Buffon When he died, his chair passed to none other than Cuvier (1769–1832), the founder of palæontology and comparative anatomy, whose last lecture was given in the Collège only a few days before he died Contemporary with Daubenton and Cuvier were the chemist Vauquelin (1763–1829), the discoverer of chromium, Thenard (1777–1857), in whose favour Vauquelin resigned in 1804, and Biot (1774–1862), who in 1800, at the age of twenty-six, was appointed professor of natural philosophy

No less distinguished were the successors of these famous men In the realm of physiology there are few names better known than those of Magendie and Bernard Magendie (1783–1855), who described himself as a "rag picker of facts", and on his death bed remarked to a friend, "You see me here completing my experiments", became a professor in 1831, the year he visited Sunderland to study cholera To him in 1847 as an assistant came Claude Bernard (1813–1878) who succeeded to Magendie's chair in 1855 Bernard's life as a Master of Medicine was written by Sir Michael Foster To the chair of experimental physics at the college in 1824 was appointed Ampère (1775–1836), the centenary of whose publication of the fundamental laws of electro-magnetism was celebrated at the Sorbonne ten years ago, and at his death, Savart (1791–1841), who for eight years had been curator of the physical cabinet, succeeded him Savart in turn was followed by Regnault (1810–1878), who, like Faraday, after having obtained a reputation as a chemist, turned physicist Regnault in 1854 was made director of the Porcelain Factory at Sèvres, and it was there, and not at the Collège de France, that his apparatus for the investigation of the expansion of gases was destroyed during the German occupation of 1870 Two years after this Regnault resigned his position at the Collège de France, and his chair passed to his deputy Mascart (1837–1908), afterwards destined to be director of the Central Bureau of Meteorology and president of the Paris Academy of Sciences What Biot and Ampère and their successors did for physics was paralleled by the work of the eminent chemists who followed in the chairs of Darcet and Vauquelin Pelouze (1807–1867), the successor of Dumas at the École Polytechnique, lectured for many years at the Collège de France, and in 1850 was succeeded by Balard (1802–1876), who had achieved fame at the age of twenty four by his discovery of the element bromine Balard was closely associated with many notable men of science He owed much to Gay Lussac, it was in Balard's laboratory, at the École Normale, Pasteur in 1848 made his remarkable discovery with tartaric acid, to him in 1837 as an assistant came Berthelot, while his assistant in later years, Schutzenberger (1829–1897), in 1876 became his successor Almost the whole career of Berthelot was bound up with the Collège de France, where in 1865 a chair of organic chemistry was created for him When he died forty two years later it was said that France had lost her most eminent man of science No one ever associated with the historic Collège was more convinced of the moral and practical value of scientific inquiry, and he once wrote "La Science domine tout"

Induced Malaria.

It is well known that, for some time past, malaria has been purposely induced as a remedial measure in persons suffering from general paralysis of the insane The therapeutic value of this proceeding has been placed beyond doubt Up to 1928, of 2499 patients in institutions in England and Wales so treated, 1188, or 47 5 per cent, were benefited sufficiently to be recorded as 'recovered', 'much improved', or 'improved' Of 656 cases in 1929, 47 7 per cent came under the same heading The 'discharged recovered' numbered nearly 12 per cent, and the 'discharged relieved' six or seven per cent Thus nearly one fifth of the cases treated by artificial infection with malaria benefit sufficiently to be discharged from hospital

From a medical and a moral point of view, therefore, there is abundant justification for subjecting sufferers from one malady, grave and intractable, to the risks attendant upon infection with another which is controllable by drugs At the same time, it has become apparent that the procedure affords a unique opportunity for the clinical study of malaria itself, a disease incomparably more important than general paralysis of the insane as a world problem, and one which is still beset by questions scarcely answerable in the uncontrolled conditions of the field

Arrangements were therefore made at the suggestion of Col S P James, adviser on tropical diseases to the Ministry of Health, whereby the Ministry, in consultation with the Board of Control, the London County Council, and Col J R Lord of Horton Mental Hospital, Epsom, organised what is virtually a first essay in clinical investigation under strictly experimental conditions Colonel James communicated a report on the first results to the Malaria Commission of the League of Nations in 1926, and communicates a record of the material which has since accumulated to the *Transactions* of the Royal Society of Tropical Medicine and Hygiene (**24**, 5, 477-538, March 1931)

It is very difficult to find malaria patients who can infect *Anopheles maculipennis* Of 305 mosquitoes dissected when sporozoites should have

been present in the salivary glands, ten only were found with zygotes in the stomach and none with sporozoites in the glands They were among eight batches fed, some of them as many as five times, upon the blood of patients with a high gametocyte count Dr P A Buxton suggests that a gelatinous sleeve, such as Schaudinn has described (perhaps present only at a certain phase in the process of digestion), arises from the chitogenous cells of the fore-gut and intervenes between the blood and the epithelium of the mid gut of the insect, thus accounting anatomically for the heavy infection of some *maculipennis* and not of others While the problem of insect infection needs further study, it has been ascertained that the condition of the gametocytes of *P vivax* in the blood of patients who are 'good infectors of *Anopheles*' is such that the male forms of the parasite in thin blood films kept moist at 25° C 'exflagellate' within fifteen minutes With *P falciparum* and *P malariae*, even this indication of infectability for *Anopheles maculipennis* is uncertain There are good and bad receptors of infection as well as good and bad infectors But there is no positive evidence that a particular species of *Anopheles* is a better 'malaria carrier' than another

If susceptible patients are bitten by mosquitoes which have sporozoites in their salivary glands, infection does not always result This may be accounted for by non injection of sporozoites Excluding such cases and also cases in which there was doubt whether or not the patient had suffered from malaria previously, 18 per cent of the number of patients who certainly received sporozoites failed to develop malaria within the usual incubation period These are held not to be attributable to the presence of 'immune bodies' in the patients' blood Some are examples of 'latent infection', others may be due to an anaemic or otherwise abnormal physiological condition of the blood

Failure may also result from the fact of a previous attack, and some of Col James's most suggestive results concern the course of malaria in cases treated by quinine In cases of so-called 'spontaneous recovery' from benign tertian malaria the infection 'smoulders', and the blood picture and parasite findings assume features akin to those of the blood of native children in hyperendemic areas Usually, between the eighth and tenth months after primary infection, there is a definite recurrence of fever and a reappearance of parasites in the blood, followed in a few days by recovery A few small doses of quinine then secure freedom from further attacks and from parasites Before the recurrence, the patient can be reinfected with the same parasite, but after 'spontaneous recovery' such patients are proof against reinfection This condition of immunity is inhibited by quinine therapy On the other hand, immunity to reinfection by *P vivax* confers no protection against *P falciparum* or *P malariae*, and complete immunity to reinfection by one strain of *P vivax* confers at best only a partial protection against another strain As immunity has hitherto been studied only as a mass problem among natives races, Col James suggests that the development of these findings should be carried out by field workers

Cases are recorded in which the expected malarial attack was six months or more late Since infection is desired early in malaria therapy, such cases are rare in induced malaria, but it has been possible to study twelve in which from 28 to 45 weeks intervened between infection and attack In one of these the patient had been infected with quartan fever when, nine months after infection with tertian, the benign type developed unaffected by a long attack of quartan followed by a curative course of quinine

If a distinction is made between the return of fever within eight weeks of recovery from a primary attack (recrudescence) the return between 8 and 24 weeks (relapse) and the return later than 24 weeks (recurrence), about half the patients infected by mosquito bite have one or other of these manifestations, the other half none Recurrence was found to occur within 27 to 39 weeks of primary infection, and all of the cases which 'recurred' in the twenty seventh week became ill on the 190th to 194th day after their blood became free from parasites after their primary attack This relationship led the investigators to construct a graph representing the history of 107 cases referred to the same starting-point The resemblance between this graph and representations of the seasonal clinical incidence of benign tertian malaria in northern Europe suggests that the 'spring rise', about which so much has been written, is due not to any climatic circumstance but to recurrences in persons who had their primary attack in September, with primary attacks in persons whose infection in September remained latent throughout the winter

Observations on prophylaxis by quinine support those made by Yorke and Macfie Quinine taken prophylactically will not prevent infection, but this is different from saying that it will not prevent clinical attacks Whether persons who have to live in a malarious place would be better advised not to take a daily dose of quinine but to wait until they get a true malarial attack which would be adequately treated by quinine, or whether they would be better advised to take a daily dose suppressing the outward clinical manifestations of the disease in order to 'carry on' during periods of moderate fever and indisposition, are questions to be answered differently in different cases The daily dose taker gains little or no immunity, and a period of exceptionally hard work is likely to determine a more severe attack than he usually suffers Large doses (30 gr) of quinine given at any time during the incubation period have no effect, a single dose of 5 gr after five or six paroxysms stops the fever but permits a recrudescence within a fortnight, a small dose (5 gr) given later and repeated daily for a few days cures 50 per cent of cases Existing practice would be revolutionised by adopting the indications afforded by these facts, but it would be unjustifiable to withhold quinine in a case of malignant tertian malaria later than the first discovery of parasites in the blood

Obituary

PROF W D HALLIBURTON, F R S

IN a nursing home at Exeter, William Dobinson Halliburton passed away, peacefully, on the evening of May 21 With his death the physiological world loses one of its most outstanding personalities, King's College one of its most loyal friends, and those who knew him, one who occupied, in their affection, a place it will not be possible to fill For Halliburton was unique To many is given knowledge, to many also the power to impart it A few have the intuitive faculty of investigating the fundamentals of their subject and of guiding the steps of others in the uncharted pathways of original research How restricted is the number who combine these attributes with patience apparently unlimited, calmness in times of stress, encouragement when disappointments came, and never, by word or deed, acted other than in the spirit of reasonableness Yet such was Halliburton

Born in London seventy years ago, educated at University College School, trained under distinguished teachers at University College and Vienna, Halliburton graduated in medicine and became Sharpey scholar and assistant in the Department of Physiology under Prof [now Sir Edward Sharpey] Schafer, following in this position MacWilliam, who until recently held the chair of physiology at Aberdeen Further academic attainments followed, he obtained his M D in 1884 and his membership of the Royal College of Physicians twelve months later

It was, however, four years after this that Halliburton's life-work began, for in 1889 he was elected to the chair of physiology at King's College, London, rendered vacant through the retirement of Prof G F Yeo, an appointment he held until his illness at Christmas 1922, an illness which, unfortunately, caused him to relinquish his professorship in the following July Since then his physical vigour has gradually failed and, while on holiday in his favourite Cornwall, a sudden relapse demanded his removal to Exeter, where he died

The present Department of Physiology at King's College is a tribute to the organising ability of Prof Halliburton On taking up his duties, he found the physiological laboratory situated in ill adapted premises in the basement But it was there, though handicapped in many ways, that some of his finest work commenced, and shortly after his appointment a move was made to the present position, where under his guidance it grew and prospered It was a source of gratification to him and to others that five years after his retirement, he was able to open extensions to his old department, extensions for which he had hoped and worked and, by his labours, justified

In his choice of staff and colleagues in research, Halliburton was singularly happy—one has but to name Dr [now Sir Charles] Martin, Sir Frederick Mott, T G Brodie, F S Locke, and Otto Rosenheim

Despite excursions into other parts of physiology, it was the chemical side to which Halliburton always returned, devoting much attention to the problems connected with the properties of nerve, of muscle, and of protein As an investigator his name is perpetuated in the pioneer work in these questions Halliburton made physiological chemistry his own It is largely to him that the present position of biochemistry is due By his earlier work and by his writings he laid the firm foundations of his subject, and his researches are now part of the heritage of physiology

Handicapped as he was in personal experimental work, his capacity for compiling and classifying information was little short of marvellous His "Text Book of Chemical Physiology and Pathology" (1891) is monumental, his "Handbook of Physiology" has completed nineteen editions, his "Essentials of Chemical Physiology" is now in its fourteenth In addition to these labours, at the request of the Physiological Society he became, in 1916, editor of *Physiological Abstracts*, a task which involved the issuing of a monthly précis of papers on biological subjects appearing throughout the world Almost unaided for five years, he not only edited and managed this journal, but also did the major part of the abstracting Other publications include "The Chemical Side of Nervous Activity" (Croonian Lectures, 1901), "The Biochemistry of Muscle and Nerve" (1904), "Physiology and National Needs" (1919) As contributions to original work, there appeared from his laboratory some three hundred papers by himself and by others He delivered the Oliver Sharpey (1907), the Goulstonian (1893), and the Croonian (1901) Lectures of the Royal College of Physicians He commenced and for several years compiled the invaluable section of physiological chemistry in the "Annual Reports on the Progress of Chemistry"

In 1891 Halliburton was elected a fellow of the Royal Society the degree of LL D was conferred on him by the Universities of Aberdeen and Toronto He was a fellow of both King's and University Colleges, senator of the University of London, member of the council of the Royal Society, and, in turn, vice president of the section of Anatomy and Physiology at the meeting of the British Medical Association in 1893 Twice, also, he was honoured by being president of Section I (Physiology) of the British Association

As a speaker Halliburton was supreme He brought to King's not only a scientific knowledge possessed by few, and a command of his subject coveted by many, but a facility of expression envied by all It was, indeed, a tragedy, in his later years of leisure, to see the gradual loss of this great gift

Halliburton's whole life reflected his personality Never physically strong, his ability to carry out the strenuous programmes that he did was due to the unflagging devotion of Mrs Halliburton, who until the end was untiring in her watchful care

Supplement to NATURE

No 3216 June 20, 1931

Habit The Driving Factor in Evolution *

By Prof E W MacBride, F R S

NO subject is of such perennial interest as evolution, for evolution means the gradual growth of one type of an organism into another as the generations succeed one another It is quite clear that if the possibility of this kind of growth be conceded for one type of organism it must hold good for all, since all, from the highest to the lowest, exhibit the same essential types of growth and reproduction Therefore the problem of evolution is the problem of the growth of all animated Nature, of which we ourselves form a part

One of the principal interests of zoology has been to endeavour to trace the course which evolution has actually pursued in the case of each particular group of animals It is as fascinating a problem as a cross word puzzle, with this great disadvantage, however, that it has been so far impossible to arrive at an agreement as to what is the correct solution

When this was first fully realised, interest in the problem dropped off In some quarters it was regarded as insoluble, and it was considered that the most contradictory solutions were equally likely Yet if the problem were given up, zoology would cease to be a science and be reduced to a lumber room of disconnected facts, as indeed was its condition during the eighteenth century

It is quite clear, however, that the problem of evolution is a secular one However it may have proceeded, its progress has been exceedingly slow and it is impossible to obtain direct evidence of the actual operation of an evolutionary process from observations made during the span of a human life Zoology shares this disability with geology, but geology is in better case than zoology, for geological structure, affecting as it does our obvious material surroundings, is likely to find a place in our permanent records, but no one in past ages is likely to have left minute descriptions of our common animals with which we might compare descriptions of their appearance to-day. All evidence for the occurrence of evolution is therefore indirect, for direct observation of living animals yields very little but confirmation of the old maxim that 'like begets like' Everything turns, therefore, on the validity and convincing power of this indirect evidence

The evidence chiefly relied on during the nineteenth century was similarity in ground plan of structure All animals possessing a back bone, for example, are built on the same general plan If all these animals had been evolved out of a common ancestor, this is what we should naturally expect to find, and these facts, although they do not prove evolution, are consonant with the theory that evolution has occurred Of course, if fish, amphibians reptiles, birds, and mammals all have grown out of one common stock, then the rule of 'like begets like' must have suffered exceptions, but this difficulty is got over by assuming a principle of 'variability', a principle which I shall discuss later

Further research into comparative anatomy has shown, however, that 'similarity in ground plan' does not always imply community of descent The muscles of fish and of the lower amphibia are divided into similar segments repeated in a line one behind the other, and so are the muscles of the common worms, but the view that worms and fish owe their similarities to descent from a common ancestor has now been given up by most zoologists It was, however, passionately advocated for at least a quarter of a century by the late Dr Dohrn, the founder of the Zoological Station at Naples Its disrepute is largely due to the assumptions which it involves if it be true, then worms must have given up their original mouth and invented a new one on the opposite side of the body in order to become vertebrates, and the main divergence between the supporters of this and rival theories of vertebrate descent depends on the view which their respective supporters take of the relative 'probability' that a new mouth would have been substituted for an old one, or that segmented muscles should have been evolved independently in two cases

* Royal Institution Discourse delivered on June 5

If variations occur sporadically in all directions 'by chance' for no assignable reason, if indeed, as the Bishop of Birmingham suggested in a recent address on "Heredity and Predestination", 'genes' come 'aus der Ewigkeit" and evolution depends on the chance correspondence of one of these genes with the needs of the animal, then the question of the acceptability of one theory of a particular descent over another is ultimately a question of the powers of imagination and credulity possessed by the theoriser

If, however, as most of us who have looked into the question agree, evolution, if it has occurred at all, has been slow, and structure has been modified in accordance with the demands of function, then we must look for evidence of a more satisfying kind than mere agreement in ground plan of structure So far as I can see there are three sources of evidence open to us, and only three We shall examine them briefly in turn

The First Proof of Evolution

(1) A species of animal is defined as an assemblage of individuals resembling each other closely, except so far as differences connected with age and sex are concerned, and crossing freely with one another and producing fertile offspring

Now if we examine wide ranging species the members of which do not wander about much, we find that all such species are divisible into local races, each race inhabiting a circumscribed area The members of each race differ from those of the next race in minute characters such as colour and the proportions of the limbs and trunk, etc No one has ever questioned the assumption that these various races have been evolved or developed out of a common stock, even the theological opponents of Darwin, who assumed that the Almighty had created every species independently, admitted this But subsequent research by naturalists has shown that there is no hard and fast line to be drawn between the differences that separate races and those that divide species There is, for example, a squirrel ranging all over tropical Africa known as *Heliosciurus* This varies a great deal in colour, and systematists had classified these colour varieties as distinct species But Mr M A C Hinton, after the examination of an enormous amount of material, has come to the conclusion that all these supposed species are merely local races of the same widely distributed species It is assumed, of course, that members of distinct species will rarely breed together, and that when they do so they produce infertile hybrids, but that when members of distinct races breed together they will produce numerous fertile offspring

In very few cases has this test been applied, however, we *guess* that two assemblages are distinct species, because when they come into contact with one another in Nature they keep distinct from one another, and in those cases where the experiment has been tried they are often mutually infertile But suppose we are dealing with two very similar groups of animals, one in Europe and one in America, and we regard each group as a distinct species, how shall we discover whether they are mutually fertile or not? In fact, it appears, especially from the researches of Dr Goldschmidt, who bred together members of the different geographical races of the Gipsy moth (*Lymantria dispar*), that there is no absolutely sharp division between sterility and fertility, but that there is every grade of fertility, with the zero limit at sterility

I have said that the division of the species into local races is only found in species which do not wander much Where there are extensive migrations either in search of food or to accustomed breeding places, members of the species drawn from all localities mingle together and no local races are formed Dr Johan Hjort has shown that an adult cod in the North Sea may travel as far as 2000 miles in one year to and from its breeding place No better example of the contrast between a stationary and a migratory species could be imagined than that between the so called viviparous eel, which is a blenny, and the true eel The true eel when fully grown is a fresh-water fish Its ally, the conger eel, haunts the sea, but is only found in shallow water close to the shore The true eel lives in rivers and ponds for several years, eating voraciously and growing enormously in size When fully grown, the desire to migrate to the sea overcomes it If it is in a river, it swims downwards to the mouth, if it is in a pond, it emerges at night and wriggles over the moist grass until it reaches the nearest stream and then resumes its journey to the sea I once surprised an eel in this migration, it was wallowing in a mud puddle in a field a few yards from the edge of a Cornish sea cliff No doubt as soon as darkness fell that same evening it would gain the edge of the cliff and make the great adventure True eels are found in all the rivers of Europe and North Africa, from the White Sea to Morocco, and also in the rivers flowing into the Mediterranean Yet if a sample of eels be gathered from any of these rivers and compared with a sample from any other, no difference can be observed between them It is true that the indi

viduals in each sample differ slightly from one another, some have a few more vertebræ in the backbone than others, but these differences are found equally in all samples

The reason for this uniformity of type became clear when Johannes Schmidt discovered the life history of the eel When eels reach the sea they all swim to the same breeding place, a spot situated in the Atlantic Ocean a short distance south of the Bermuda islands There they spawn, the females shedding the eggs and the males the sperm into the sea at random, where their union is left to chance, and thereafter the adults die Thus it comes about that the eggs of an eel from Morocco can be fertilised by sperm from a male from the North Sea, and if local conditions tend to produce local races, this tendency is neutralised by the constant crossing of the germ cells of individuals coming from different places The fertilised eggs develop into flattened semi-transparent larvæ with white blood utterly unlike the parents and they take three years to reach the streams from which their parents came

Contrast with this condition of affairs the habits and life history of the viviparous eel In this fish, the eggs after fertilisation are retained inside the oviduct and there develop into little replicas of their parents, ready to take up the parental life as soon as they are born They do not move far from their birth place, but form communities which interbreed chiefly with each other, and these communities show slight differences in structure from each other, even when as in Denmark they are separated from each other by distances so small as fifteen miles For example, a community living at the mouth of the Lym fiord differs slightly from one living farther up the fiord

Now no one will maintain that these differences have been specially created, all agree that they have arisen out of something in the local conditions The important point to note is that they are functional differences The eels from the mouth of the fiord are longer and slimmer than those living higher up, this difference in shape is a difference in the organ of locomotion, namely, the tail, which makes up two thirds of the fish (Fig 1) The fish near the mouth of the fiord go out into the troubled waters of the North Sea for their food and have to swim more strongly than their sheltered neighbours in the fiord Hence the difference in structure is correlated with a difference in habit If, then, these minute differences are the first steps in secular evolution, we may say that they demonstrate that ***habit is the driving force of evolution.***

THE SECOND PROOF OF EVOLUTION

(2) The second type of evidence is derivable from the remains of extinct animals, that is, fossils But only certain portions of this evidence are really convincing It is possible to take a series of fossil fish of different ages gathered in different localities and to arrange them in a series in the order of their supposed ages, and then to say that the series proves that evolution has gone on in a certain way It may be so, but it is always open to the objector to deny that the older members of the series are really the ancestors of the younger Some palæontological theories are based on series like this, but I have always been extremely sceptical as to their value I have harboured the suspicion that the younger fish in such series may have been

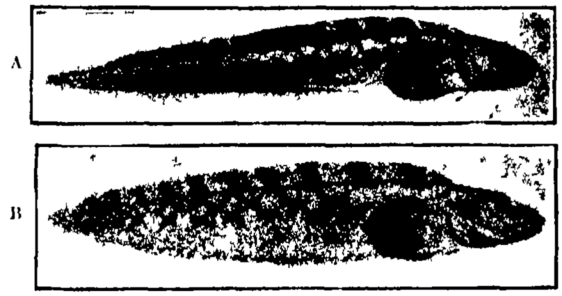

FIG 1 The viviparous eel (*Zoarces*) A The long slim open sea form B Shorter fatter form from enclosed waters

derived from fish contemporaneous with the older ones but as yet undiscovered

There are, however, certain exceptional cases in which a whole series of rocks in one and the same locality is full of the remains of the same kind of animals from top to bottom and where as we proceed from the older to the younger layers a slow modification in the structure of a particular animal can be seen, until, if we compare the youngest with the oldest layers, we seem to be dealing with quite a different species, though the difference between the specimens found in two contiguous layers may be so slight as to be inappreciable In cases like this, no doubt is possible that we are dealing with the same race of animals, which is undergoing slow modification, and these successions are known as *lineage series* The conditions for the preservation of such a lineage series are the persistence of a uniform deposition of silt in quiet waters in the same locality for vast periods of time The best two cases of such series known to me are the rocks in the western States of North America exposed in the sides of the Grand Cañon, and the English Chalk

In North America, the rocks are the beds of silt deposited by the annual floods of a great river

which originated in a large inland lake like the present Lake Superior Every year some of the animals grazing on the grass of the meadows bordering the river were drowned and their bones embedded in the silt In this way the whole story of the development of the camel and the horse has been elucidated, and, comparing the remains of these animals found in the lower beds with those in the upper, we can see the ancestors of the camels changing from four-toed quadrupeds into creatures like deer and thereafter into the splay footed modern camel The teeth of the earlier forms are in a complete series and the back teeth are studded with cusps Such teeth are found at the present day in animals which live on soft, succulent food As time goes on the cusps become connected by longitudinal ridges and the teeth are thus converted into mills suitable for grinding the harsh herbage of the steppes In the case of the horse we can begin with tapir like creatures with four toes on the fore feet and three on the hind feet and pass by an infinite gradation of stages to creatures with a single toe on both fore and hind feet like the modern horse The teeth pass from a condition with cusps to a condition in which the cusps are connected by ridges, but these ridges run obliquely across the tooth, not along it as in the camel

Now all these changes, both in the camel and the horse, take place with great slowness and are correlated with changes in habit The early ancestors walked on swampy ground as the tapir does now, ground where the spread of four toes was needed in order to give them adequate support As the ground became harder and dried, more and more reliance was placed on the central toes, and the lateral toes dwindled The tapir to-day lives on exactly the same kind of food as is indicated by the teeth of the ancestors of the horse

The English Chalk originated as a deposit of calcareous mud in quiet sea water a considerable distance from land, so that it was unpolluted by sand and mud borne down by rivers In this mud lived and burrowed heart-urchins in most respects very similar to the modern heart urchin, *Echinocardium*, which burrows in the sands of the Firth of Clyde Our modern urchin constructs for itself a cave in the sand, the roof of which is supported by a crest of curved spines which the heart-urchin carries on its back The cave communicates with the surface of the sand by a vertical shaft The mouth is on the under surface of the animal, not in the centre but pushed towards one side It is crescentic in shape, with a greatly projecting lower lip called the labrum On the back of the urchin there are five impressions radiating from the centre which remind one of the petals of a flower (Fig 2) These impressions are each composed of a double series of transverse grooves On each groove sits a broad, flattened tentacle which acts like a gill this tentacle communicates with the interior by two pores, one at each end of the groove Through these pores, the tentacle communicates with an internal reservoir known as the ampulla The right and the left series of grooves are separated by a median bare space One of the petals is markedly different from the other four It is more parallel-sided and the grooves are fainter and more numerous From this petal are given off, not gills, but very long tentacles terminated by frilled discs These tentacles are thrust forth two or three at a time through the vertical shaft on to the surface of the sand Here they collect small animals such as baby mussels, pull them down the shaft, and transfer them to a ring of branched tentacles surrounding the mouth, the so called buccal tentacles, by which they are pushed into the gullet, and so the heart urchin feeds The gills are continually bathed in a current of fresh sea water, which is sucked down the shaft and made to flow over the gills by the action of certain ciliated spines

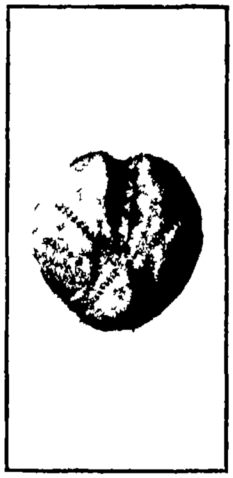

FIG 2—Denuded shell of the recent heart urchin (*Echinocardium*) showing the upper surface Note the grooved anterior petal

Now when we examine the chalk sea-urchins which are known as *Micraster*, we discover that they occur in certain places in countless numbers throughout a great thickness of strata, and we find that they slowly change their characters as we pass gradually from the lower strata to the upper The oldest *Micrasters* have the mouth circular in outline and entirely devoid of the projecting lip or labrum (Fig 3) The petals are short and are not grooved, and the anterior petal is not markedly different from the rest We interpret these features as meaning that these urchins, like the modern heart urchin, *Spatangus*, were only partially buried, the gills projected freely into the sea-water, and the tentacles from the anterior petal were comparatively short. The roundness of the mouth suggests that food was sought all round it from the sand on which the heart-urchin rested. As we pass upwards, the

mouth becomes more and more crescentic in shape, the labrum grows out over it and at the same time the anterior petal becomes more and more grooved This grooving indicates the gradual coming into function of the long tentacles as food gatherers Simultaneously the centre lines of the other petals between the two rows of gills become grooved and a sharp crest or ' carina ' is formed in the mid dorsal line in order to carry the spines which support the roof of the cave

All these changes are the result of a habit of burrowing deeper on the part of the sea-urchin As it sinks below the surface of the mud, it becomes necessary to hold the mud away from the gills, and so the crest or carina carrying the fan of curved spines is developed The buried gills require a more rapid current of clean sea-water over their bases and so the furrow in the centre of each petal becomes channelled out Every change in structure is correlated with a change in habit

For convenience, geologists pick out certain forms which occur at certain levels and constitute them types thus we have the zone of *Micraster cor bovis* But if we collect enough specimens, we find that these types are but arbitrarily chosen levels in an ever varying population Moreover, we find that the various characters, such as labrum, carina, grooved petals, do not change at the same rate in each individual In one, the mouth may be more crescentic but the petals less grooved than in another It is just as if the structure of each individual was responding to the change in its habits—but as if the different habits were not being modified at exactly the same rate in different individuals—in fact, as it has been dramatically

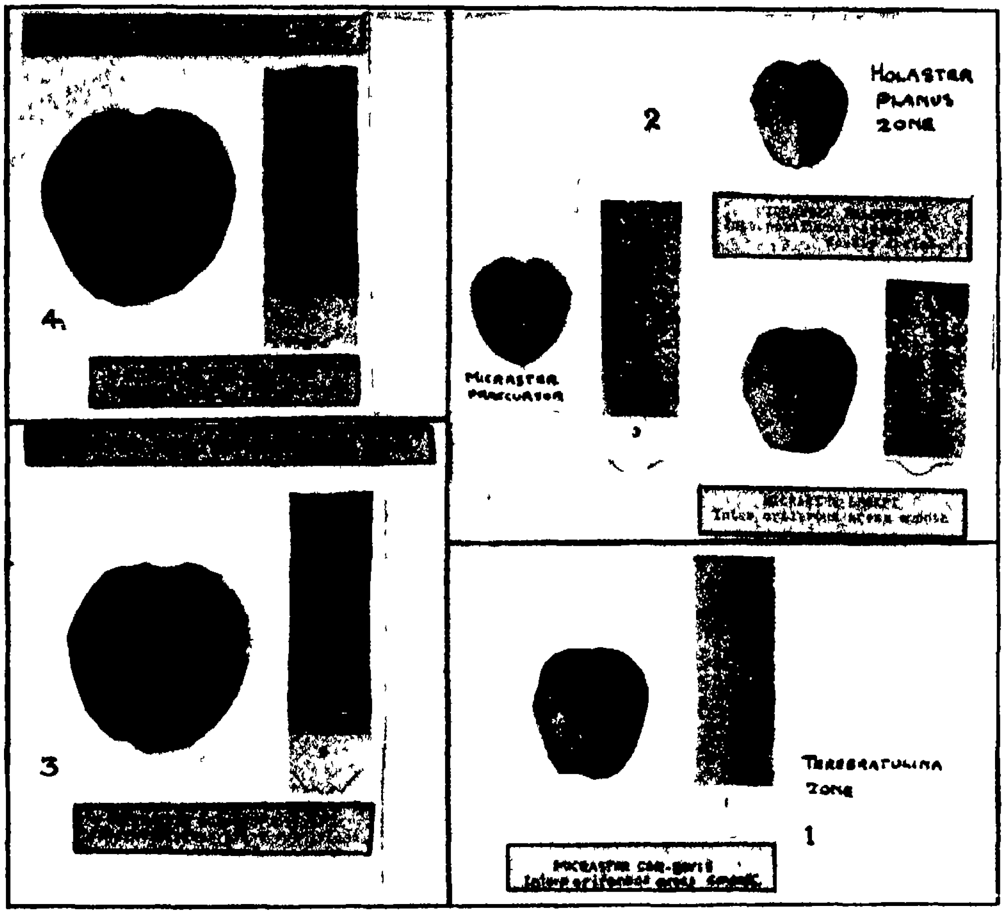

FIG 3—Four stages in the lineage series of the cretaceous heart urchin (*Micraster*) (1) is the oldest All show the upper surface (1) *Micraster cor bovis* (2) *Micraster præcursor* (3) *Micraster cor testudinarium* (4) *Micraster cor anguinum*

Changes in the interporiferous areas—On the upper surface of the sea urchin are five petal shaped tracts each formed of two rows of plates pierced by pores for the tube feet The middle region of each petal between the rows of pores is 'the interporiferous area In the lowest zone these areas are quite smooth, and the joints between the plates are not apparent In the following zones the areas undergo gradual change the successive stages being termed sutured inflated subdivided, and divided Thus in the highest zone the plates are divided by a median furrow, and are swollen and granulated

expressed by one of our leading palæontologists, it is as if an individual could have a new collar but last year's pair of boots

The evidence from lineage series thus confirms the conclusion derived from the study of local races that *change of habit is the driving force in evolution*

The Third Proof of Evolution

(3) The third class of evidence is much more disputable than the first two, but if it can be established that it is valid, it is of much greater importance, because it is far more wide reaching This evidence is the life history of the individual, which, according to the so-called 'biogenetic law' of Haeckel, is a 'recapitulation' of the history of the race This theory, at various times, has been heavily attacked It has been asserted that there is no inherent reason why the individual in its development should rehearse its ancestral history, and that in many cases it is impossible to imagine a functioning adult animal at all similar in character to the embryo

The assumption that the animal does repeat its ancestral history involves a theory of the time at which 'variations', that is differences between one generation and the generation which preceded it, manifest themselves Geneticists are prone to assert that variations are due to chemical changes in the egg and that this changed chemical composition manifests itself as a changed growth at all stages in development Eimer, however, the inventor of the term 'orthogenesis', maintained on the contrary, as a result of his detailed comparison of allied species, that new characters appear only towards the completion of growth and then first in males The dispute has arisen, as so many disputes arise, from the confusion of two different types of phenomena The geneticist is considering the abnormal, non functional and monstrous deviations of growth shown by our domesticated animals, these are due to interferences either with the egg or with the very young germ, they often, but not always, show themselves at the beginning of development, and the individuals showing them are always physiological weaklings as compared with the typical animals That these 'sports' or 'mutations', as they are called, are really due to chemical changes in the protoplasm, I am by no means ready to concede, the evidence available points rather in the direction of their cause being specific weakening of the powers of growth It is a remarkable fact that when these weaklings are returned to normal conditions and still are able to survive, their offspring revert in a limited number of generations to the normal type The systematic zoologist, on the other hand, deals with specific differences and Eimer is right when he says that these are manifested only at the end of growth, the youthful forms of allied species are notoriously so like each other as to be almost impossible of distinction

If we compare two species belonging to the same genus, one of the generalised type common to the tribe and the other of a specialised type, it will be found that the youthful form of the specialised type resembles closely the generalised type If we reject the doctrine of special creation and adopt the hypothesis that the two species have been developed out of a common ancestor, then it follows inevitably that the more specialised repeats, in its later development at least, the history of the race We can only have definite proof of this biogenetic law when we have independent means of knowing what the ancestry of a particular species has been, and, as has already been pointed out, this is possible in only a few cases, and the knowledge thus attained throws light only on the latest phases of racial history But the developmental history of all the higher animals begins with the egg—which in its essential structure is an amœba like protozoon—and therefore this development should present in shortened and simplified form the whole story of the race from its emergence from the protozoon level to its culmination in the adult form of the species We have no certain means of testing the accuracy of the earlier part of this record, but if we can bring strong evidence to show that the later phases do really represent ancestral structure, and if we can by comparative embryology elucidate the secondary causes which have modified the ancestral record, then I think we are justified in the faith that the whole development is a story of the evolutionary history of the race

Larvæ and Embryos

Now one of the most important things to notice is that the development exhibits two phases, both of which are always present but which are of very different relative duration in different species These are the *embryonic* and *larval* phases In the embryonic phase, the young creature is sheltered from the outside world, but in the larval phase, it leads a free life, seeking its own food and avoiding its enemies The latest phases of development are always larval, for no animal is born exactly like the adult condition The earliest phases, on the contrary, are always embryonic, because no egg is

ever cast naked on the world, every egg is sheltered for a longer or shorter time either inside an egg membrane or the mother's body

Now it is easy to show that the larval mode of development is the primitive one, of which the embryonic is a secondary modification For the organs of the larva are used, whereas those of the embryo are non-functional Thus there is a toad called *Hylodes* which lives in the West Indies and frequents localities in the damp undergrowth which are far from water This toad lays large eggs from which hatch out minute fully-formed toads If, however, one of these eggs be opened about half way through its development, there will be found therein a tadpole with fully developed tail and internal gills like those of the tadpole of the ordinary toad which lives in water Therefore if we are seeking the original meaning of development, we must concentrate our attention on species with a long larval development

When we do so, we find in many cases, notably in the life-histories of the Crustacea, that the larval phase is broken up into a series of sub phases or 'instars', and that during every one of these the larva has a distinct set of organs and corresponding habits, so that the primitive type of development consists of the coming to the surface of a series of habits, and when a species deviates from the habits common to the order in the last phase of development, it exhibits the habits typical of the order in its younger phases Of this we may cite one example which is familiar to many From the egg of the common shore crab, *Carcinus*, there hatches out a small shrimp like creature known as a *zoaea* This larva has a rounded and shortened fore part of the body known as the cephalothorax and a long thin hinder part divided into six segments known as the abdomen The cephalothorax has a spike projecting upwards from the centre of the back, and also one in front which is known as the rostrum At the sides of the rostrum are two large stalked eyes, and behind these there are two pairs of short feelers Beneath is the mouth and at the sides of this are situated three pairs of jaws or 'gnathites', which are practically identical with those of the adult crab Behind these jaws we find two pairs of comparatively long forked legs, the so-called maxillipedes This list comprises all the limbs which the zoæa possesses By using the maxillipedes as oars it rows itself vigorously about, grasping at any food which comes within its reach by means of its jaws, and it employs its abdomen as a rudder

Like all Crustacea, the zoæa is enclosed in a stiff horny cuticle or shell which impedes growth Nevertheless, growth goes on, small buds appear at the sides of the segments of the abdomen prefiguring swimmerets, and behind the maxillipedes other buds appear, the first indications of the normal legs of the crab The zoæa moults four times, and after each moult comes a short period of unimpeded growth during which the leg buds increase slightly in length but the abdominal buds become fully developed swimmerets Then comes a fifth and critical moult and the larva changes into a *megalopa*, which sinks to the bottom and has different habits For now it has legs behind the maxillipedes with which it can crawl, and it takes on habits like those of the shrimp Like the shrimp, it can still occasionally swim, using for this purpose, however, the abdomen with its swimmerets and not the maxillipedes

After a brief period of this kind of life, the megalopa undergoes another moult from which it emerges as a creature with a broadened cephalothorax but a reduced abdomen, no longer used for swimming but tucked underneath it, in a word, it has become a crab But the crab has not yet attained the complete features of the adult crab For one thing, the abdomen retains a full set of swimmerets It grows older and bigger, undergoing a series of moults At last, there comes a crisis when it assumes the full sexual characters of the adult These characters are indicated by far-reaching modifications of some of the swimmerets It might have been expected that as moult succeeded moult the swimmerets would gradually change into sexual organs When the crisis arrives they are re-absorbed into the body, their outer horny shells are cast off in the moult Underneath the next shell they re develop as buds, which grow into the shape of the sexual organs, and after the next moult they appear in their fully developed form

This history shows clearly the stuff of which development is made, we see a succession of 'powers of growth' coming into action one after another, each set of growth powers gives rise to a corresponding set of organs, and each set of organs corresponds to a new set of habits Development can thus be analysed into a superposed series of habits, and thus it affords another confirmation of the theory that *habit is really the governing factor in evolution*

The Effect of Acquired Habit on Heredity

We have yet to face the really fundamental question How does habit govern evolution?

Does habit change first, and do the changed habits produce the modified structure, or do structure and habit both 'vary' in all possible directions, and when the right habit and the right structure 'happen' to coincide in some fortunate individual, is this individual 'naturally selected'? In a word, does Darwin's theory of evolution by natural selection cover the case of correlated changes in habit and structure?

Now, in a sense, the theory of natural selection does cover this, and all other possible modes of evolution For if evolution has gone on at all, the powers of growth of one generation must have become altered as compared with those of a previous generation, and this alteration is what is known as 'variation' Again, if evolution has occurred, the individuals which have evolved must have continued to live, that is, they must have survived To say that an individual has been 'naturally selected' is merely to say that it is there Consequently the theory of evolution by natural selection is worse than a fallacy—it is a truism, it pretends to give an explanation which turns out on examination to be no explanation at all, but a mere form of words It is obvious that the real problem is glossed over, it is hidden in the word variation or *change* Until we have explained that, we have not really attacked the problem of evolution at all

Darwin implicitly assumed that inheritable variations in all directions turn up 'at random', so that the right combination is always there to be 'naturally selected' If this were really so, we should have to investigate the causes which produce these 'random' variations, for 'chance' or 'contingency' is no scientific explanation But the so-called pure line investigations prove conclusively that Darwin's assumption is wrong In phanerogamous plants, in Crustacea and in Protozoa, it has been proved that if we raise a brood from one parent only, either by self fertilisation as in the case of the plant, or by parthenogenetic reproduction in the case of the crustacean, or lastly by the asexual process of fission as in the case of the protozoon, the members of the brood will differ from each other slightly in size and proportions, but the shorter individual will give rise to a brood of grandchildren as long as, or even longer than, those of the longer individual These individual differences, or 'fluctuating variations' as they are called, are due to differences in nutrition and are not inheritable

If we abandon, then, the theory of random variations, we have to face the only alternative left, namely, that change of habit produces change of structure This is the theory of evolution put forward by Lamarck, as can be shown by quotation from his "Philosophie Zoologique" "Every fairly considerable and permanent change in the environment of any race of animals works a real alteration in the needs of that race Every change in the needs of animals necessitates new activities on their part for the satisfaction of those needs and hence forms new habits Every new need necessitating new activities for its satisfaction, requires the animal to make much more frequent use of some of its parts which it previously used less and thus greatly to develop and enlarge them A more frequent use of any organ gradually strengthens, develops, and enlarges that organ, whilst the permanent disuse of any organ imperceptibly weakens and deteriorates it, and progressively diminishes its functional capacity until it finally disappears All acquisitions and losses wrought by Nature on individuals through the influence of the environment in which their race has *long* been placed and hence through the influence of the predominant use or permanent disuse of any organ, all these are preserved to the new individuals by reproduction"

This theory is what is termed 'Neo Lamarckism' in order to distinguish it from the full evolutionary theory of Lamarck, for Lamarck believed that the principal factor in evolution was a sort of urge towards perfection which was inherent in living things, and that this urge was modified and even diverted from its course by the effects of the formation of new habits Now, in order to prove the truth of Neo Lamarckism, it is necessary to bring evidence that the formation of habits in one generation affects the next generation We must also try to show how this is possible, remembering that each member of the new generation begins its existence as a tiny germ cell, and that whatever influence is carried over from the previous generation must be somehow embodied in this cell Of course, it is generally admitted that the formation of a new habit modifies the growth, and therefore the structure, of the generation by which it is formed We are all familiar with the enormous arms of the prize fighter, and the greatly strengthened legs of the professional dancer But, to many people, it is difficult to believe that the strengthening of one particular organ should so affect the germ cell that in the new animal produced by it the same organ should be strengthed as was strengthened in the parent

Perhaps the best piece of evidence so far obtained

is that which emerges from the experiments of Dürkhen These experiments lasted five years and the animal dealt with was the common white butterfly, *Pieris brassicæ* Dürkhen discovered that if the caterpillars of this larva were reared in boxes provided with lids of orange tinted glass, they would metamorphose into pupæ the pupal coverings of which, instead of being coloured dirty white as in the normal pupa, were transparent Since the blood of the pupæ is coloured green, this blood shines through the transparent cuticle and the pupa appears to be green The pupæ were allowed to live until the white butterflies escaped from them These butterflies were carefully preserved in large cages exposed to the air and light but protected from the attacks of birds by a double belt of close wire netting They were fed on sugar and water, and after a week or two they paired and laid eggs, which were carefully preserved Then these eggs were reared up into caterpillars Half of these caterpillars were subjected to the same treatment as their parents, but half were reared in ordinary daylight The results obtained were as follows From the original generation of caterpillars 66 per cent of green pupæ were obtained, from the second generation reared under orange light 95 per cent green pupæ resulted When the offspring of the first generation of green pupæ were reared in ordinary daylight, 34 per cent of green pupæ resulted The normal percentage of green pupæ found in ordinary cultures where no coloured light was employed was 4 per cent These experiments show clearly that when a habit is acquired by one generation, a second generation exposed to the same conditions acquires the same habit more quickly and thoroughly, and that when the offspring of a generation which has acquired a peculiar habit are returned to normal and typical conditions they still show the effects of the habits acquired by the parental generation

These experiments were repeated by Heslop Harrison on the allied species *Pieris napi*, the turnip white butterfly In this species, the first generation of caterpillars reared under orange glass gave rise to 94 per cent green pupæ, whilst the second generation reared under the same conditions gave also 94 per cent green pupæ, thirty of these second generation caterpillars reared in daylight all gave green pupæ The percentage of green pupæ found in normal cultures was, however, higher than in *Pieris brassicæ*, reaching 20 per cent

Heslop Harrison carried out another series of beautiful experiments to show how an ingrained habit is inherited There is a gall fly, *Pontania salicis*, which normally lays its eggs in a particular species of willow (*Salix andersoni*) Harrison found that by hatching the insects out of the galls of this species and letting them loose in his garden, they could be forced to lay their eggs on another species of willow (*Salix rubri*) when the first species was not available During the first years there was a heavy mortality and only a few of the gall flies succeeded in establishing themselves on the strange willow, but when the experiment had lasted for five years Harrison reintroduced the original species of *Salix* into his garden, but the saw flies continued to lay their eggs on *Salix rubri*, to which they had been accustomed The acquired habit had therefore become hereditary

Perhaps the best example of the inheritance and transmission of an acquired habit is afforded by the experiments of Metalnikoff on *Galleria*, a moth the caterpillars of which feed on beeswax If the caterpillars of this species are reared in an incubator at a temperature of 30° C they will pass through their entire development in a period of 6–8 weeks, so that as many as six or eight generations can be reared in a year The caterpillars are extremely susceptible to attacks by the cholera bacillus, but, as is well known, a vaccine immunising against the attacks of this bacillus has been prepared, and if this vaccine is injected into the caterpillars when very young they resist the toxins produced by the bacillus Metalnikoff began his experiments with a brood of caterpillars which were the offspring of a single female He 'immunised' half of these with the vaccine and then inoculated the whole brood with the cholera bacillus After three or four days the survivors were counted and allowed to develop and become the parents of the next generation The same procedure was adopted with the next generation This generation may be called the first filial generation and its offspring is then the second filial generation None of the unprotected members of the first or second filial generation survived, but of the third filial generation 30 per cent survived In the sixth filial generation the proportion of survivors had risen to 42 per cent, and in the ninth filial generation to no less than 75 per cent

Metalnikoff remarks that the reason why previous experiments designed to test the theory that acquired habits are inherited had given negative results was that the experimenter had been content to rear two or three generations only "Time pays no attention to experiments in which she is left out of account"

Entomologists have long been familiar with what are termed biological races within the species By

this is meant races which nearly or entirely resemble each other in structure but differ in their habits, notably in the species of plant or animal which they attack The same kind of races are encountered in other groups of animals Dr Goodey has described them in the case of nematode worms Thus *Ascaris lumbricoides*, a worm about six inches long, is found both in the human intestine and in that of the pig Nevertheless, if the eggs of the human *Ascaris* are eaten by the pig they fail to develop in its intestine In Trinidad, a large proportion of the pigs are infected with *Ascaris lumbricoides* but the pig keepers, who are principally Negroes, suffer very little from this parasite, although, when one considers their habits, their food must be constantly polluted with the eggs of this worm

Again, the nematode, *Heterodera schachtii*, attacks beetroot The male remains in the earth, but the female bores into the plant and swells up to the size of a lemon seed which it resembles in shape and appearance In Germany there is a race of *Heterodera schachtii* which attacks the potato In this race the female when it swells assumes a spherical form It is very difficult to get this race to live in the beetroot, but by planting beetroot for three years running on land infested with the potato parasite, this was finally accomplished The females, although descended from the potato race, when they succeeded in maintaining themselves on the beet assumed the form of a lemon seed

Goodey attributes the formation of these biological races to 'food memory' By this he means that the female transmits to its offspring some substance which induces them to seek out the same kind of plant as that in which it lived He thinks that this is not quite the same as the inheritance of acquired characters But it is inherited habit and, as has been pointed out, this is what Lamarck meant by the inheritance of acquired characters habit changes first and structure follows only long afterwards

Dr Thorpe, in an article entitled "Biological Races in Insects" (*Biological Reviews*, vol 5), has given numerous examples of these races From his interesting article we select the following cases The louse which infests the human hair (*Pediculus capitis*) differs slightly from that which hides in the clothing (*Pediculus corporis*) in colour and shape (Fig 4) Nuttall bred the head louse, *Pediculus capitis*, for two years in boxes and found that it was completely changed into *Pediculus corporis* *Hyponomeuta*, the small Ermine moth, attacks the apple, the hawthorn, and the blackthorn The forewings of the moth are said to 'vary' in colour from dark grey to pure white, but it appears that the 'varieties of colour' are correlated with the plant attacked, for the white variety was found most frequently on the apple and the dark-grey on the hawthorn When larvae taken from the hawthorn were allowed to pupate in cases containing both apple and hawthorn, they laid 911 eggs on the hawthorn and 237 on the apple Thorpe remarks that the offspring of a generation reared on one plant and forced to feed on another will produce a third generation which will prefer the second food plant to the ancestral one, but will not entirely pass over to it when offered a choice of plants, so that the change from one set of habits to another is progressive, not effected at once as it should be if it were merely a case of 'memory'

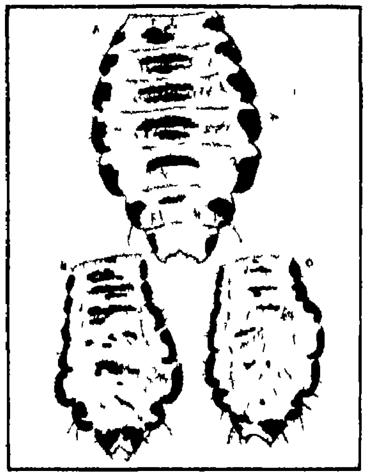

FIG 4 – The abdomens of varieties of the human louse (*Pediculus humanus*) A Body louse B and C Head louse

Another group of animals in which the production of new races by the formation of new habits is going on is the fishes which inhabit the torrential hill streams of India These fish which have been beautifully described by Hora, have evolved modifications of the ventral surface which enable them to cling to stones and avoid being swept away by the current We may select the carp like fish *Garra rupeculus* for special description Of this fish, Hora collected a large number of specimens of varying sizes He found that when they were very small (13 mm) in length the mouth was nearly terminal and was bordered by its proper upper and lower lips As it grew larger, a so called anterior labial fold made its appearance, which in its growth pressed the mouth downwards and backwards and the true lip inwards Behind the true lower lip another fold, the posterior labial fold covered over with papillae, makes its appearance This is crescentic, with the concavity turned backwards, and between the arms of the crescent a disc-like area of callous skin appears which the fish presses against the stones so as to act like a sucker The lateral extremities of the true posterior lip grow backwards and form lateral

borders to the sucker A tuberculated ridge of skin forms its hinder margin These stages, which Hora believes to be all growth stages of *Garra rupeculus*, are paralleled by the adult stages of other species of *Garra* The differences in development of the sucker are correlated with slight differences in the velocity of the current, and hence in the efforts which the fish has to make to hold on to the substratum

If we sum up all this evidence, we arrive at the conclusion that these biological races owe their origin to the inheritance of acquired habits, and in them we see the very first stages in evolution I cannot sympathise with the remarks made by Dr W T Calman in his address to Section D (Zoology) at the meeting of the British Association at Bristol in 1930 Dr Calman stated that the cases adduced to prove the inheritance of acquired characters concerned characters so slight and fugitive that they could have played no effective part in evolution Since, as all admit, evolution has been a very slow process, it could only be the very smallest steps in it which could be demonstrated during the period of observation open to a single observer Many people appear to think that in order to prove the inheritance of acquired characters, it would be necessary to show that when a structure had been changed by the exposure of the animal to a new environment during one generation, the same structure should be inherited in full strength by the next generation when the new environment had been changed back into the old and typical one This shows a complete misunderstanding of the real state of affairs When a structure changes owing to the action of a new environment, this is because it responds to the change by a new rate of growth, if the offspring are replaced in the old environment, this means that they come again under the influence of that environment, and their mode of growth tends, of course, to respond to the old and typical environment To prove that the habits and mode of growth acquired in one generation do affect the next, all we require to show, and all we could expect to see, would be that there was an *intensification* of the effect when the exposure to the new environment was continued for several generations, and a *lag* in the resumption of typical characters when the *offspring of individuals which had been exposed* to the new environment were replaced in the typical environment These expectations are amply borne out by Dürkhen's experiments on pupæ and Nuttall's experiments on the louse, to name only two examples

The Mode of Transmission of Acquired Habit

Even if we succeeded in showing that the characteristic features of allied species were correlated with the habits of each particular species, many people still feel a hesitation in admitting that the habits have caused the characters To revert to the case which has just been considered they would ask, how can the fact that the *Garra* fish in one particular place have to press their discs more tightly against stones, and thus enlarge them, so affect their germ cells that these, when they develop into little fish, will have larger discs? Is a picture of the parent repeated in miniature in the germ cell? Even if we could admit this, we might ask how the germ cell picture was altered when the parent was altered

Now the study of embryology, and in particular of experimental embryology, affords, as it seems to me, a satisfactory answer to these conundrums Whatever the embryo is, it is not a machine, that is, as Driesch expressed it it is not a constellation of parts in fixed relations to one another, and this is the only exact meaning that can be given to the word 'machine' It begins as a single cell and this multiplies by division into a number of cells, and *in each cell slumbers the power of developing into the whole* The nucleus as is well known, is the centre of the growth powers of the cell, but what a particular cell will develop into depends not on its inherent capacities but on its position in the whole It is dominated by the whole, and this is what Driesch meant by 'entelechy' The early development of sea urchins affords beautiful examples of this When the egg divides so as to form a blastula, a portion of this blastula can be cut off the remainder contracts so as to heal the gap and produces a small larva with all the organs developed but of reduced size Further, when the egg has divided into a few cells, the mutual positions of these can be altered by pressure so that cells that should be in front lie at the sides and vice versa, yet it develops into a perfect larva All the cells are equipotential But this state of affairs does not continue After a time the gastrula stage supervenes, when one pole of the blastula flattens and is pushed in like a finger, so that the rudiment of the gut is formed If just before this stage supervenes the top half of the blastula is cut off, this top will grow into a new blastula, but will develop no further, whilst the bottom half will heal up and proceed with its development and form a perfect larva

Later in development the front cœlomic pouch on the left side gives off a little bud which grows into the water-vascular ring-canal of the adult sea-urchin From this canal all the beautiful tentacles of the adult grow out This bud modifies all the tissues in its neighbourhood The skin covering it gives rise to a crown of beautiful pointed spines Where the posterior cœlomic vesicle is overlapped by the bud, this vesicle gives rise to the chisel like teeth of the urchin Under stimulation of the growth of the larva the front cœlomic pouch on the *right* side may also give rise to a water vascular bud When this takes place it transforms all the tissues of the right side of the larva, diverting them from their normal course of development and transforming into replicas of the tissues on the left side of the larva

How have these changes come about? Since the nuclei govern the whole growth and metabolism of the cells, it can only be because the nuclei in a certain part of the embryo have emitted some new substance into the protoplasm which has altered its growth So that we are confronted with the paradox that the nuclei, which are alike and all of which possess all the powers of developing into the whole, when once the development of the whole has started, develop only portions of their powers appropriate to their position in the embryo and produce these powers one after the other in a definite order The most marvellous example of this has been described by Brachet The egg of the frog, he found, can be entered by as many as seven spermatozoa One of these unites itself with the egg nucleus—in a word, fertilises the egg—and then this double or zygote nucleus starts dividing and organising the protoplasm into cells But the other spermatozoa start doing the same thing, and as they are only half the size of the double nucleus, the cells which they form are much smaller and easily distinguished from those formed by the zygote nucleus Thus there may be no less than seven centres of cell formation in the egg, yet out of this medley is produced not a seven headed monster but a single tadpole

Just as the whole in development dominates and directs the growth of the parts, so, in reaction to the environment, the whole animal enters into the reaction and every part is co ordinated with every other part When, for example, a lion springs on its prey, every muscle in its body comes into action, some are contracted, others are relaxed, for it is not the individual organ which reacts to the stimulus but the whole animal The reflex actions of excised muscles with which human physiologists have chiefly occupied themselves give no picture at all of what goes on in the intact animal striving under the influence of what Lamarck calls its 'inner feeling', and Rignano its 'affectivity', to escape from its enemies or to seek its food or a mate

If we make the reasonable assumption that every such action has a reciprocal effect on the nuclei, and stores up something in them which is given forth when the action is repeated and accelerates and strengthens it, then we can make a provisional picture of the *modus operandi* of the inheritance of habit For since all the nuclei are potentially alike, any one of them may become a germ cell if it finds itself in the proper position in the developing egg, and the nuclei of the germ cells will receive, like the nuclei of the other cells, the after-effects of the animal's actions When the germ cells develop into the new generation, these deposits will become active at the corresponding period of growth of the embryo and will stimulate this growth If the habit continues for many generations, more of the deposit will be formed every generation with an increasingly powerful effect on growth The modified structure will be formed on ever slighter stimulus, until finally so much of the deposit is accumulated that the organ develops without stimulus at all, like the eye of the baby rabbit in the darkness of its mother's womb

In the light of this hypothesis, we see why development should be ultimately analysable into a superposed series of habits, and why in the last resort *habit should be the driving force in Evolution*

Printed in Great Britain by R. & R. Clark, Limited, *Edinburgh.*

Church Cottage, their home in Marylebone Road, was open house to friends of all ages In this oasis from London's rush, many sought both help and advice, none was refused Free from worry over the more material aspects of life, his help to those in straitened circumstances was often more than words Generations of students think with affection and speak with reverence of their old teacher and friend Childless himself, *they* were his ' boys and girls ' When he came to King's, our College was enriched, by his death the whole scientific world is made poorer

It is difficult to write truthfully about Halliburton without appearing to exaggerate His character, his scientific accomplishments, his nature, his industry, his very life itself, make him one we can but mourn and do no more than try to copy

J A HEWITT

DR RUDOLF MARLOTH

WE record with deep regret the death of Dr Rudolf Marloth, the distinguished botanist, who has been so closely associated with botanical work in the Union of South Africa Dr Marloth's profession was that of a consulting analytical chemist, but it is with regard to his botanical work that he is best known in the domains of science

On the foundation of the Botanical Survey of South Africa, he was appointed a member in the year 1918, but before that time he had gained a reputation as a botanist with a wide knowledge of the flora of the Cape region He was president of Section B of the South African Association for the Advancement of Science in Cape Town in 1903, and was president of the whole Association at Kimberley in the year 1914 He was also president of the Cape Chemical Society in 1913

Marloth was the author of many botanical works and in particular "Das Kapland", which was published in 1908 and gives a general phytogeographical account of the vegetation of South Africa This fine work is profusely illustrated, mainly from photographs taken by himself, for Dr Marloth was, among other things, an expert photographer and an acute observer of biological factors in relation to plant life Another monumental work is his "Flora of South Africa", planned to occupy four volumes, three of which have now been published, the first volume appeared in 1913, and this also was magnificently illustrated with both photographs and coloured plates This is not a 'flora' in the strict sense of the term, as only a portion of the genera and species is dealt with and the Gamopetalæ have not yet been published It is, however, a work which all those interested in the wonderful flora of the Cape region find indispensable for the proper study of the flowers of South Africa He also published, in the year 1917, a "Dictionary of the Common Names of Plants of South Africa" In this volume, some two thousand records of common names of plants found in South Africa are given, and the list is particularly useful to the overseas visitor, since the Dutch have common names for most of the more conspicuous and generally distributed plants One of his earliest works was his "Elementary Botany for South Africa", which was published in the year 1897

Dr Marloth travelled widely in Africa in the course of his duties as an analytical chemist, and had a wide circle of friends, particularly among the Dutch, who helped him considerably in his botanical studies In connexion with his work on the Botanical Survey, he collected together a fine herbarium, which was remarkably rich in the Euphorbiaceæ and other succulent plants belonging to the Cape Province The collection was rendered all the more valuable by the inclusion of photographs of these plants, giving their characteristic features in careful detail Such photographs in the case of 'fleshy' plants are of very great value to the botanical student, and his herbarium, which will pass to the National Herbarium at Pretoria, will be invaluable to botanists carrying on researches on the flora of South Africa

Dr Marloth was a man of great energy and a delightful companion in the course of a botanical ramble Having had an opportunity of spending some nine strenuous hours in his company on Table Mountain last November, one was able to realise the great extent of his knowledge of the Cape flora, and also his untiring energy as a walker, for despite his age, he was able to outwalk many a younger man His unexpected death will be a very great loss to botanical science, not only in South Africa but also to the world in general

A W H

PROF JAKOB ERIKSSON

JAKOB ERIKSSON, whose death, on April 26, we regret to record, was born in Hyllie, near Malmö, Sweden, in 1848 After a course of study at the University of Lund, he obtained his Ph D in 1874, and the same year was appointed lecturer (Dozent) in botany at the University A year later he was called to Stockholm, where, besides teaching botany in one of the State colleges, he was engaged as plant physiologist at the experimental station of the Academy of Agriculture In 1885 he became professor and director of the department of plant physiology of the Academy, a position which subsequently comprised the department of agricultural botany Prof Eriksson held this position until 1913, when he had reached the age limit, entitling him to a pension He, however, continued his research work until shortly before his death, and published several books and monographs during his retirement His primary interest centred on the study of the diseases of agricultural plants, more especially mildew, parasitic fungi, etc It was very largely due to his energy and initiative that the plant physiological laboratory at Frescati, near Stockholm, was created

Prof Eriksson was a member of scientific academies in several countries and received numerous awards for his contributions to the knowledge of plant diseases and their treatment A species of fungus in the Hysteriaceæ group has been named after him, and in 1923 an international prize for

research in plant pathology was instituted at Wageningen in his honour He represented Sweden at nearly all of the international congresses on horticulture and plant physiology, and devoted a large part of his time in the interest of the International Institute of Agriculture in Rome

In addition to the work mentioned above, Prof Eriksson took a keen interest in pomology, and for a number of years edited the *Journal of the Swedish Garden Association*

WE regret to announce the following deaths

Mr W F Denning, a leading authority on meteors, discoverer of several comets, and of world wide reputation as an astronomical observer, on June 9, aged eighty two years

Baron Kitasato, For Mem R S, of the Imperial Pathological Laboratory, Tokyo, Japan, noted for his work in bacteriology, especially with reference to the artificial production of immunity to disease, on June 14, aged seventy-two years

Dr R C Macfie, Thomson Lecturer in the University of Aberdeen for 1929, and author of a number of notable biological expositions, as well as of volumes of picturesque verse, on June 9

Dr Warner J Morse, director of the Agricultural Experiment Station, Orono, Maine, on Mar 25

Prof S W Parr, emeritus professor of practical chemistry in the University of Illinois, known for his researches on fuels, on May 16, aged seventy-four years

Mr H Tomlinson, F R S, formerly principal of the South-Western Polytechnic, Chelsea, on June 12, aged eighty four years

Mr R T Wright, formerly fellow and tutor of Christ's College, Cambridge, and secretary of the University Press, on June 11, aged eighty-five years

News and Views

THE doctrine of the inheritance of acquired characters is by no means so dead as its opponents thought a generation ago The effects of Weismann's knock out blow are wearing off, and the heart begins to throb again, somewhat irregularly, but gaining strength all the time In his Royal Institution Discourse of June 5, on "Habit The Driving Factor in Evolution", printed in a special supplement this week, Prof E W MacBride takes a strong stand on the side of the heritability of acquired characters Dissatisfied with the evidence formerly adduced for the occurrence of evolution, he re examines the question along three lines which he regards as the only possible approaches These are the line of racial differentiation amongst animals at the present day, the line of fossil evidences of past specific changes, and the line of embryonic and larval development And each of these lines, traced to its end, leads Prof MacBride to the conclusion, which would have delighted Lamarck as it will shock many adherents of orthodoxy, that habit or change of habit is at the bottom of the changes of structure which represent the difference between one species and another The interesting examples cited in support of the thesis will be eagerly scanned, but whether all of them will satisfy the doubters is another question

To take the case of the blenny or viviparous eel of the Lym fiord, the individuals of which at the mouth of the fiord are longer and slimmer than their relatives higher up, without direct proof it is unsafe to assume, and the argument is based on the assumption, that the difference is due to different habits May it not be that the differences represent responses to physical differences in the environment, such as varied densities or salinities? Racial differences may be due to habitat as well as to habit, and until the one possibility has been eliminated the other cannot be taken for granted In a similar way it is possible to imagine that the reversion of the spherical race of the nematode, *Heterodera schachtii*, in the potato, to the lemon seed form when it feeds again on beetroot, may be due to physical or chemical properties of the juices it feeds upon—a physical rather than an organic reaction But this sort of objection to regarding habit in every case as the initiator of structural change does not apply to other examples cited by Prof MacBride, and we view with sympathy his championship of the directive force of the organism in the evolutionary race

IN an article on "The Scientist and the Technologist in the Textile Industries", published in the *Journal of Textile Science*, Prof E F Barker discusses co operation between men of science and technologists and problems of their training Prof Barker points out that the technologist, or 'practical man', as he is frequently described in the textile industries, has attained his results much more by judgment and less by rule of thumb or haphazard methods than the man of science frequently imagines Examples are quoted of textile problems faced and evolved along inductive lines of reasoning by the technologist, which indicate that some technologists at least may claim to be scientific workers within the sense of Sir Arthur Eddington's definition of science as "an attempt to set in order the facts of experience" The training of the technologist in the best of our technical colleges has been based largely upon system and not mere synopsis, and upon basic inductive methods The technologist thus chiefly needs the cultural scientific training, based upon the extensive outlook or extensive "Science Discipline" suggested by Sir David Prain The man of science, on the other hand, is essentially an analytical worker, and a fundamental defect of our present university training is that, while taught to appreciate facts, its graduates are frequently quite unable to assess values, especially human values This defect has largely been responsible for the slightly contemptuous attitude towards industrial research once common in university circles, and makes the exclusion of the technologist from association with the man of science in the activities of the research associations catastrophic Probably nothing would more rapidly ensure the provision of adequate support for such associations from the industries themselves than effective co-operation between the scientific worker and the technologist.

PROF BARKER urges that the man of science, having passed through the cultural scientific training, should proceed to the sterner discipline of an intensive training in which studying, as Sir David Prain suggests, "everything of something" evolves scientific, mental, and material tools, and the capacity to use them intensively, by means of which he may draw from Nature more of her riches for the service of mankind The failure of scientific workers to attain greater success than they have hitherto attained is due to lack of appreciation of the problems which only broad co-ordinated enterprise can present for solution The training suggested should assist the scientific worker to clarify or to reveal for the technologist the problems and factors with which he has to work, and if the technologist by taking the extensive "Science Discipline" as part of his course acquires the scientific outlook, the required co operation between science and technology should easily be obtained Such collaboration, and the twin advance of science and technology, are essential if both are to play their part in solving the world problems which they have largely created The cultivation of a sense of values should, moreover, promote co operation with art and humanitarianism—those other aspects of industry which have their part to play in the future as in the past in correcting the soul destroying influences of mechanical work The success or failure of Western civilisation may, as Prof Barker suggests, depend upon the extent to which these aspects of industry function, not merely to serve the material interests of mankind by the secrets won from Nature, but to promote man's higher interests and the spirit of world fellowship

Antiquity, thanks to a vigorous and courageous editorial policy, has attained a position in periodical literature which in Great Britain is unique It has succeeded in maintaining its popular interest without thereby losing its attraction for more serious readers who wish to be kept abreast of the archæological movement in branches of study other than their own Thus, in the June issue, Miss Caton Thompson gives a brief preliminary account of the problems, such as the relation of palæolithic and neolithic culture to water supply, which the first season's work of the Royal Anthropological Institute's expedition to Kharga oasis is revealing for future investigation, while the series of air photographs by Lady Bailey are most valuable as indicating the nature of the terrain In the same way, Mr J Leslie Mitchell's "Inka and Pre Inka" is a useful summary of present theory for those who have not been able themselves to follow recent developments in South American archæology in detail Mr Cyril Fox's study of "Sleds, Carts, and Waggons" in Wales is not only a valuable record of the development and relation of types of vehicles which are now passing out of use, but is at the same time an instance showing how a highly specialised type which has developed in response to local conditions may survive for a considerable time even in the face of the standardisation of modern industry We refer to Dr Reisner's contribution on "Stone Vessels found in Crete and Babylonia" elsewhere, and must pass over other matters of moment in favour of a question raised by the editor in his "Editorial Notes"

IN his "Editorial Notes" the editor of *Antiquity* directs attention to the "astonishing fact that there exists no University Chair of what may be called Old English Archæology", meaning by that expression, the antiquities of the Saxon, Danish, and Norman periods To those who are not acquainted with the circumstances, while this may seem a matter for regret, it may not appear of special urgency There are other subjects of special study, of equal or even greater importance, which are without this provision But, as the editor justly points out, not only have some of the most recent monographs on Anglo Saxon antiquities been written by distinguished Continental archæologists, but also—and this is the more serious aspect of the matter—such knowledge as we have on the period, say, between A D 450 and 650, is concentrated in a few individuals whose numbers do not increase as time goes on, while for the period A D 700 to 1000 accurate scientific knowledge, based on proved fact, is almost entirely lacking Yet there is ample material in Saxon and Danish earthworks, for example, upon which no work of excavation has ever been carried out In view of the lack of encouragement given to these studies, there is a very real danger that research in this by no means uninteresting phase in our history may entirely die out The modern standard of scientific excavation is too exacting to make it advisable to rely on private effort, however successful this may have been in the past in the initial stages of other branches of archæological investigation, while the endowment of a chair would at least give organised direction to investigation, and probably provide the stimulus of open discussion and criticism which is essential to progress in this as in other similar studies

THE Empire Forestry Society has recently published a second issue of a most useful little work entitled, "The Empire Forestry Handbook" The handbook gives a list of office bearers and members of the E F Association, a list of forest officers of the Empire (not without its value, but liable to get quickly out of date), a list of higher forestry educational centres in the Empire, a list of Empire research institutes, a list of departments and institutions dealing with imperial forestry—incomplete, since several universities which, apart from education, certainly deal with imperial forestry are omitted, data and tabular statements purporting to give the forest resources of the Empire, but inevitably, in the case of large areas of our tropical forests in as yet imperfectly known regions, based on the roughest of estimates, and finally a useful list of trade names of Empire timbers which it is hoped gradually to get established

ON the subject of forest research institutes in Great Britain the following comment may be made Under these institutes the Forestry Commission is first mentioned, then the Imperial Forestry Institution, Oxford, and thirdly, the Forest Products Research Laboratory, Princes Risborough This ends the list of centres said to be undertaking forestry research in Great Britain, but

examples of such work being conducted in connexion with Empire forestry interests at other centres could be quoted Perhaps the simplest for reference is furnished by Dr Rayner's letter in connexion with forest research which appeared in NATURE of April 4 The paper alluded to, "Mycorrhiza in Relation to Tree Growth", was actually published in the *Empire Forestry Journal*, vol 9, No 2 1930 As was pointed out in the leading article in NATURE of May 16, on "Forestry Research in Great Britain", if forest research work for the Empire is really to pull its weight, the Forest departments require to harness every centre which is able to undertake such investigation work Dr Rayner has shown that Bedford College for Women, London, is capable of performing such work In the next issues of the Handbook it may be hoped that the editor will be able to find a place amongst his research institutes or centres, since the Forestry Commission, London, cannot be termed an institute, for the Bedford College for Women, and other places in Great Britain equally interested in Empire forestry research

THE radio equipment of recently built luxurious liners is now wonderfully complete The new liner, the *Empress of Britain*, is furnished with both long wave and short wave installations The latter waves enable telephone communication to be maintained over distances which are quite outside the range of the long wave transmitter Hence telegrams can be exchanged directly with the country from which the passenger comes, and this effects considerable economies Emergency and lifeboat radio equipment are also supplied The ordinary cabin telephones are connected with the short wave transmitter, so that the service is as convenient as when on shore London connects each cabin telephone with practically every telephone in Europe, and New York with Canada, the United States, and Mexico The Marconi repeater equipment enables the ship's band to be heard in any part of the ship There are eleven loud speakers for the decks and public rooms and two for private cabins They can be used for making announcements The loud speakers are mounted in the structure of the ship so as to harmonise with the decorations A special type of radio receiver enables broadcast programmes to be heard when they become available Gramophone records relieve the orchestra when necessary, and supply dance tunes Four large cabins are devoted exclusively for the radio apparatus The Marconi direction finder is installed in the chart room for the convenience of the navigating officers The radio equipment was installed by various companies acting on behalf of the Marconi International Marine Communication Co, Ltd

ON the occasion of the recent opening of its central laboratories, the British Non Ferrous Metals Research Association has issued a pamphlet entitled "Ten Years of Research for the Metal Industries", which provides, in a convenient form, an account of the work done by the Association since its formation in 1920 The main features of this work have been described on many occasions, and attention is now particularly directed to the efforts made, largely at the suggestion of the Director, to bridge the gap which undoubtedly exists between the solution of a problem in the laboratory and its general application in industry Even where, as in this case, the interest of the principal firms in the industry has been secured, the time lag which occurs between the issue of a laboratory report and the news that the report has had an actual influence on practice is so great as to disappoint those who have been most eager to promote industrial research The Association has done its best to diminish this time lag, first by an intelligence service which enables its members to keep abreast with work that is being done all over the world, and next by a Development Section, with its own trained staff, the duties of which will increase in importance as time goes on The new aluminium brass condenser tubes, the improved materials for locomotive firebox construction, and the ternary alloys of lead for the sheathing of cables are among the chief practical results of the work of the Association, and each of these calls for special effort in securing their general adoption by members

WHERE there are no civic regulations to the contrary, modern buildings in cities are ever growing taller In Europe, ten and twenty storeyed buildings are getting not unusual, and in the United States there are buildings with fifty storeys In order to let sun light reach the streets underneath, the buildings are made narrower near the top This makes the problem of providing shafts for the requisite lifts very difficult In the *Westinghouse International* for April, an interesting account is given of a method that has been adopted in an eleven storey office building in East Pittsburgh for increasing the transport facilities up and down the building There are two shafts in the building and each shaft has two cars At first sight it seems dangerous to operate two cars in the same shaft and on the same set of rails The difficulty has been overcome by running the cars to a fixed schedule Both complete their trips upwards before either of them starts on the return journey They thus always operate in the same direction The limits for the lower car are the bottom of the shaft and the upper car, and the limits of the upper car are the lower car and the top of the shaft For the dual control, the car is automatically slowed down and stopped before it catches up the other car In addition, a set of signals is displayed within the car, so that the passengers and operator know at once why their car is slowed down or stopped before it reaches its destination The control panel shows at each instant the location of each car and also illuminates three signal lights The green light indicates full speed, the yellow light slow speed, and the red light indicates a stop

CONSIDERABLE attention is being paid at present to the part that wireless will play in the future in the growth of international communication Many believe that it is only a question of time until it will become the universal medium for communication, and that wire and cable systems will become obsolete On the other hand, some believe that the future of wire-

less is very limited, and that it will be mainly confined to broadcasting and communication with and between mobile stations. It is quite possible that wireless will be displaced eventually from the broadcast field for local areas by the use of wire broadcast systems. In a paper published in *Electrical Communication* for April, H. H. Buttner discusses this question fully. He concludes that in the future development of international communication there will be a definite use for both wire and wireless systems. Short wave systems for long-distance communications are generally the more economical. But if the traffic is heavy, or if some is picked up on the main route, it is probable that the cable system would be the best commercially. Owing to atmospheric interference, wireless circuits can rarely give continuity of service over the twenty-four hour day. Cable circuits can also be interrupted by natural causes, possibly over a long period. Wireless can transmit to several stations at once, but the secrecy of cable systems is of great importance in war time. To a large extent, wireless and cable services are complementary to one another. Those services where wireless is essential, such as broadcasting, transoceanic telephony, meteorological and direction finding services, should not be hampered by being allocated too few air channels. The extension of wire and cable communication systems to localities not formerly served owing to economic reasons will release valuable wireless channels for the development and pioneering of new services where the use of wireless is essential.

THE Mineral Resources Department of the Imperial Institute has recently issued a most valuable survey under the title "Mineral Position of the British Empire" (1931, pp. 121, price 2s. 6d.). The mineral production of 1928, as compared with that of 1913, shows that the Empire has fallen back as compared with the world as a whole; but the chief cause of this is the extraordinary increase in petroleum production, to which the Empire contributes only a very small proportion. Otherwise coal and iron ores are the two chief mineral needs of industrial civilisation, and, in these, the Empire has enormous reserves, which should secure for it a high place in the world's industries for some centuries to come. The future outlook as regards supplies of copper and the other base metals, as well as the iron-alloy metals, can also be regarded as promising. Minerals which the rest of the world imports largely from the Empire are asbestos, china clay, chromite, diamonds, gold, mica, nickel, and tin. Minerals for supplies of which the Empire depends almost entirely on foreign countries are antimony, bismuth, borates, petroleum, potash, pyrites, quicksilver, sulphur, and radium. Of all other important minerals, the Empire has ample supplies and great resources, and in many cases an exportable surplus. The position thus disclosed as regards independence in the matter of mineral supplies is one with reference to which the Empire need not fear comparison with the rest of the world. The survey is of great interest and importance, and will prove to be an invaluable mine of information to a wide range of appreciative readers.

IN conformity with the decision of Marshal Lyautey, Commissioner of the International Colonial Exhibition to be held in Paris this year, the Seventh International Congress of Aquiculture and Fisheries is to be included in the programme of the Exhibition. The Congress will be in session from July 20 to 25 inclusive. According to details available in the preliminary syllabus now issued, it will be constituted in three groups, the first dealing with marine fisheries and allied industries, the second with river fisheries, and the third with overseas fisheries. Each of these main groups will be further divided into numerous sections and subsections, each of which will consider and discuss in detail some particular branch or aspect of the general theme. The findings of sections will be communicated to the main groups at combined meetings specially convened. In addition to purely technical work, members of the Congress will join in visits to the Colonial Exhibition and take part in certain of its deliberations. At the end of the meeting, a tour will be arranged to all the principal fishing ports of northern France, including Boulogne, St. Malo, Brest, Belon, and Lorient. Any further information regarding the Congress can be supplied by the General Secretary, 28 Rue Serpente, Paris.

IN a short paper in *Scientia* (vol. 49, p. 335, 1931) Prof. Paola Enriques, of Padua University, endeavours to find a way of conciliation between the apparent contradictions of heredity and evolution. Heredity, to put it broadly, is concerned with the conservation of the species, while evolution, on the other hand, is concerned with the transformation of the species. In the old days, observation of the relationships between parents and children left open a way for evolution, since children, however much they resembled their parents, in some characters were different. But genetics suggests that all the hereditary patrimony of the child can be decomposed into definite and known elements, so that no room is left for the evolutionary novelty. Enriques emphasises the significance of the fact, well known to systematists, that there is amongst related species or groups of species a combination of characters associated with the characters betraying affinity. Further, one set of characters may vary independently of the other. Experimental heredity shows also the possibility of variations in hereditary factors, so that there may be deduced a common law ruling both heredity and evolution, the law of 'independent variability"—"hereditary factors may vary independently of one another, and it is from the independent variations that the formation of new species is derived." So enters the possibility of evolution.

FUNGI form excellent objects of study for the amateur naturalist armed with the microscope, and the March issue of the *Journal* of the Quekett Microscopical Club contains two interesting papers in which different aspects of fungus study are discussed especially for the microscopist. The president of the Club, Mr. J. Ramsbottom, of the Natural History Museum, discusses some of the more interesting of the aquatic fungi, including in his account brief descriptions of

some little known groups in which the English forms, in particular, would well repay intensive study Mr B F Barnes, of the Department of Botany of Birkbeck College, London, discusses quite a different phenomenon By modern technique, using sterile solid media, fungi can be grown in pure culture for years and, thus cultivated, remain as constant in form and in the structure of their reproductive bodies as more highly organised plants It has thus been possible to recognise the fact that variable forms, which sometimes remain distinct in culture whilst in other cases they revert with time to the normal, may be produced from the stable normal types by special treatment Mr Barnes describes the variations he has induced in three different species by heating the spores from which sub cultures are afterwards made

During the last ten years great improvements have been made in photoelectric cells and in valve amplifiers In a lecture to the Royal Society of Arts on Feb 25, W G W Mitchell showed how these improvements have been of the greatest value in the development of television Comparing this art with that of picture telegraphy, where the tones of a photographic print are transmitted over a wire or wireless circuit and reconverted at the receiver end into a permanent record, he pointed out that with television, eighteen complete pictures must be sent out per second, and that the actual speed of transmission must be a hundred times quicker than in picture telegraphy The discovery by Baird that infra red rays could be used instead of the light from a powerful arc lamp made the process of being televised quite comfortable to the subjects The method of two way television over the telephone developed by the American Telephone and Telegraph Company was successful It is very expensive to install, and it has the great drawback of using up some fifteen ordinary telephone conversation channels A two-way 'conversation' by this method was successfully carried out in New York over a distance of two miles between two deaf mutes The conversation was maintained solely by reading lip movements The main difficulty that lies in the way of developing purely electrical methods such as the cathode ray method is the high voltage at present required for operating the necessary tubes The next big development will probably be the production of a picture of the size and brilliancy of the cinema screen picture of to-day This will probably be done by using zone methods of scanning in conjunction with wired transmitting circuits Television should prove a better aid to salesmanship than picture telegraphy It has already been found useful in connexion with researches on the Kennelly Heaviside layer Mr Mitchell expressed the hope that litigation on patents will not hold up the development of television as it did radio communication

The April issue of the *Scientific American* has a short description, with diagrams, of a sonic altimeter produced by the General Electric Company which has been used successfully by the Army Air Corps of the United States A high frequency whistle mounted in a megaphone pointing downwards sends out short blasts at regular intervals, the power being derived from a gas supply tank fed from one of the engine cylinders At each blast a pointer begins to travel round the dial of the altimeter and the pilot reads the position at the instant he hears the echo of the blast by reflection at the surface of the ground He is provided with a stethoscope connected to a second megaphone pointing downwards, mounted in the tail of the aeroplane An acoustic filter in the connecting tube reduces the engine and other aeroplane noises, and it is found that altitudes so low as 50 ft and so high as 1000 ft can be accurately measured even in the densest fog

Typhus fever in the Old World is transmitted by the body louse Recent *Daily Science News Bulletins* of Science Service, Washington, D C, report that Drs Dyer and Badger, of the U S Public Health Service, investigating typhus fever in Baltimore, have obtained evidence incriminating a rat flea as the agent transmitting this form of typhus fever, which may be a type slightly different from European typhus fever It is probable that there are several typhus like fevers, for there are forms of typhus fever in the East which are transmitted by ticks It is of interest to recall that Prof Matthew Hay, of Aberdeen, in 1907, before the mode of transmission of typhus fever was known, suggested on epidemiological evidence that the flea might be the agent

Messrs Bellingham and Stanley have recently issued a new illustrated catalogue of their spectrometric apparatus The general feature in the design of their instruments is the increasing departure, which is now fairly general, from the old conventional type based upon the rotating telescope and collimator Even where the Littrow principle of mounting is not applied, the instruments tend to be made in more compact and mechanically sounder forms, and, occasionally, to be constructed with interchangeable optical systems One spectrometer of rather special interest which has been built specially for the study of the Raman effect, but would be of use in the investigation of any feeble visible source when high dispersion was not required, is a large aperture instrument of aperture $F/2$, with a single prism and a lens of 16 cm focal length, the spectrum between 8000 A and 3400 A occupies a length of 16 mm Among other instruments listed is a polarising photometer for use in the visible and ultra violet regions

The New Physics Building of the National Physical Laboratory will be opened on June 23 at 2 15, by Sir F Gowland Hopkins, president of the Royal Society, and chairman of the general board of the Laboratory Other speakers will be Sir Richard Glazebrook, chairman of the executive committee, who will give a short account of the history of the building, and Sir J J Thomson, chairman of the research committee of the Laboratory At 3 o'clock the president of the Royal Society will proceed to the Main Aerodynamics building, to receive other visitors to the Laboratory

The Bakerian Lecture of the Royal Society will be delivered at 4 30 on Thursday, June 25, by Prof S

Chapman The subject will be "Some Phenomena of the Upper Atmosphere"

THE latest addition to the series of catalogues of Francis Edwards, Ltd, 83 High Street, Marylebone, W 1, is No 538, devoted mainly to "Voyages and Travels before 1750"

THE author of the article on "The Nature and Origin of Ultra Penetrating Rays" in NATURE for June 6, p. 859, writes that the following errors (present in his MS) were overlooked by him in the proof "At the end of the first paragraph '3 7 10^9 e volts' should read '1 9 10^9 e-volts' This error is repeated fourteen lines later Again, the same error appears in that at the bottom of the first column on p 860, 'At present this limit is about 4 10^9 e-volts' should read 'At present this limit is about 2 10^9 e volts'"

APPLICATIONS are invited for the following appointments, on or before the dates mentioned —A laboratory assistant for the medical unit laboratories of the Welsh National School of Medicine—D Brynmor Anthony, University Registry, Cathays Park, Cardiff (June 22) Two munitions committee research fellows at the University of Liverpool (Faculty of Engineering) —The Registrar, University, Liverpool (June 22) A lecturer in mathematics (with physics as subsidiary subject) at the Handsworth Technical College—The Principal, Technical College, Handsworth, Birmingham (June 23) A head of the Evening Building Department of the School for Building, Ferndale Road, S W 4, and a full time instructor of plumbing for day and evening classes at the same institute—The Education Officer (T 1), County Hall, S E 1 (June 24) An assistant lecturer in commerce at University College, Leicester —The Registrar, University College, Leicester (June 27) Two visiting teachers for chemistry and physics at the Norwood Technical Institute—The Education Officer (T 1), County Hall, S E 1 (June 27) An assistant lecturer in the Department of Political Economy of University College, London—The Secretary, University College, Gower Street, W C 1 (June 30) A demonstrator of physics at Guy's Hospital Medical School—The Dean, Guy's Hospital Medical School, London Bridge, S E 1 (June 30) A lecturer in physics in the Egyptian University, Cairo—The Dean of the Faculty of Science, c/o Egyptian Education Office, 39 Victoria Street, S W 1 (July 1) Seven chemical assistants in the Public Health Department of the London County Council—The Clerk of the L C C County Hall, S E 1 (July 6) A tutor of women students in the University of Leeds—The Registrar, University, Leeds (July 6) A half time assistant lecturer in botany at the University College of Swansea—The Registrar, University College, Singleton Park, Swansea (July 7) A demonstrator in physics in the University of Leeds—The Registrar, University, Leeds (July 13) A reader in organic chemistry in the Aligarh Muslim University (candidates restricted to Indian born subjects of the King) —Prof R F Hunter, Box 114, c/o NATURE Office A lecturer in charge of the Building Department of the Norwich Technical College - The Principal, Technical College, Norwich

Our Astronomical Column

Calendar Reform —A note in this column on June 6 referred to the widespread opposition to any break in the continuity of the seven day week An article by Mr L C W Bonacina in the *Evening Standard* of May 29 goes too far, however, in the opposite direction in resisting all reforms One of his main points is the sentimental association of certain old traditions with the present months But it may be pointed out that many of these associations have already been broken by the change of style Before the change the hawthorn flowered early in May, now it seldom does so till after the middle of the month Again, the old rhymes

Barnaby bright, the longest day and the shortest night
Lucy light, the shortest day and the longest night,

are no longer true The dates of the feasts are June 11 and Dec 13 The strongest argument for a change is, however, the utterly illogical arrangement of the length of the months Since the average length of a month is almost 30½ days, it is clear that all months should have either 30 or 31 days. The abnormal shortness of February is due to the pride of some Roman emperors, who wished their months to have 31 days It is strange that mankind has tolerated the anomaly for nearly two thousand years

Different methods of improvement are possible The simplest is to make the lengths 30, 31, 30, 31, etc, with the final 31 changed to 30, except in leap year Another arrangement is 31, 30, 30, 31, 30, 30, etc, with an additional 31 at the end, this has the advantage that the first three quarters are each exactly 13 weeks. The leap day should be placed at the end of the year, so that it does not alter the interval from one calendar date to another in the same year

It is clear that there is room for improvements, and the prospects of carrying them out are rendered brighter if they are not too drastic It would be wise to drop all tampering with the week, such a change excites strong opposition

A Very Massive Double Star —A *Daily Science News Bulletin*, dated Washington, May 20, reports that another very massive double star has had its mass determined, by Dr J A Pierce, at the Dominion Observatory, Victoria, B C It will be remembered that the greatest star mass hitherto measured was that of the spectroscopic binary in Monoceros known as the 'Plaskett Star', since it was detected by Dr J S Plaskett, director of the Observatory at Victoria That consists of two stars of nearly equal mass, each at least 80 times as massive as the sun, since eclipses do not occur in that star, the exact masses cannot be given, but must be somewhat greater than the above Curiously, the bulletin omits to give the name or position of the newly measured binary, which is one of the most important items in an announcement of this kind, it is stated that its binary character was detected at Mt Wilson between 1920 and 1924, but it has been the subject of more exhaustive study with the 72 inch reflector at Victoria, since the report mentions "spectroscopic and other photographs", and also gives exact values for the masses (not merely minimum values), it may be concluded that eclipses have been detected The period of revolution is 56 days, and the masses of the components are respectively 134 and 50 times that of the sun The centre of gravity is receding from the sun at the rate of 8 km /sec

Research Items.

Chronology and Archæology.—In *Antiquity* for June, Dr. G. A. Reisner examines the method of dating by means of objects from Egypt with special reference to stone vessels found in Crete and Mesopotamia, and incidentally lays down certain principles for its employment. (1) Conclusions have often been reached on the dating of single objects found in Egypt and little attention has been paid to its range. It is, therefore, necessary to know the whole range of time during which the object occurs in Egypt and the variations in form which it assumes in that time. (2) An Egyptian object found abroad must be identical in form, material, and technique with a type of known range in Egypt. It must be remembered also that most objects in Egypt pass through two stages of development, an earlier stage of practical use and a second in which more or less degenerate examples are made for burial purposes only. Taking the history of stone vessels in Egypt, it would appear that the period during which we might expect an export is that from the time of Zer (third king of Dynasty I.) to the end of Dynasty III., but the export as gifts, especially royal gifts, might have taken place down to the end of Dynasty V. or even VI. Examining the evidence from the royal site at Knossos, it would appear that there is no object which can be dated with safety to the predynastic period or even Dynasties I.-II. Sir Arthur Evans's correlation of Early Minoan III., Middle and Late Minoan, with the Egyptian periods is correct in all essentials, but some modification is required for the correlation of the Cretan Neolithic and Early Minoan I. and II., as the history of Egyptian stone vessels has progressed considerably since the studies upon which he relied. Taking the material from Ur, so far as published, while the technique has some similarity to the most usual form of Egyptian technique—the boring with a stone—none of the vessels reported from Ur is of Egyptian origin, and they serve no useful purpose in the correlation of the early Sumerian and Egyptian periods.

The Development of the Thyroid.—Ernst Marcus (*Die Naturwiss.*, 27, Feb. 1931) gives a brief account of the development of the thyroid glands in Amphibia, based on his two recent papers on this subject in *Zool. Jahrb.* (Anat. Ontog. 52, Allg. Zool. u. Physiol. 49). Investigation of the ingrowing nervous layer of the ectoderm in all three orders of Amphibia—Gymnophiona, Urodela, and Anura—shows that the thyroid arises from this layer without participation of the endoderm. Implantation of oral ectoderm and mesoderm in the ventral region of the young larva results in the development there of thyroid; the turning of the presumptive oral ectoderm through 180° results in the development of a thyroid lying dorsal to the gut. If a piece of ectoderm the dorsal margin of which borders the ventral half of the presumptive oral region be turned, the portion of the nervous layer which remains in its natural position gives rise to a normal thyroid directed obliquely ventrally away from the endoderm of the gut, while the other portion of the nervous layer produces a thyroid directed obliquely dorsally and without relation to the endoderm.

Axolotls in Captivity.—Number 8, volume 4, of the *Aquarist and Pond Keeper* (May-June 1931) includes several references to the axolotl. In "Notes from the Brighton Aquarium", Mr. George W. Weller describes both black and white varieties. In the "Readers' Records", Mr. John Gray notes that an axolotl had tried to eat a stickleback, which choked and killed it; and Mr. W. E. Teschemaker makes the very interesting statement that a pair of axolotls living in an out-of-door pond have spawned and that the eggs are on the point of hatching. The parents have found their own food since last May, when they were first placed in the pond. The same observer has already reared the young axolotls in the open from the age of about six weeks or less, so that it is quite possible for the whole of the breeding and rearing to take place out of doors at low temperatures.

The Great Crossbill Movement of 1927.—In the summer and autumn of 1927, as many records in the British Isles witnessed, there occurred an important migration of crossbills (*Loxia curvirostra*). The movement, summarised by Ad. S. Jensen, extended over the greater part of Europe from mid-Russia to western France, Ireland, and Iceland, from Finmark to mid-Italy and the Ukraine, and even to the southern parts of western Siberia (*Det Kgl. Danske Vidensk. Selsk., Biol. Meddel.*, 10, 1, 1930). It was noticeable that the crossbills showed themselves earliest in the most easterly countries visited and progressively moved westwards. The origin of the flight, therefore, must be sought in the east, indeed in the northern parts of Russia and Siberia, where the great pine forests form the particular habitat of these birds. When explaining the migration, it must be remembered that in the summer of 1927 the pine-trees in these parts made extremely poor growth and the pine seed harvest was a failure, so that the crossbills, deprived of their staple food, were compelled to wander to fresh feeding-grounds.

Biological Control in Mauritius.—Mauritius, like many other sugar cane growing countries of the world, suffers severely from the ravages of Lamellicorn beetle larvæ. The species *Phytalus smithi* appears to have been accidentally imported into Mauritius from Barbados, some time prior to 1911, when it was first recorded as a pest. Good work has been achieved by various artificial methods of control, and this has been augmented by the application of biological measures. In 1916, the solitary wasp, *Tiphia parallela*, was introduced from Barbados and has now become well distributed over the whole region of infested cane. The present day position of the problem is described by Mr. D. d'Emmerez de Charmoy, in the issue of the *Bulletin of Entomological Research* for March. He points out that since the *Phytalus* has been well established in Mauritius, some twelve or fifteen years before the introduction of its parasite the latter is, for the time being, at a disadvantage from the economic point of view. Years must elapse before it can increase to the point where it will exterminate a sufficient proportion of the host population to yield the desired degree of control. At present the *Tiphia* destroys up to 30 per cent of the *Phytalus* and its work is being augmented by a second parasite, *Elis thoracica*, which was imported from Madagascar in 1917. At the present juncture, it may be said that artificial measures of control are required to be rigidly prosecuted so long as the biological method remains only very partially efficacious.

Tea in India.—Dr. Harold H. Mann's lecture, published in the *Journal of the Royal Society of Arts* of April 3, upon the scientific aspects of the Indian tea industry, was an interesting historical résumé, by one qualified to speak, of the progress in tea cultivation under Indian conditions. Dr. Mann went to India in

1900 as the first scientific officer of the Indian Tea Association When tea plants were first cultivated in India, early in the nineteenth century, plants were introduced from China, but the discovery of indigenous tea plants on the borders of India and in Assam directed attention to the suitability of certain districts, especially Assam, for tea cultivation, and in 1839 the Assam Company was floated to take over and extend two-thirds of the Government plantations in the province In those days, only Chinese experience and Chinese methods of cultivation were available, and Dr Mann suggests that the Indian industry has only thrived since it has been broken away from these methods and developed its own Tea is a crop with special requirements, it thrives on acid soils and deteriorates upon liming, the crop required is not flower or fruit, but the young leaf, so that a special pruning and cropping technique is required in order to encourage the continual succession of young leafy shoots suitable for plucking

Flora of Lancetilla Valley, Honduras —In compiling an enumeration of lowland Honduran plants of the region about Lancetilla Valley and the port of Tela, P C Standley (Field Museum of Natural History, *Botanical Series*, vol 10, Publication 283, Jan 1931) has made available a botanical work which will be equally useful for study purposes anywhere in the lowlands of Central America, as the area is typical of the wet lowlands of the whole Atlantic coast of that country Almost all the area which is not devoted to the cultivation of bananas, which is the principal industry and furnishes the chief article of export from Honduras, is covered by dense forests, wooded swamps, or marshes A general botanical description of the different types of vegetation, with accounts of the climate, geography and inhabitants, economic plants of the district, the relationships of the flora, vernacular names, and previous botanical exploration of the region, precede the descriptive flora Both flowering plants and cryptogams are included, though the list of the latter is very incomplete Many of the commoner plants are well illustrated

Permian Insects —In part 13 of his series of papers on "Kansas Permian Insects", Dr R J Tillyard (*Amer Jour Sci*, 21, p 232, 1931) deals with a small group which at first sight appear to be true Coleoptera (or beetles), but a study of the venation and method of folding of the hind wing shows that there is no close relationship between these two groups For these Permian insects Dr Tillyard proposes a new order, the Protelytroptera, which he regards as the ancestral group from which the existing Dermaptera (or earwigs) have been derived

Fossils of the Upper Rhine Valley —W Salomon-Calvi ("Oberrheinischer Fossilkatalog," Lief 1, Berlin Gebrüder Borntraeger, 1931, 35 gold marks) has edited a catalogue of the fossils found in the upper Rhine valley extending from Basel in the south to Hunsrück and the Taunus in the north Under each species references are given to the works in which it is recorded or described, to the locality and horizon, and to the museum in which specimens may be seen The part now published is divided into five sections 1, "Palæozoic Animals" by M Pfannenstiel, 2, "Triassic Vertebrates" by W Scheffen, 3, "Jurassic Invertebrates" by W Deecke, 4, "Triassic and Jurassic Vertebrates" by M Pfannenstiel, 5, 'Palæozoic and Mesozoic Plants" by K Frentzen.

Ionic Wind Voltmeter —One of the earliest effects noticed when a pointed conductor was connected with a source of high voltage was the electric wind produced at the point The wind is produced by the ions colliding with the uncharged molecules and giving them velocities The effect is observed at both the high tension and the earthed pole When the latter is enclosed in an insulating vessel and a bent wire is used as an electrode, it is found that the wire is cooled by the alternating component of the wind according to definite laws This phenomenon is used in the ionic wind voltmeter described by Prof W M Thornton, W Waters, and W G Thompson in the *Journal of the Institution of Electrical Engineers* for April By making the earthed electrode part of a hot wire, bridge readings are obtained from which the voltages can be determined The readings are due to the applied field upsetting the balance of the bridge Indoor forms of voltmeters are made to indicate up to 300 kilovolts, and outdoor forms up to 132 kilovolts In addition, portable forms from 3 to 150 kilovolts are made for general testing and X-ray work The authors describe also a thermo-electrostatic relay which should prove a help in maintaining uniformity of voltage on the grid, a problem of considerable importance in distribution If a fault or an excess load causes the line voltage to vary, the device actuates a warning signal The authors state that the researches they made during their investigation on electrical discharge of gases have disclosed a new method of comparing molecular ionising potentials

Fibre Structure —An illustrated pamphlet of eighteen pages, issued by the University of Leeds, gives an account of the research work done there during the session 1929-30 with the aid of a grant from the Cloth workers' Company It includes a five page summary of the advances in our knowledge of the atomic structure of fibres by the X-ray analysis work of Messrs W T Astbury and H J Woods Wool in its natural state is built up of a number of molecular chains folded into a series of hexagons, and when the wool is stretched these hexagons break up into long zigzag lines the length of which may be double that of the series of hexagons On the withdrawal of the stretching force, the original hexagonal form is resumed Natural silk, on the other hand, behaves as would wool already stretched, and has not the long range elastic properties of natural wool While steam has little effect on the properties of natural wool, it deprives stretched wool of its elasticity, and when the stretching force is removed the wool remains set in the extended state This fact has important bearings on the dyeing and conditioning of wool and on other textile processes The Government Grant Committee of the Royal Society granted £200 last year for the furtherance of these researches

Rotation of Molecules in Crystals —It has been suggested that in many cases there may be complete rotation of the molecules in crystals at temperatures below the melting point, and the transitions involving considerable absorptions of heat which have been found for solid hydrogen halides may be explained as due to the taking up of rotational energy by the molecules The transition of solid hydrogen chloride is perfectly isothermal at 98 36° abs and requires 284 3 cal per mol This explanation would require that the solids should have high dielectric constants, and for hydrogen chloride, for example, the dielectric constant of the solid should increase considerably at 98 36° abs Cone, Denison, and Kemp, in the April number of the *Journal of the American Chemical Society*, show that this is the case A temperature range of 85° to 165° abs was used At 98 4° abs the dielectric constant changes isothermally from 3 to 10 Thus the theory of the rotation of the molecules in the crystal is supported

The Ross Institute and Hospital for Tropical Diseases

THE twenty fifth anniversary in 1923 of Sir Ronald Ross's epoch making discovery of the transmission of human malaria through the bite of anopheline mosquitoes was the occasion of an appeal for the foundation of an institute for research upon, and for the treatment of, tropical diseases which should serve as a lasting monument to Ross's achievement

As a result of this appeal, initiated by Sir William Simpson and Sir Aldo Castellani and supported by many influential signatories in all parts of the world, funds were contributed by Indian princes, colonial governments and municipalities, city companies, rubber, tea, oil, and other trading companies, and private individuals a house and grounds were acquired on Putney Heath, London, and the building was adapted partly as a hospital for the treatment of patients suffering from tropical diseases and partly as laboratories for research This constitutes the present Ross Institute and Hospital for Tropical Diseases, of which Her Grace the Duchess of Portland is president

The Institute is administered by a council of which Sir Charles Campbell McLeod is chairman and Major Lockwood Stevens, secretary The staff includes Sir Ronald Ross himself as director in chief, Sir William Simpson, director of tropical hygiene, and Sir Aldo Castellani, medical director, with Sir Malcolm Watson in charge of the Malaria Department The annual Report for 1930, recently issued, surveys at some length the activities and research work of the Institute An increased number of patients were treated in the hospital during the year, the total number being 85

Sir Ronald Ross has continued to write upon malaria and its control, Sir William Simpson is investigating the longevity of the plague and other bacteria, and Sir Aldo Castellani has published several papers on minor and other ailments of the tropics and upon fungi which attack the skin Dr Shaw Mackenzie is continuing his studies of the blood changes that occur in cancer and on the diagnosis by blood tests and treatment of this disease In the malaria laboratory, observations have been made on the influence of cold upon the larvæ of the British tree breeding anopheline, *A plumbeus*, showing that they hibernate and resist even freezing in the water in the tree-holes A lengthy survey is given of the activities of the Anti Malaria Advisory Committee of the Institute in the control of mosquitoes and malaria abroad, this work was referred to in NATURE of Jan 31 p 173

Courses of instruction have been given to planters and others interested in the control of malaria Unfortunately, the income for the year shows a decrease of £1500, partially counterbalanced by a reduction in expenditure of £628 on 1929 The financial position of the Ross Institute is unsatisfactory, as at present the Institute is entirely dependent upon voluntary contributions, and an appeal is made for funds to create an endowment fund

In a series of appendices, the malaria policy of the Ross Institute is outlined and the results of malaria preventive measures summarised Mr Jackson Clarke, a veteran worker in cancer research, is arranging his collection of slides and photographs for exhibition in the laboratories

Bi-Centenary of the Foundation of the Royal Dublin Society

THE bi centenary of the Royal Dublin Society will be celebrated in Dublin on June 23–26 The history of the Society is in many respects remarkable As regards the scope of its activities it is probably unique The first meeting of the Society was held on June 25, 1731, in the rooms of the Philosophical Society in Trinity College, Dublin The earliest definition of its objects is expressed as follows

"It was proposed and unanimously agreed unto, to form a Society, by the name of the Dublin Society, for improving Husbandry, Manufactures and other useful arts"

A few days later, on July 1 at the second meeting, it was agreed that the words "and sciences" should be added after "arts" in the title of the Society

Among its earliest members the name of Thomas Prior appears He had graduated in Trinity College, Dublin, in 1703 He acted as secretary of the young Society for twenty years, and is by many regarded as its founder Several distinguished names appear as early members among others, that of Dr John Madden, whose son, Samuel Madden, D D, became a member in 1733 and proved to be one of its most loyal, able, and generous supporters He became known as 'Premium Madden' because of his wise policy of offering premiums for methods of tillage, etc He was influential in obtaining for the young Society its first charter

Among the earliest members many other noteworthy names appear, including that of Sir Thomas Molyneux, a fellow of the Royal Society, who was a friend of Robert Boyle, of Sir William Petty, of Newton, Evelyn, Dryden, and Locke Molyneux's scientific interests were wide, he first gave a rational account of the origin of the Giants' Causeway, and wrote a scientific report on the Irish elk In general, however, matters of a practical character engaged the attention of the young Society such as Prior's paper on 'A New Method of Draining Marshy and Boggy Lands"

The foundation of local branch societies in the principal towns and cities of Ireland, which should establish communication with the Dublin Society, was promoted There is no doubt as to the practical and directly beneficent character of the work of the young Society, and, at the same time, of its interest in the promotion of applied and general science

This was in the days of that brilliant but unhappy genius, Jonathan Swift A very extraordinary anonymous book, printed in Dublin in 1753, and written "By a Friend to the Peace and Prosperity of Ireland", is in the possession of the present writer It purports to be "A Dialogue between Dean Swift and Thos Prior, Esq, in the Isles of St Patrick's Church, Dublin, Oct 9, 1753" The shades of the two defunct speakers, rising at midnight from the grave, discuss the economic conditions of Ireland and how best they can be improved The constructive ambitions of Prior are in general exposed to the caustic satire and pessimism of the Dean But in the end both agree on the necessity of reforms The dialogue, covering 134 pages, is brilliant throughout

In the first century of the Society's existence, systematic works, not only of economic and practical nature, but also in many cases of considerable scientific interest, were published by the Society The now well known 'Spring Shows' of the Society were inaugurated in 1831, and the stated meetings of the scientific members of the Society began some three years later

It has been said that most of the good which has been done for Ireland has been done by this great

institution To its initiative and labours Dublin owes its beautiful Botanic Gardens at Glasnevin, its Museum of Art and Natural Science, its National Gallery and School of Art, its National Library, and its College of Science now amalgamated with the National University The Irish Fishery Department is largely due to its initiative and early support Its great agricultural shows and horse shows are known over the world

More recently, the Irish Radium Institute came into existence as one branch of the Society's beneficent work Its fine pioneer work in advancing radio therapy, mainly due to the late Dr Walter Stevenson, is widely known The functions of this Institute extend to all parts of Ireland

The support of science, pure and applied, in all its branches has been one of the Society's principal functions in recent years Its *Transactions* and *Proceedings* include some of the most important writings of Fitzgerald, Stoney, Preston, Trouton among others The Society supports a liberal fund for the prosecution of research by the purchase of scientific instruments which are supplied on loan to the investigator, or by money grants when a hopeful investigation is involved In its great hall, seating 1600 persons, scientific lectures suited to a youthful audience or, again, to an audience of adults are delivered annually by recognised scientific authorities Still more advanced lectures and demonstrations are delivered periodically in a smaller apartment

From remote times the Society has promoted the fine arts, as already mentioned, and offers to young artists annually a valuable prize upon the result of competitive work The prize is of sufficient value to enable the winner to go abroad for the study of art, if he so desires Nor has the cultivation of music been neglected Throughout each session eminent musicians perform for the benefit of the members and of the general public

The membership of the Society to-day numbers 9000, and a long waiting list exists The great educational value of its membership is recognised by all

In the celebration of its two hundredth birthday, every effort will be made to recall its earlier history, as well as to show by contrast the advance between then and now Early scientific instruments of historic value will be shown Recent instruments for research devised by members of the Society will be on view Works of art from Irish painters or sculptors which have arisen out of the Art School long ago established by the Society will be brought together A period ball on June 26 will close the celebrations In this, efforts to reproduce the costumes of the past will be encouraged

June 23 is the opening day A conversazione, and reception by the president, will be held on the evening of that day

The North Sea Earthquake.

LATER reports on the North Sea earthquake of June 7 add little, if anything, to our knowledge of its distribution Several of the cracks in the Chapter House of Lincoln Cathedral were found to be widened, and the shock was felt so far to the south as Paris The former city lies within the area of slight damage as previously traced, the latter within the boundary of the disturbed area The course of that boundary towards the east and north remains uncertain, in the absence of records from western Germany and Denmark

An unusual feature of the earthquake is the great extent of the sound area In Great Britain, the sound was heard at several places not more than fifty miles within the boundary of the disturbed area The double nature of the shock was also observed over a wide area, and even at places so near the boundary as Elgin and Bristol

It is remarkable that some of the earthquakes most widely felt in Britain should be of submarine origin The earthquake of 1852—the only one felt in all four divisions of the British Isles—disturbed an area of not less than 56,000 sq miles The exact position of the epicentre is unknown, but it was probably submarine and not far from the coast of Ireland The shock so generally felt in eastern Scotland four years ago was connected with a centre to the west of the Norwegian coast A centre lying a few miles east of Jersey has been responsible for several shocks felt over the south of England and even in London The disturbed areas of the Jersey earthquakes of 1878 and 1889 contained about 68,000 sq miles, while that of the earthquake of 1926 cannot have been much less

So far as we know the focus of the recent North Sea earthquake has not been in action for several centuries The injury to the Chapter House at Lincoln suggests, however, that a strong earthquake in the year 1185 may have been connected with the same centre The shock is briefly described in several monastic and other chronicles According to Holinshed ("Chronicles", vol 2, pp 188 189), "On the mondaie in the weeke before Easter, chanced a sore earthquake through all the parts of this land, such a one as the like had not beene heard of in England sithens the beginning of the world For stones that laie couched fast in the earth, were remooued out of their places, stone houses were overthrowne, and the great church of Lincolne was rent from the top downwards"

C DAVISON

University and Educational Intelligence

CAMBRIDGE—Dr S Goldstein, of St John's College, and Mr J M Whittaker, of Pembroke College, have been appointed University lecturers in the Faculty of Mathematics

Dr N J J M Needham, of Gonville and Caius College, has been reappointed University demonstrator in biochemistry

The Appointments Committee of the Faculty of Biology 'B' invite candidates for the post of University demonstrator in experimental psychology to send in their names to Prof Bartlett (at the Psychological Laboratory), together with such evidence of their qualifications as they think fit, not later than Oct 1, 1931 An appointment will be made early in the Michaelmas Term 1931 The salary of the demonstrator will be £160 per annum

The Benn W Levy research studentship in biochemistry is vacant Applications for its tenure should be addressed to Sir F G Hopkins at the School of Biochemistry, before July 1

The title of Professor Emeritus has been conferred on Sir R H Biffen upon his retirement from the professorship of agricultural botany

The General Board has been authorised to re-appoint Sir Horace Lamb, of Trinity College, to the Rayleigh lectureship in mathematics

The Vice Chancellor, Prof Seward, Master of Downing College, T Knox Shaw, of Sidney Sussex, Prof Debenham, C F Cooper, of Trinity Hall, Sir E H Young, of Trinity College, J M Wordie, of St John's College, and R E Priestley, of Clare College, have been appointed a Syndicate to prepare a scheme for the erection of a building for the Scott Polar Research Institute

Prof G H Hardy, Savilian professor of geometry

in the University of Oxford, has been elected to the Sadleirian professorship of pure mathematics, in succession to Prof E W Hobson, who has resigned

---

Applications are invited by the Director of Agriculture, Punjab, for the Maynard Ganga Ram Prize of the value of 3000 rupees, which will be awarded for a discovery, or an invention, or a new practical method tending to increase agricultural production in the Punjab on a paying basis Applications must reach the Director of Agriculture, Punjab, Lahore, by, at latest, Dec 31, 1932

The Council of the Institution of Electrical Engineers offers a Ferranti Scholarship of the annual value of £250 and tenable for two years, for whole time research or post graduate work Candidates must be less than twenty six years of age, and nominations must be received by Aug 15 Particulars of these scholarships can be obtained from the Secretary of the Institution, Savoy Place, London, W C 2

The following have been appointed to Commonwealth Fund fellowships tenable by candidates from the British Dominions Mr Ernest Beaglehole (New Zealand and London) to Yale University, in psychology, Mr N S Grace (Saskatchewan and London) to the University of California, in chemistry, Mr Bernard Notcutt (Stellenbosch and Oxford) to the University of California, in philosophy The following have been appointed to fellowships tenable by candidates holding appointments in Government service overseas Mr T G G Beck (Public Works Department, Government of New Zealand) to the University of California, in civil engineering, Mr B J Dippenaar (Department of Agriculture, Union of South Africa) to the University of Wisconsin, in agriculture, Mr A R B Edgecombe (Public Works Department, Government of India) to the University of California, in electrical engineering, Mr H R Knowles (Department of Agriculture, Union of South Africa) to the University of Wisconsin, in agriculture, Mr E H Samuel (Civil Service, Government of Palestine) to Columbia University, in economics, Mr George Stark (Native Development Department, Government of Southern Rhodesia) to the University of North Carolina, in education

In the Report for the year 1929–30 of the University of Leeds, prominence is given to the development, actual and prospective, of the University's residential accommodation for students Devonshire Hall, begun in 1928, already accommodates 140 men and is one of the largest hostels in a modern university The plans of the building make provision for further expansion, but the extent to which this shall take place will depend not only on funds becoming available but also on the solution of the problem of how many students can appropriately be associated within a single hostel Another important addition to the University's buildings is the mining block, finished during the summer Here accommodation is reserved for members of the scientific staff of the Department of Scientific and Industrial Research engaged on a chemical and physical survey of the coal resources of West Yorkshire, which is part of a survey of the coal resources of Great Britain being carried out by the Government Statistical tables annexed to the report show a substantial increase in the number of day students, both full time (from 1385 to 1434) and part-time (from 144 to 219) Evening classes, chiefly textile and fuel (industrial) show a falling off from 223 to 144

Birthdays and Research Centres.

June 20, 1861.—Prof Sir F G Hopkins, Pres R S, Sir William Dunn professor of biochemistry in the University of Cambridge.

My department is engaged upon a variety of biochemical problems, but of late years we have given the most attention to a study of the catalytic control of biochemical reactions and especially of oxidations in the living cell We are endeavouring to apply such studies widely in the biological field, not to mammalian tissues alone, but to every form of living cell I think that very significant knowledge can be won by studying the metabolism of living organisms, not a little has come to light as the result of work by my colleagues in Cambridge

I have myself returned lately to a study of the functions of glutathione in tissue respiration, and find that, in some tissues at any rate, it plays a real part in the organisation of events I am also following up certain lines of vitamin research

June 22, 1864—Sir Daniel Hall, K C B, F R S, Chief Scientific Adviser, Ministry of Agriculture and Fisheries, and Director of John Innes Horticultural Institution

So far as my personal work is concerned, I am endeavouring to clear up certain points in the taxonomy of tulip species, which has taken on a new aspect since the discovery of polyploidy in the genus by the late Mr W C F Newton Tulips present various other problems of great significance in general botanical theory, but they can be resolved only by breeding experiments Since six years are required on the average to bring a tulip seed to the flowering stage and two or three generations are necessary, I am trusting to some successor eventually to work out the material I am initiating

Herein lies the great value of a research foundation like the John Innes Horticultural Institution, it can embark with some confidence upon a scheme of work that may require a long term of years for its completion The genetics of fruit trees affords a case in point, a generation is rarely less than seven years with apples, plums, and cherries, and although Mr Crane has already obtained results of prime importance, they still open up fresh vistas of more extended work

Considering the magnitude of British interests in the tropics and the fact that all progress in the improvement of tropical crops like copra, rubber, tea, coffee, etc, depends upon genetical work, it is lamentable to see how little recognition the subject still receives either in our universities at home or in our experimental stations overseas

June 22, 1887—Prof Julian Huxley, honorary lecturer in zoology at King's College, London

I am myself especially interested in various lines of work bearing directly or indirectly upon the relation of hereditary constitution to adult characters such problems as the effects of individual genes during development, the study of changes in relative size of organs with growth, and the systematic study of gene-expression under different environmental conditions

I am also much interested in the species problem, and wish that a concerted attack could be directed upon it by a team including general zoologists as well as systematists, students of distribution, ecologists, biometricians, and geneticists I believe that a careful organisation of research in this field would be extremely fruitful

June 23, 1859 —Lieut -Col A W ALCOCK, C I E, F R S, I M S (retired), formerly professor of medical zoology in the University of London

Since my retirement from the London School of Tropical Medicine under the statutory age-limit, my efforts have been confined to supporting, under the auspices of the Tropical Diseases Bureau, what I hope may never be neglected, namely, the old and fruitful connexion between natural science and scientific medicine Authors of papers treating of animals specifically hurtful to the human frame, and zoological papers throwing light on causes, or suggesting means of control and prevention, of specific diseases of mankind, provide most of the material of this useful though non spectacular work

As a medico zoological subject for extremely promising study, I would direct attention to the wolf-reared children—one of whom I have seen—that occasionally come to light in northern India There is evidence that such children, having in infancy been carried off by wolves, have survived, have lived among the wolves, and (if by after chance rescued by capture) behave as wild animals But to what extent the germs of their human and intellectual endowment have been annulled or aborted in their aberrant wolfish environment is a subject that has never been precisely investigated It is plain that such exact investigation by a company of medical mentalists and biologists might be enormously instructive, in many directions, where confusion and fallacy now are somewhat prevalent

June 25, 1859 —Prof SYDNEY J HICKSON, F R S, emeritus professor of zoology in the University of Manchester, honorary fellow of Downing College, Cambridge

During the last three years the subject of my investigation has been the species problem in certain groups of Cœlenterata With this in view, I have completed a study of the Gorgonacea from the Panama region and of the Xeniidæ from the Barrier Reef In some genera there are apparently clearly defined discontinuous groups probably of the character of Linnean species, in others there seems to be complete continuity between the so called 'species' Satisfactory results as regards continuity can only be obtained when considerable numbers of specimens of a genus from one locality, or of species from several localities, are submitted to detailed investigation

The main object of this research is to throw light on the origin of species in a group of radially symmetrical and sedentary animals

June 26, 1894 —Prof P KAPITZA, F R S, fellow of Trinity College, Cambridge, and assistant director of magnetic research in the Cavendish Laboratory

The general line of our research is the study of the influence of strong magnetic fields on solid substances It is possible to trace the influence of the magnetic field on nearly all the known physical properties of substances We devote our attention mainly to studying the magnetisation of the substance itself, to the influence of the magnetic field on the binding forces between the atoms (magnetostriction) and to the disturbing effect of the field on the motion of free electrons in the crystal lattice (galvanomagnetic phenomena)

It appears that all these phenomena are strongly influenced by the physical state of the substance, and are much simplified if they are studied in undisturbed crystals The presence of foreign atoms, plastic deformation, and temperature agitation all seem to disturb the symmetry of the crystal lattice and hinder the appearance of the more simple laws which govern the phenomena in a perfect crystal lattice Should these laws be established they would probably have a more simple theoretical interpretation, since the crystal lattice is the most regular and symmetrical of all aggregates of atoms known in Nature

Societies and Academies.

LONDON

Royal Society, June 11 —**M L E Oliphant** Electron emission from Langmuir probes and from the cathode of the glow discharge through gases It is found that for potentials above about 600 volts the rate of increase of current to the probe is greater than that predicted by the original theory of Langmuir and Mott Smith, and this is ascribed to electron emission from the electrode, which increases with the energy of impact of the positive ions The energy delivered to the probes as heat has been measured by a compensation method which eliminates all corrections. From this energy and the potential of the probe relative to the surrounding space the positive ion current i_p can be obtained It is found that the ratio of electron to positive ion current is independent of the energy of the positive ions up to that corresponding to a potential of 600 volts, and thereafter increases The results are then discussed from the point of view of the angle of impact of the positive ions on the electrode surface, and it is pointed out that there must be an emission of electrons produced by agencies other than the impact of positive ions —**H E Watson, G Gundu Rao, and K L Ramaswamy** The dielectric coefficients of gases, I The dielectric coefficients of the five inactive gases and hydrogen have been measured at 25° and at − 190° or − 78° and compared with that of carbon dioxide None of these gases except argon has an electric moment detectable by the method of measurement employed, $0\ 05 \times 10^{-18}$ being an upper limit for krypton and xenon For argon the figure appears to be $0\ 03 \times 10^{-18}$, but this is probably a spurious result For the remaining gases it is not more than $0\ 015 \times 10^{-18}$ Further investigations of possible sources of error have been made, and an approximate method of determining condenser distortion with pressure is described —**G D Bengough, A R Lee, and F Wormell** The theory of *metallic corrosion, IV The effect on the corrosion of zinc of faster and slower rates of oxygen supply* than those used for previous papers has been studied, and some comparisons made with the corrosion of mild steel Complete curves are given showing the effect of concentration of potassium chloride and of potassium sulphate on the corrosion rates of zinc in tranquil conditions The influence of depth of immersion between limits of 0 35 mm and 100 mm has been ascertained An explanation has been found for the departure from linear corrosion rates after prolonged immersion in potassium chloride solution A micrographic study of the form and distribution of corroded areas has shown that very highly purified zinc yielded characteristic etch pits, but no preferential crystal boundary attack, less highly purified zinc rarely showed etch pits of definite shape, but marked preferential attack on the crystal boundaries

Geological Society, May 20 —**A A Fitch** The geology of the country between Ivybridge and Buckfastleigh, Devon The area described consists of a strip of the granite margin, the metamorphic aureole, and some rocks beyond the influence of the granite The physical geology is discussed and the presence of a relic of the 700–500 foot platform demonstrated by

planimetric measurements The rocks are described stratigraphically The petrology and petrogenesis of the resulting rocks are discussed in detail, and some aspects of two way migration considered The mineral assemblage of the aureole is not of much diagnostic value for the provenance of the sediments of the South of England Superficial deposits do not afford matter of great interest Economic aspects of the geology are dealt with

DUBLIN

Royal Irish Academy, May 11 —**J J Nolan** and **P J Nolan** Observations on atmospheric ionisation at Glencree, Co Wicklow The equilibrium of atmospheric ionisation was examined under conditions of wide variability of concentrations of condensation nuclei Certain diurnal variations of the concentrations of ions and nuclei were found The relation between ions and nuclei cannot be represented by a recombination equation of the ordinary type An empirical equation formerly proposed, involving the square root of the nucleus concentration, appears to fit the results better Both the ratio of positive to negative ions and the rate of production of ions appear to have a diurnal variation corresponding to that of the earth's field —**T McHugh** A pair of circular cubics generated by two rigid quadrangles When one plane moves upon another in such a way that a fixed quadrangle in the first plane is always in perspective with a fixed quadrangle in the second plane, the centre of perspective describes a circular cubic in each plane The relations and properties of these cubics are discussed and degenerate cases are examined

EDINBURGH

Royal Society, May 19 —**A D Peacock** and **R A R Gresson** Male haploidy and female diploidy in *Sirex Cyaneus*, F (Hymen) The work of Peacock and Sanderson on the more generalised Hymenoptera, the Tenthredinidæ, in which cells of connective tissue, blastoderm, embryo, and gonad have been examined, shows that the parthenogenetically produced male is haploid (8) and the bi sexually produced female is diploid (16) Further work, by Peacock and Gresson, on the wood wasp *Sirex cyaneus* F, supports the same view, for the spermatogonia and second spermatocytes are haploid (8), there is an abortive first maturation division, and the oogenia are diploid (16) Shortage of material has precluded study of the somatic cells Fuelgen's 'nuclealreaktion' is negative when applied to the large chromoid body and the cytoplasmic granules seen so prominently in spermatogenesis by the iron hæmatoxylin technique, their nature remains to be discovered —**Jessie A R Wilson** Some new facts about the structure of the cuticles in the Russian paper coal, and their bearing on the systematic position of some fossil Lycopodiales With a note on the absence of eligulate heterosporous Lycopodiales in the fossil record by **J Walton** A reinvestigation of the plant-cuticles extracted from the 'paper coal' from the Lower Carboniferous of the Moscow Basin has confirmed that the plants from which these cuticles have been derived were in possession of a ligule and must be classed amongst the ligulate lycopods Since there is no evidence of leaf cushions having been present on the older stems the cuticles are to be referred to the genus *Bothrodendron* A critical consideration of the known facts about the living and extinct Lycopodiales makes it clear that there are no known examples of eligulate heterosporous types —**A H R Goldie** The electric field in terrestrial magnetic storms Magnetically disturbed days magnify a peculiarity that is present in the diurnal variation of magnetic force even on quiet days, the magnification increasing with proximity to the auroral zone Using mainly the data of Lerwick, Eskdalemuir, and Abinger observatories, computations are made of the position, direction, and strength of electric currents capable of producing the displacements recorded during storms The heights found in individual cases range from less than 100 km to above 500 km, strengths are of the order of 500,000 amperes Midwinter and quiet years are characterised by currents low in strength and in altitude and considerably inclined to the W-E direction, summer and equinoctial seasons and disturbed years by the opposite features A chart is given of the electric current system in northern latitudes This system is derivable from currents generated mainly in the illuminated regions of the globe —**T M MacRobert** Fourier integrals This paper gives proofs, by the method of contour integration, of Fourier's double integral and of the Fourier-Bessel integral Two new Fourier Bessel integrals are then established, and also a Fourier-Legendre integral

PARIS

Academy of Sciences, April 27 —**Gabriel Bertrand** and **V Ciurea** Lead in the organs of animals In a previous communication regarding the occurrence and distribution of tin in animals it was mentioned that the sulphide precipitate contained other metals besides tin One of these is lead, and figures are now given for the amounts of lead found in various organs of the ox, horse, and sheep Generally, the distribution of lead and tin in the organs of these animals is similar, except in the case of the brain, which, in proportion, contains more lead —**L Cayeux** The core in core structure in schists Of the two hypotheses suggested for the explanation of the core in core structure, crystallisation and a pressure effect, the latter is found to accord best with the results obtained by the author from his examination of the Ordovician schists of Cabrières —**Ch Achard** and **M Piettre** The proteins of the articular effusion —**Paul Helbronner** A text of the third circular letter of Pascal relating to the cycloid (Dec 7 and 9, 1658) —**S Winogradsky** New researches on the micro-organisms of nitrification a description of a modified silica gel culture method, in which the gel is coated with a layer of an insoluble carbonate of an alkaline earth, the production of nitrate is accompanied by solution of the carbonate and consequent formation of translucent spots which can be counted —**A Buhl** The curvilinear propagation of invariant integrals The case of double integrals Corpuscular propagation —**D Wolkowitsch** The utilisation of Culmann's ellipsoid of inertia for the representation of an empirical law by an approximate formula with several parameters —**André Fouillade** A general theorem of iteration —**Arnaud Denjoy** Co-ordinated ensembles —**Paul Montel** Pairs of polynomials the zeros of which are inter related —**Edgar Baticle** The equilibrium curves of wires the elements of which are submitted to central forces —**P Dupin** and **Teissié-Solier** The alternate vortices of Bénard Karman and Reynolds's law of dynamical similitude —**S Choubine** The possible anomalies of resistance at low temperatures —**L Goldstein** The quantic mechanics of atomic shocks —**Drzewiecki** The application of Bernoulli's formula to the expansion of gases —**R Perrin** and **V Sorrel** An induction furnace with a ferromagnetic muffle and self-regulating temperature The muffle is made of ferrocobalt (30 per cent cobalt) and is surrounded by a closed conducting envelope (nickel) not magnetic at the working temperature With currents varying from 40 amp to 120 amp the temperatures varied only from 946° C to 972° C. The range of

special steels now available permits self regulating furnaces of this type to be made to work at any temperature between 150° C and 1100° C —**A Sesmat** The hypothesis of the curve of pursuit and Michelson's experiment —**A. Kastler** The structure of the Raman bands in liquids In the passage from the gaseous to the liquid state, the Raman bands are displaced in the direction of lower frequencies —**Ch Féry and Reynaud-Bonin** A non sulphating accumulator with high output A modification of the arrangement suggested in 1924, in which the access of oxygen to the negative plate is prevented The results of comparative tests on the commercial scale with ordinary and modified accumulators are given, and show clearly the advantages possessed by the latter —**P Brenans and K Yeu** Symmetrical halogenated phenols —**M G Filipesco** The siliceous rocks of organic and chemical origin from the Oligocene of the Carpathian mountains —**Albert Michel-Lévy** The conditions of deposit of the Perrier conglomerates (Puy-de-Dôme) —**C Arambourg** The longevity, in northern Africa, of the genus *Rhinoceros* during the Quaternary period Evidence from various sources tends to prove that the rhinoceros survived in North Africa up to a relatively recent date — **Maurice Villaret, L Justin-Besançon, and Jean Camus** The application of perfusion methods to researches of experimental hydrology concerning vaso motricity —**Albert Nodon** Observations on atmospheric detonations preceding solar and terrestrial disturbances —**Ernest Esclangon** Remarks on the preceding communication —**Mlle V Bossuyt and G Chaudron** Contribution to the study of the structure of textile fibres —**Pr Merklen, Mlle E Le Breton, and A Adnot** The influences of the lipoids of serum on the precipitation and estimation of the serum globulins The lipoprotein complexes of the serum exercise a hindering action on the precipitation of the globulins either by carbon dioxide or by neutral salts — **G Tanret** The trehalose of yeast Trehalose is found in high fermentation yeast to the extent of 2 per cent, but is not present in low fermentation yeast —**M A Machebœuf and R Wahl** Biochemical researches on the serum of patients suffering from lipoid nephrosis —**Marcel Labbé and F Nepveux** The sulphydric compounds of human blood in the normal and in pathological states

ROME

Royal National Academy of the Lincei, Nov 16 — **Maria Pastori** General expression for isotropic tensors —**V Hlavatý** Geodetic co ordinates Various considerations concerning Fermi's theorem on the geodetic co ordinates along a curve in *n* dimensional space are discussed —**G Krall** Critical velocities of heavy masses on a binary —**N Sakellariou** A class of central movements —**A Masotti** The electrical condenser formed by a rectilinear wire between two parallel planes The general case, in which the wire is not equidistant from the two planes, is discussed — **R Brunetti and Z Ollano** The Raman effect in pure water and in certain solutions —**V Puntoni** Morphological differentiation of certain species of Actinomycetes confused under the name *Actinomyces bovis* By a study of the process of formation of aerial mycelia, and of the sporification, differential characters have been established between *A sulphureus*, *A albus*, *chromogenus*, *A albido flavus*, and *A carneus* —**M. Mitolo**: The material metabolism of the central nervous system (3) The elimination of the cholesterol The complete elimination of cholesterol by surviving central nervous tissue is a phenomenon which may be established experimentally and is intimately connected with the metabolic processes of the tissue

Professionalism and Science.

ONE of the main features of the development of science during the nineteenth century, as Prof A N Whitehead has pointed out in " Science and the Modern World ", is the twin growth of technology and professionalism Science was then for the first time conceived as a vast mine of ideas for utilisation in practical life, and in the disciplined attack on problems thus encountered in technological developments the scientific worker rapidly passed from amateur to professional status

The professionalism of science is one aspect of the problem of specialisation which confronts the educationist to-day It can scarcely be disputed that the complexity of modern science and of industrial technology demand intensive specialisation and tend to encourage the growth of various scientific professions At the same time, the growth of professional organisations among scientific workers and the marked movement towards registration in post-War Europe, while likely to assist in the participation of scientific workers in public affairs, are not without their own special dangers

The specialised knowledge and restricted outlook of scientific workers themselves must be recognised as among the factors which have hindered the establishment of right relations between science and leadership Few scientific specialists could be named whose knowledge and opinions would be accepted as having much weight outside the narrow field in which they have elected to pursue their special studies or researches In many cases their training has not even equipped them with the powers of expressing the results of their work in forms which facilitate its appreciation and assimilation in the normal life of the community

It must be admitted that chemists, physicists, and other scientific workers are frequently characterised by a celibacy of intellect which curiously resembles the physical celibacy practised by the learned in the Middle Ages This celibacy of intellect on the part of individual scientific workers is one of the main causes of the ineffectiveness of their professional organisations, which are rarely able to secure sufficient support from the general body of members for the success of policies originated by a few more fertile minds If the future of society largely depends on our ability to link administrative power with knowledge of the scientific factors involved in our modern problems, that combination can only be secured when the scientific worker adds to his knowledge the wisdom which is the fruit of a balanced development

The problem is fundamentally educational Our present educational system on one hand produces administrators, frequently of a high order of ability, but whose complete ignorance of science renders them incapable of assessing the scientific factors upon which all our modern problems turn On the other hand, its tendency to excessive and premature specialisation produces a diversity of specialists often devoid of the political or social wisdom essential for the evaluation of the other factors involved

The problem of education must be faced by professional organisations of scientific workers if they are to assume their responsibilities of leadership The movement towards professional registration accentuates the importance of educational aspects of professional training It is essential that a sufficiently high standard of general education should be demanded of all entrants to such professions, that premature specialisation should be discouraged, and that qualification for entry to a profession of science should depend more upon the ability to apply and use knowledge than on the possession of an acquaintanceship with a mass of undigested scientific facts A danger of undue uniformity may arise, however, if the conditions of entry are too narrowly prescribed in closing a profession by a measure of registration In his recent book, "Education at the Cross-roads", Lord Eustace Percy has indicated the valuable contribution which the technical schools might make in a considered scheme of professional training

The technical school provides an important and valuable alternative method of recruiting the scientific and technical staff required by industry which may exercise a vitalising influence on professional policy and opinion out of all proportions to the numbers so recruited It also makes an important contribution to the solution of a problem which is encountered in every project for the registration of chemists or other scientific workers The efficient employment of research workers in industry is largely dependent on the existence of an equally or more numerous class of laboratory assistants capable of carrying out the routine testing or analysis and mechanical work Many such assistants acquire a high degree of experimental technique, although few have the capacity or training to originate experimental work

The career of laboratory assistant offers, however, very limited prospects Comparatively few laboratory assistants are able to qualify and enter a scientific profession by one of the recognised channels, nor is industry able to absorb such workers on its technical staff in adequate numbers Although the normal recruitment of the various scientific professions should not be from the ranks of such assistants, it would be unwise and unfair in any measure of registration to close the door entirely With proper support and co-operation, the training such assistants can obtain in the technical schools would enable them to attain the necessary standard of technique, and their more varied outlook and training might help to counteract the deadening uniformity which over-rigid conditions of entry tend to stamp upon a profession

Excessive uniformity is a real danger to professional life to-day It is fostered by the training which most scientific workers receive, and also by the conditions of industrial research with its emphasis on team work Nor is the policy of vocational selection without its tendencies in the same direction Fortunately perhaps, vocational guidance at present appears to exert only a broad influence on those proceeding to the universities, for example, as between arts and science It would be a serious danger if such methods were applied to guide into relatively narrow fields all intellects of a certain characteristic type and those alone

Scientific progress depends on more than mere advances in technique In the perfecting of technique and the evolution of corporate research or team work the professionalism of science has itself largely been developed Professionalism will, however, defeat its own ends if it succeeds to any great degree in cramping individualism and forcing on scientific workers a mediocre uniformity Progress depends on the spirit of adventure, and the spirit of science is one of questing and searching in the unknown, with its attendant risks of success and failure

The more economic necessity forces on scientific workers the development of their professional organisations, the more jealously they must cherish high ideals of craftsmanship and of service, and guard against the sterilising influence of excessive specialisation and uniformity Moreover, the very security which strong professional organisations ultimately confer on their members may itself be a snare to scientific workers

Security is but a means to an end, and a first effect of professional organisation should be to improve the conditions of employment of scientific workers, so that they can carry on their investigations without undue financial anxieties Such security makes for better workmanship by increasing the freedom of the investigator When, however, it becomes an opiate and the absence

of competition prevents the sharpening of mind on mind, security has outlived its purpose All powerful professional organisations tend to suffer from a species of inbreeding of intellect, or mental sterilisation, and it is not in an atmosphere of security and uniformity that great discoveries are made or creative ideas conceived

Specialisation is a necessary evil under modern conditions Professionalism is essential to maintain and advance high standards of technique and the due status of scientific workers Vocational guidance must play its part in reducing the wastage of human material in unsuitable occupations If in such ways the freedom, resources, and efficiency of the scientific worker are increased, it is incumbent upon him to see that there is no dimming of the spirit of adventure, the devotion to truth, the sincerity of purpose which are behind every great discovery of the past and still supply the driving force in the advance of science

Human Palæontology

New Discoveries relating to the Antiquity of Man By Sir Arthur Keith Pp 512 (London Williams and Norgate, Ltd , 1931) 21*s* net

THE last ten years have witnessed a profound change in the aspect of human palæontology Important fossils of hitherto unknown types of men and an ape (the Taungs Skull) have been found which reveal new and provocative information and add enormously to the range of facts that call for interpretation Such unexpected types of the human family as Rhodesian Man and ' the Lady of Lloyds' ' set new and intriguing problems The recent discoveries of representatives of *Homo neanderthalensis* in Gibraltar, Italy, Germany, the Crimea, and Palestine have extended the geographical range of this uncouth species and also given welcome corroboration to the generally accepted ideas as to the significance of Neanderthal Man and the part he played in human history More significant than all these discoveries are the important fossils found in China and the revelation of a new genus of the human family that is more primitive and generalised than any other type at present known The exceptional value of Peking Man, however, lies in the fact that he provides us with a bond of union between the other early members of the human family, whose fossil remains before the discoveries at Chou Kou Tien seemed to be irreconcilable with one another. At the present moment, with all this new and highly significant information collected from many scattered regions of the earth, there is an urgent need for a critical review of the whole evidence and an attempt to interpret its meaning The tempting task now for the first time becomes possible of achievement, of creating a solid and coherent foundation for a real science of human palæontology

For such a task, Sir Arthur Keith has opportunities and qualities such as no other anthropologist enjoys not merely the diligence to collect the widely scattered data and the literary skill and vivacity of style to make the new information intelligible to the man in the street, but also the freedom from the time-destroying interruptions from which those who hold university positions cannot escape

If Sir Arthur has not seized this chance in the way that would appeal to the serious student, he has rendered a useful service For the layman who wants to know what fossils have been discovered and what their meaning is, Sir Arthur has provided a useful and entertaining guide He begins with a full and well-balanced report on the Taungs Ape, for the rescue and interpretation of which he pays just and generous tribute to Prof Raymond Dart Most palæontologists will agree with his verdict *Australopithecus* is an ape closely akin to the African anthropoids, the chimpanzee and gorilla, and perhaps even nearer to the extinct *Dryopithecus*, which reveals quite definite, if slight, signs in its brain, face, and teeth of a nearer approximation to the human type than any other ape Obviously, however, the Taungs Skull itself is a relic of the survival into Pliocene or Pleistocene times of a type which must have come into being as early as the Miocene Hence this individual specimen cannot be regarded as a human ancestor, nor can its discovery in South Africa be regarded as shedding any decisive light upon the place of birth of mankind, since this ape's ancestors may have been, and no doubt were, wandering far and wide during the millions of years of Miocene and Pliocene time

Sir Arthur Keith adopts the views of Prof Davidson Black as to the significance of Peking Man, and he gives a clear and instructive report upon the excavations in China and the nature of the evidence provided by the fossils, the importance of which, he admits, it would be difficult to exaggerate There are, however, some significant omissions in Sir Arthur's commentary in particular, his neglect to use the illumination its evidence sheds on the Piltdown Skull, to which I shall refer later

The third major discovery discussed at length is

the Lloyds' Skull, found in the City of London in 1925 during the excavation of the site for the new building of the Corporation of Lloyds', and rescued for scientific investigation by Mr Warren R Dawson Sir Arthur rightly regards this tantalising fragment of highly fossilised skull as a relic of exceptional importance, which deserves exhaustive study and full discussion (As the custodian of this specimen, I can assure him that during the last two years I have been collecting the material for a monograph on the fossil, for which Miss Dorothy Garrod, Mr Warren Dawson, and Dr Matthew Young have written (1928) their valuable contributions) Later on, I shall refer to Sir Arthur's strange suggestion that this earliest Londoner belongs not to an unknown type of modern man, but to the Piltdown type !

An excellent summary is given of the new discoveries of men of the Neanderthal species and of men of more modern type in South and East Africa, Australia, America, and elsewhere, and some not altogether relevant disquisitions on the archæological work of Mr Woolley in Sumer and the problems relating to the origin of early civilisation

Taken as a whole, the survey is useful and illuminating, brightly written, and illustrated with 187 diagrams, most of them excellent, with enough of unexpected and even sensational speculation to titillate the palate of the reader, which might otherwise have become jaded by the richness of anatomical detail While realising the justice of the appreciations of this book which have appeared in the lay press, it is essential that I should direct attention to aspects of Sir Arthur Keith's treatise which must make the teacher of university students hesitate to recommend it to his class The major disappointment I experienced in reading the book was that Sir Arthur did not seize the unique opportunity that presents itself at the present moment of building all the wonderful material now available into a coherent foundation of anthropological doctrine, drastically eliminating the errors of the past and the questionable speculations of the present Instead of doing this, he has introduced a new crop of daringly improbable speculations and retained many old fallacies concerning matters of obvious fact

So much confusion has already crept into the references to the Lloyds' Skull in the public press, that it seems desirable to explain the real situation with reference to the issue which more than any other focuses the argument of Sir Arthur Keith's book

Writing in NATURE of Nov 7, 1925 (p 678), I discussed the puzzling characters of the fragment of the very ancient skull found in London, which was particularly tantalising in that the most significant parts, front, base, face, and teeth, were missing. I pointed out in what respects it differed from both *Homo sapiens* and *Homo neanderthalensis*, but eventually reached the tentative conclusion (since confirmed by Dr Matthew Young's statistical analysis), which I expressed more definitely in the *British Medical Journal* (p 854) of the same date, that 'The Lady of Lloyds' ' was " an exceptionally primitive member of the species *sapiens* "

In the course of the discussion in NATURE, however, I mentioned that while the endocranial cast presented a general resemblance to some of the smaller Neanderthal casts (Gibraltar and La Quina), it differed from them in respect of other features, in which it " closely conforms to the type found in *Homo sapiens*, as well as, curiously enough, in the Piltdown cast (*Eoanthropus*) " Sir Arthur Keith seems to have transformed this simple statement into the assumption that the London skull was a link between *Eoanthropus* and *Homo sapiens* ! Thus, he says, it does not belong " to an unknown type of modern humanity, but to a recognised type of ancient man, viz , man of the Piltdown type " (p 32) It is scarcely necessary to say that there is no warrant for this view Yet if the opinion of Miss Dorothy Garrod is correct—and of that there seems now to be no doubt—that the fossil is at least as old as the beginning of the Mousterian (and not, as my geological advisers claimed in 1925, more recent than the Mousterian), the London skull is vastly older than any known example of the species *sapiens* Hence it may belong to a hitherto unknown species

In spite of this possibility, which is even a probability, the lack of the most distinctive parts of the skull suggests that for the present it is wiser to refrain from creating a new species, and regard 'The Lady of Lloyds' ' as a very early and primitive representative of *Homo sapiens* Even if we push back her age to the Early Mousterian (? or to the Acheulean) Age, that would afford no justification for assuming that she was a descendant of (or in any way closely related to) the Piltdown Man, who belongs to a different genus fundamentally distinct in every character Elsewhere in his book (p 290) Sir Arthur Keith estimates that 200,000 years (many geologists and physicists would multiply this figure by four) intervene between the age of Piltdown Man and the Mousterian phase of culture Hence it would impose an unduly heavy strain upon the imagination to bring the Piltdown

Man and the 'London Lady' into the same genus, even if they presented any real likeness to one another As they do not, we may confidently dismiss this sensational claim as an unwarranted speculation

Sir Arthur Keith's claim for a certain resemblance of the Lloyds' Skull to the Piltdown Skull is given a spurious plausibility because he still retains his erroneous reconstruction of the Piltdown Skull Anyone who looks at the Piltdown fossils (or even Mr Frank Barlow's excellent casts of the separate fragments) can see on the posterior border of the parietal the medial part of the lambdoid suture Sir Arthur ignores this patent fact and adds about a centimetre to the posterior border of the bone (see his Figs 95, 154, 155, and 157) to make a hypothetical suture, when the real one is already present on the fossil To this error, another is added by ignoring the median plane of the skull The middle line in Sir Arthur's reconstruction is more than half a centimetre to the right of its true place, and the consequent error in the breadth of the skull double that figure, more than a centimetre Not only so, but these mistakes compel him to dislocate the natural articulation between the parietal and temporal bones and so create an unnatural and monstrous reconstruction These are not questions of opinion, but of easily checked anatomical facts, to which in 1927 I directed particular attention, with illustrative figures, in my "Evolution of Man" (pp 70-81, Figs 17 24) As Sir Arthur tells us he is "throwing sparks into the smouldering fire of the Piltdown Controversy" (p 32), would it not be wise to abandon claims, the error of which any casual visitor to a museum can detect for himself? I have referred to this matter, however, not because of Sir Arthur's provocative challenge, nor because it disposes of his suggestion to include the Lloyds' Skull within the genus *Eoanthropus*, but also to direct attention to a matter which more than any other is causing confusion in human palæontology

The widespread suspicion of the authenticity of the Piltdown Man as a valid genus is notorious, and the chief reason for the lack of agreement in human palæontology Even to-day many Continental anthropologists refuse even to refer to it in treatises on fossil man or, when they do so, brush it aside as being so doubtful that it is best to ignore it I have been to some trouble to discover the reasons for the persistence of this attitude It is not simply because the Piltdown jaw is apelike in general form, so much as the claim that the braincase associated with it conforms to the type of *Homo sapiens* Hence it is particularly unfortunate that in this book Sir Arthur Keith not only persists in exaggerating the size of the braincase and brain, but also states that "the cranial features of Piltdown Man are essentially of the modern type" (p 32), and "if we had found only the cranial parts of the Piltdown Man we should never have hesitated in regarding him as the direct ancestral type of modern man, the simian features of his lower jaw and of his teeth led us to exclude him from this position" (p 546) There is no justification for such misleading statements In my "Evolution of Man" (1927) I showed that the Piltdown skull and jaw are not disharmonious, that the general architecture of the braincase is no less simian in character than the jaw In a series of comparative diagrams (Fig 24) I adduced the evidence in substantiation of this opinion

It is strange that Sir Arthur totally ignores the clear light the evidence of the Peking Skull throws on this aspect of the Piltdown problem For the peculiar characters of the natural skull of *Sinanthropus*, which is not the result of a reconstruction, reproduce in an even more exaggerated form (especially in the view of the braincase from behind) the peculiar features of the true Piltdown reconstruction to which Sir Arthur has been objecting for seventeen years (see Nature, Oct 16 and Nov 6 and 20, 1913)

In the days when most anthropologists refrained from estimating the antiquity of man in numbers of years, Sir Arthur Keith used to juggle with big figures in his speculations More recently, when using the exact methods of physics, the reasonable probability of a figure approaching a million years has been shown to be the sort of date to assign to the beginning of the Pleistocene period, Sir Arthur has cut down his figure to 200,000 years Many years ago Profs Joly and Boltwood (1908), among others, suggested the value of radioactive changes in rocks as a geological chronometer Holmes and Lawson (1927), Kovarik (1930), and von Hevesy (1930) measured the natural disintegration of uranium into lead in the oldest igneous rocks containing radioactive elements and arrived at an estimate of 1,825,000,000 years for the earliest actual sample, or in round numbers about 2,000,000,000 as the possible age Using the time scale which geologists have gradually determined since William Smith in 1796 made the first estimate, there is little room for doubt that the end of the Pliocene can be referred to a time which is one two-thousandth of the whole scale—in other words, roughly a million years ago

Recent researches on this problem have been clearly summarised by Dr Chester A Reeds in an article entitled "How Old is the Earth?" in *Natural History* (March–April 1931) Assuming the reality of Pliocene Man, Dr Reeds suggests that the antiquity of man must be at least 1,500,000 years Against these results inferred from exact investigation Sir Arthur Keith attempts to justify his estimate of 200,000 (later in the book he makes it 250,000) for the Pleistocene period by the statement "My reason for reducing the time allowance was based on the results arrived at by students of early man's stone tools, his industries or cultures" (p 34) But this is sheer guesswork For who can decide whether Acheulean implements, which are admitted by him to have undergone no change in forty thousand years, might not also have remained under the thraldom of tradition for another forty thousand years?

If Sir Arthur whittles down the time allowance for man's early history, he runs riot in his estimates of the duration of the later phases of culture Ignoring the general trend of archæological research during the last two decades, he allows eight thousand years for the Neolithic period He does not explain what precisely he means by the discredited term 'Neolithic', or whether it refers to Britain or the Continent If the former, eighty would be much nearer the mark than eight thousand —the time it took for the use of bronze to spread from the Continent to England after the people of the former introduced the Neolithic culture in the process of getting tin from Cornwall for bronze-making

Although Sir Arthur Keith devotes only a page and a diagram to chronology, I have directed particular attention to the important questions at issue because they seem to be of crucial significance in a work bearing the title "Antiquity of Man" It is surprising, therefore, that Sir Arthur while continuing to use this title has ignored the significant work the physicists have been doing to solve the essential problem implicit in his label

It comes as a relief to find that Sir Arthur has at last abandoned his claims for a high antiquity for the Galley Hill Skull, an opinion that has always played an obtrusive part in shaping his attitude in the reconstruction of human history The vacant niche in his pantheon of our remote ancestry he now assigns to 'the Lady of Lloyds'', the oldest known inhabitant of London The fact that her skull is truly fossilised and was found in a geological deposit of remote antiquity gives her a very much stronger claim than Galley Hill Man to this honourable place Yet in abandoning the Galley Hill claims Sir Arthur also seems, at the moment when for the first time there is reasonable evidence in support of it, to have given up one of his favourite slogans—the remoteness of the antiquity of the modern type of man, even repudiating the views of his disciple Mr Leakey, whom for three years he has encouraged in his theories for assigning extreme antiquity to the human remains and associated cultures in East Africa Instead of emphasising the fact that although the Lloyds' Skull cannot be brought into strict conformity with either *Homo sapiens* or *Homo neanderthalensis*, it is probably a very ancient and primitive forerunner of *Homo sapiens*, he wants to associate it with the Piltdown Skull and to overcome the burden of incredibility by claiming that *Eoanthropus* is modern in type

In his writings Sir Arthur Keith has never shown much respect for the commonly accepted principles of biology, in particular those involved in questions of phylogeny In the present work he provides us with new examples He suggests that the Australian race (*Homo sapiens*) may have been derived from the genus *Pithecanthropus* (p 312) and the original owner of the Lloyds' Skull from the genus *Eoanthropus* yet he seems to regard both the Australian and 'the Lady of Lloyds'' as members of the genus *Homo*! Unfortunately, the diagram that forms the frontispiece does not enlighten us as to the means whereby this miracle was achieved

It is puzzling to know why Sir Arthur added the last two chapters They add nothing to our knowledge or the general argument of the book, but suggest rather that he is not serious His statement that he is going to make endocranial casts "intelligible to those who have not served an apprenticeship to anatomy", is scarcely justified by his conclusion, which is expressed in the words "I suspect that a large brain was given to man, not that he might understand life, or circumvent difficulties, but simply to enjoy it" Even more surprising is the last chapter In it he seriously discusses the possibility of an isolated example of a species of man other than *Homo sapiens*—the chapter is entitled "The Discovery of *Homo Gardarensis*—surviving in Greenland in the twelfth century A D" In the end he admits that the man was suffering from acromegaly—and uses the opportunity once more to suggest that extinct types of the human family were subject to pituitary disturbances, but without being pathological or, in fact, suffering from the usual disabilities of such lesions

I have directed attention to the weak spots in the book to make it plain why teachers who urgently need a sober presentation of the facts of human palæontology must hesitate to recommend it to their students Nevertheless, it is full of valuable information and, except in the lapses that I have enumerated, serious argument It need scarcely be said that the book is vastly entertaining

G ELLIOT SMITH

The New Popular Science

(1) *Everyday Marvels of Science a Popular Account of the Scientific Inventions in Daily Use* By V H L Searle Pp 208 (London Ernest Benn, Ltd , 1930) 10s 6d net

(2) *This Scientific Age Essays in Modern Thought and Achievement* Edited by Dugald C Jackson, Jr , and Prof W Paul Jones Pp vii + 353 (New York John Wiley and Sons, Inc , London Chapman and Hall, Ltd , 1930) 10s net

(3) *Master Minds of Modern Science* By T C Bridges and H Hessell Tiltman Pp 278 + 32 plates (London, Bombay and Sydney George G Harrap and Co , Ltd , 1930) 7s 6d net

(1) IT may be that, strictly speaking, there is no such thing as popular science, new or otherwise that science can never, in the strict sense of the term, become popular, and that it is more proper to speak of the popular approach to science There are, however, many new methods of approach to-day, pleasant paths and by ways that can be travelled without tears, and these three books bear eloquent witness of this They also strongly refute the idea that this type of book is apt to disparage the dignity of science or be unworthy the notice of true research workers For it must be emphasised, in the first place, that any real or imaginary gap between men of science and the people is becoming constantly narrower in several different ways, some of which will be here briefly noted , in the second place, the writing of so-called popular books on science is often very much more difficult and requires qualities of a different and sometimes higher intellectual calibre than does the writing of a professional text-book , and in the third place, they are often of great help to the scientific worker himself

The greatest minds have never, throughout the world's history, disdained the task of trying to reach the popular ear and heart, and the same is more than ever true to-day Also, it was never more urgently necessary than now It is a great and indispensable task

The distance between the man of science and his fellow-men is rapidly decreasing, and is being replaced by a close relationship more complex, more profound, more significant every day Science to-day enters more intimately into the daily life of the individual and its achievements meet him at every turn As Dr Murray very finely says in his foreword "The phenomenal advances of science and of its industrial utilisation, its establishment in schools and colleges, and its domestication, so to speak, by wireless sets and the like, have bred in these days a scientific consciousness of a novel and formidable kind" Who can doubt the wondrous growth of this scientific consciousness among the people, and the urgent need for its stimulation and guidance in the right spirit and in the right direction, could we but discern precisely what is right ? We may fairly safely claim, then, that the people have risen to a somewhat higher plane in intelligent appreciation of things scientific, and that, again quoting Dr Murray, the "mild thrills and genteel dilettantism of the Victorian lecture room have given place to a stronger spirit"

Then again, the gap is narrowed by a change of attitude in the man of science himself Has he not become more human, possibly even more humble ? He may even yet come to realise that he himself, like the rest of mankind, is a wholly insignificant nonentity in a universe growing ever more wonderful, mysterious, and grander as he advances in knowledge, and will be assiduous in passing on this fact to his fellows, as indeed some are already doing It is far more rational to exert himself to the utmost to invoke the people's interest, help, and sympathies, and, like Mr Searle, enjoy nothing better than a talk with the man in the street True, Mr Searle's excellent book is really intended for the intelligent boy, but in matters of science we are all boys—or girls—and this book may be read and enjoyed by intelligent youngsters up to ninety or more, whether professed men of science or not

(2) It is a rather surprising fact, though it needs but little reflection to establish it, that much of that which now comes within the category of popular science—the new popular science—is of considerable value to the man of science himself It will be obvious indeed, in these days of extreme specialism, how very helpful such books can be to the man who, closely and narrowly specialising in one small corner, wishes to know something of the whole world of science in general, and of literature too Mr Searle's book, as we have already noted is intended primarily for the intelligent youth—that

is, in many cases, for the scientific worker in embryo—and though of the 'popular' kind, it will prove extremely stimulating to the student of any branch of science, but this, our second book under review, is of an entirely different sort, and takes a wider range The editors may perhaps feel that it does not strictly belong to what is commonly understood as 'popular' scientific literature, yet, from what has already been said above, they will assuredly not have any ground for mortification or scent any sort of stigma or degradation

The work, a collection of essays by eminent thinkers on both sides of the Atlantic, including H G Wells, Dean Inge, Sir Richard Gregory, Ray Stannard Baker, Edwin E Slosson, will provide an intellectual treat for any man, whether scientific worker or layman, and for the specialist it will be a welcome and refreshing diversion The editors are justified in their hope that the book will meet the needs not only of technical students for whom it is directly intended, but also will appeal to a far wider circle Sir Richard Gregory writes on "Practical Purpose"—science justified by its works, a favourite theme, with which he deals in a masterly manner, H G Wells and others write on specialisation, Ernest Dimmet on the art of reading, Dean Inge on success—one of the most cheerful disquisitions in the book, M Luckiesh on "Men, Atoms, and Stars", which makes us shrivel into nothingness, and Maurice Holland on the "Voice of Research", which makes us swell into visibility once more As a combination of great science and great literature, the book is unique, and wonderfully exhilarating

(3) With "Master Minds of Modern Science" we feel on surer ground, at least, as regards categories and classifications This is unmistakably a popular science book, rather of the older than the newer type, and describes the work of leading modern scientific workers, but, though fairly comprehensive, it is evident that someone or other is bound to find gaps It is no doubt a useful contribution to the history and biography of scientific achievement The chapter on Luther Burbank and his work, the wizard of the garden, is of particular interest, for his work is not perhaps so well known in Great Britain as it should be, especially when we reflect that we are a nation of enthusiastic amateur gardeners The book has some excellent illustrations, is well printed in large type, and for those who wish to gain a general idea of some of the recent achievements of science it can be thoroughly recommended W G L C

Our Bookshelf.

Up and Down in California in 1860–1864 the Journal of William H Brewer, Professor of Agriculture in the Sheffield Scientific School from 1864 to 1903 Edited by Francis P Farquhar (Published on the Foundation established in Memory of Philip Hamilton McMillan of the Class of 1894 Yale College) Pp xxx + 601 + 32 plates (New Haven, Conn Yale University Press, London Oxford University Press, 1930) 27*s* net

THE author was the well known professor of agriculture in the Sheffield Science School of Yale, and sometime president of the National Academy of Sciences In 1860, as a young man, he joined J D Whitney as principal assistant in the new Geological Survey of California, which it was hoped would advise as to the future development of the mining industry, then in dire distress A second part of the work was to report on the plants and animals, and to Brewer was assigned the former Whitney, with a love of thoroughness, made it primarily into a topographical survey, upon which the geology could be charted His action here undoubtedly trained the men and set the standard on which the whole United States was mapped Brewer led the first field party, and his letters now published show him directing and carrying out every class of work, except botany This he continued to do until 1865, the survey being continued to 1873, dying itself but giving birth to the Federal Geological Survey Department in 1879

Brewer was a voluminous letter-writer, and he numbered his letters serially, as he did his plants He zigzagged across California from south to north, and he always wrote what he saw, seldom what he heard Consequently, we have an account here of California as it was in 1860–65 It tells of the mountains and valleys, of the mines and of the plantations, of the old Latin civilisation and of the Indian missions, of the Indians themselves and of the westerners, of the animals and of the plants It is all simple, the life and work of a camping party and of the people they met There are no striking adventures, no sensational discoveries, merely an account of trails and conditions in a yet unopened country As an example may be mentioned Brewer's letter on the Yosemite Valley and its waterfall of 2600 feet, a far simpler but more compelling account than any of the numerous, often exaggerated stories of this famous canyon The letters are a record beyond price to future historians of California, but they are too local to be of general interest, too domestic to allow scope for wider deduction or speculation They serve their purpose in the history of the United States, and this is further served, for their editor has chosen to illustrate them by contemporary drawings and prints

The Balancing of Engines By Prof W E Dalby Fourth edition Pp. xii + 321 (London. Edward Arnold and Co, 1929.) 21*s* net.

THE necessity of balancing steam engines was first felt in connexion with locomotives, and so long ago as 1834 Bodmer patented a method

which was tried with some success about ten years later Many horizontal marine engines were fitted with balance weights on the cranks, but balancing became of far greater importance with the introduction of fast-running engines for driving electric generators and torpedo craft, and with the construction of very large triple-expansion engines for Atlantic liners Readers of the life of Sir Alfred Yarrow will recall his experiments on vibration made aboard the *Majestic* during a trip to America in 1890 experiments which led to his collaboration with Dr Otto Schlick in the introduction of a design of a balanced four-cylinder engine

Papers on balancing were read to the Institution of Naval Architects and the Institute of Marine Engineers by Schlick, Yarrow, Malloch, McFarlane Gray, and others, and it was to the former Institution Prof Dalby read his important papers on the balancing of marine engines of 1899, 1901, and 1902 In 1901 he dealt with the balancing of locomotives, in a paper read to the Institution of Mechanical Engineers, and the following year he published the first edition of his well-known text-book In these papers and text-book he introduced the idea of a reference plane and a schedule by means of which a draughtsman could find the balance weights for a complex system of masses about an engine crank shaft, and his methods have been used all over the world The work of balancing locomotives has recently assumed a new importance through the experiments of the Bridge Stress Committee, and in view of this, Prof Dalby in the fourth edition of his text-book has added a chapter dealing with the work of the Committee and at the same time has rewritten the chapter on locomotive balancing A new chapter written for this edition, on the balancing of internal combustion engines, will be found of great use to those concerned with the design of engines for motor cars, aeroplanes, and motor ships

Photochemistry By Dr D W G Style (Methuen's Monographs on Physical Subjects) Pp vii + 96 (London Methuen and Co , Ltd , 1930) 2*s* 6*d* net

THE introduction of a volume on photochemistry into this well-known series of monographs on physical subjects, gives us an indication of the rapid change which has occurred in the study of the chemical action of light by the introduction of the Stark-Einstein law of photochemical equivalence in the primary light process, and of the work of Franck on the interpretation of band spectra and their significance in indicating the process of molecular dissociation This small volume is well and clearly written and is by no means uncritical Attention is directed first to the primary light process, and the possible subsequent reactions which the photo-excited molecule may undergo are then discussed in some detail A little more concerning chemi-luminescence and fluorescence might well have been included in these sections The fourth chapter is devoted to a consideration of the still debatable problems connected with the dependence of the quantum yield on temperature and wave-length, and the volume concludes with a brief summary of the experimental methods adopted in photochemistry

Although a rather slender volume, the reviewer can subscribe to Prof Allmand's introductory remark that the volume can be recommended with confidence to students and research workers E K R

The Statesman's Year Book Statistical and Historical Annual of the States of the World for the Year 1931 Edited by Dr M Epstein Sixty-eighth Annual Publication, revised after Official Returns Pp xxxiv + 1462 (London Macmillan and Co , Ltd , 1931) 20*s* net

THE new issue of this valuable work of reference has again been thoroughly revised in the light of official statistical publications Many annual returns for 1930 are included, and in some respects the revision is even later Mention is made of the change of political status in Spain The year was one of census enumeration in several countries, and new figures are included for the United States, Hungary, Norway, Switzerland, and several other countries The introductory tables record world production of coal, oil, iron, steel, and some other commodities An extension of these tables is one of the few improvements that it is possible to suggest Two coloured maps show respectively the administrative divisions of Yugoslavia and the status of South American boundaries, with the areas that are still in dispute A welcome feature of this year book is the small bulk, which is retained from year to year

Modern Psychotherapy By Emanuel Miller (Modern Treatment Series) Pp 131 (London Jonathan Cape, Ltd , 1930) 5*s* net

DR MILLER is to be congratulated on a very readable and concise work He does not unduly stress only one aspect of the subject, as so many modern writers do , but provides us with a well-balanced summary of the three main schools of psychoanalytic thought The author takes a very sensible attitude towards the treatment of the psychoses by psycho-analysis Although psychoanalytic theory may explain the mechanism of a great many psychotic symptoms, it does not explain their cause and certainly does not supply a useful therapy The author wisely points out that "full understanding can only come through personal contact with cases and through sympathetic understanding of what are very real and very painful disorders" Psychological medicine is not learnt in the laboratory with the experimental psychologists , but in the infinitely more difficult school of contact with life and its problems

The Gardener's Year By Karel Čapek Pp 160 (London George Allen and Unwin, Ltd , 1931) 3*s* 6*d* net

THIS very entertaining volume with its delightfully humorous pictures should be read by all gardeners The text is as amusing as the illustrations, and though in no way scientific, much common sense underlies the humour to be found on every page

Letters to the Editor.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE *No notice is taken of anonymous communications*]

A Simple Method of Investigating Wireless Echoes of Short Delay

ONE of the two methods most commonly used in the determination of the equivalent height of the Kennelly Heaviside layer is that involving the measurement of the time required for a brief wireless signal to travel upwards to the reflecting region and back This quantity is most conveniently determined by causing an emitting station to send out very short pulses of radio frequency energy, and measuring, at a point a short distance away, the difference between the times of arrival of a particular signal pulse via the ground and via the upper atmosphere

Various methods of producing the short pulses required have been used,[1] but in all cases a somewhat elaborate modulating device has been necessary We

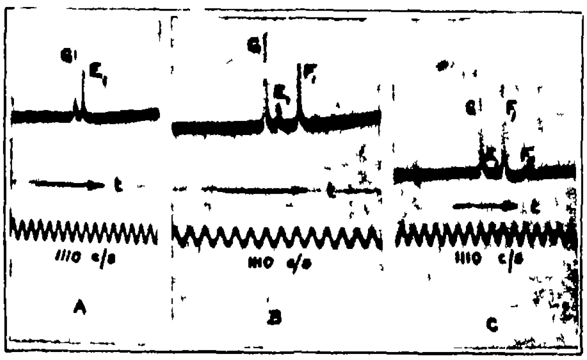

FIG 1

have found, however, that it is possible to dispense with any special modulating system for controlling the emission from the oscillator and still obtain pulses of satisfactory type If the grid leak of an ordinary triode oscillator is increased to a relatively high value, the generator itself produces suitable short pulses of radio frequency energy alternating between uniform periods of quiescence By adjusting the grid circuit constants, both the duration of the pulse and the duration of the interval between successive pulses may be controlled This peculiar property of a triode oscillator working with a high grid leak has been previously investigated in connexion with its use for providing a unidirectional time scale for cathode ray oscillography[2]

Using an emitting station at East London College, London, E 1, working on a wave length of 80 metres, and emitting pulses of about 0 0003 sec in duration, spaced 0 02 sec apart, we have been able to record photographically at King's College, London, W C 2, 3 miles away, the reception of these pulses and their echoes from the Kennelly Heaviside layer A satisfactory arrangement for studying the characteristics of such echoes is to use a dual observational system consisting of a cathode ray oscillograph and a high-speed recording oscillograph (Duddell type) The received pulses can normally be watched as a recurring image on the cathode ray oscillograph, using a linear time base of stroke frequency coinciding with the pulse frequency, but, when it is desired to obtain a permanent and more accurate record of any particular combination of echoes, the high speed oscillograph with a suitable time scale calibration can immediately be switched into use

Some specimen records, taken on June 15, between 1800 and 2000 G M T are shown in the accompanying diagrams (Fig 1) In each case the first impulse (marked G) is that received direct via the ground, the subsequent pulses being due to waves reflected by the upper atmosphere The records are of interest in confirming results previously obtained in England using the frequency change method of measuring equivalent heights, in that they indicate reflections from two regions at different heights in the upper atmosphere Record (a), taken at 1830 G M T, illustrates a singly reflected pulse E_1 from the lower of these two regions (Region E) Record (b), taken at 1850 G M T, shows a singly reflected pulse E_1 from the lower region and a singly reflected pulse F_1 from the upper region (Region F) Record (c), taken at 1910 G M T, shows that, as sunset (2020 G M T) was approached, the singly reflected pulse E_1 from the lower region was less intense, while that from the upper region F_1 was much more marked A pulse F_2 indicates double reflection from the upper region

This work is being carried out as part of the programme of the Radio Research Board of the Department of Scientific and Industrial Research

The Atomic Weight of Xenon

BY the kindness of Dr F W Aston, who placed at our disposal 235 c c of highly purified xenon, we have been enabled to redetermine the atomic weight of this element

Using a highly accurate micro balance, the design of which will be published shortly, we have measured the pressures of xenon and pure oxygen at which the densities of the two gases are equal This has been done for two different densities, corresponding to pressures of xenon of about 80 and 153 mm The two ratios PO_2/PXe when all corrections were made were found from two series of very concordant readings to be 4 1035 and 4 1049 respectively at 18° C

The limiting density is obtained by extrapolating these two ratios linearly to zero pressure, and is 4 1020 At such a low pressure as 80 mm a linear extrapolation is certainly legitimate, as any curvature would be quite beyond the limit of error of our measurements Hence the atomic weight of xenon is $4\ 1020 \times 32 = 131\ 26(4)$ The error of measurement does not seem to be greater than $\pm 0\ 005$ This agrees remarkably well with Dr Aston's value, $131\ 27 \pm 0\ 04$, derived from the measurement of the intensities of the lines of the various isotopes in the mass spectrograph[1]

The gas supplied to us was originally very pure It was fractionated a number of times, until further treatment of the heaviest fraction gave no increase in density

It may be noted that after the first fractionation the difference in balancing pressure between the first and last fractions was only about one part in 900

The Supposed Resting Stage of *Limnocnida Indica* Annandale.

THE life history of this fresh water medusa has been a baffling problem since its discovery twenty years ago [1] The jelly fish occurs in certain rivers flowing down the eastern slopes of the Western Ghats of the Bombay Presidency during definite seasons of the year (March to May) What happens to the species during the rest of the year has been more or less a mystery From the fact that it occurs year after year in certain parts only of these rivers, it has been supposed that there is a fixed asexual hydroid stage in the life cycle of the animal, which buds off medusæ at the commencement of the hot weather [2] Although

FIG 1 ×50

the medusæ were kept under observation in the field, and a careful search for the hydroid stage made on more than one occasion, no clue to the mystery was obtained Nearly eight years after the discovery of the jelly fish, the late Dr Annandale, as a result of further observations, recorded his opinion that the species "must have a fixed or resting stage in its life history, perhaps with the structure of a minute hydroid, or more probably encysted in a form that would not be recognisable with our present knowledge" [3]

While on a recent tour to Medha (Satara Dt, Bombay), where the species was first discovered, I found certain very minute bodies in great abundance at the bottom of a deep rock pool in the course of the Yenna River, sticking to minute particles of mineral matter (Fig 1) They are of different sizes (0 15–0 34 mm in diameter) and in various stages of development, from the presumably early spherical form to the fully developed capsule like or oblong form, but the latter are much more numerous than the early or intermediate forms They have a transparent covering of apparently chitinous matter with pits and minute pores on the surface The cavity of the body is more or less filled with refringent spherical granules in a clear, sticky, viscous fluid In the early spherical form there are numerous minute elastic and sticky threads issuing through the pores on the surface which serve to anchor it to particles of mineral matter The more advanced oblong form is, however, attached by a short, stout, elastic stalk which is composed of minute threads of sticky material aggregated together with inclusions of foreign matter between them The surface of the external covering is distinctly pitted, with traces of minute pores in each pit In what appear to be the very advanced forms, the granular material forms a few large spherical masses clustered together like a bunch of grapes It appears probable, from the occurrence of a few empty bodies with their external covering ruptured, that the spherical masses on completion of development within the capsule find their way out

It will be of interest to add a chance observation which I have made on a small number of medusæ, male and female, from the Koyna River near Karad (Satara Dt, Bombay), kept in a small glass aquarium At the end of the day of capture, a gravid female discharged its eggs, many of which settled down at the bottom of the aquarium Examination of the eggs under the binocular microscope showed that they were attached to the bottom by means of minute elastic threads from the surface of the eggs They were spherical in form, had a thin, transparent apparently chitinous covering with minute pores, and were filled with a viscous fluid containing numerous refringent granules The remarkable resemblance between the discharged eggs and the early stages of the so called resting bodies suggests a clue to the life history of the jelly fish Evidence to prove that the egg passes directly into the resting stage, and that the medusæ have their origin from the resting body without the intervention of a hydroid stage, is still incomplete It seems probable, however, that the so called resting bodies lie dormant during the rainy and cold seasons, and discharge their contents at the beginning of March in the form of very minute medusæ, which do not generally rise to the surface until they have attained to a comparatively advanced stage of development, and that a fixed hydroid stage is altogether omitted from the life cycle

These resting stages or bodies are still under observation, and a detailed account will be published in due course in the *Records of the Indian Museum*

Potential Temperature and the Stratosphere

THE high coefficients of correlation between the measures of certain meteorological elements at the tropopause and the air pressure at 9 kilometres cited by L H G Dines in his letter in NATURE of May 30 may be welcomed as a reminder of the intricate but regular associations of the meteorological elements in the sequence of weather changes which are so vexatiously irregular at the surface

It is worth noting that, according to the data given by W H Dines, the 9 kilometre level is the level at which the relation of pressure to temperature along the horizontal is normally that of the dry adiabatic so that dry air might travel up gradient or down-gradient, along the horizontal, without exciting any resilience

I mention this because when Mr Dines's letter refers to the enormous stability in the stratosphere on account of the isothermal condition in the vertical I am prone to think of resilience, and while allowing

that if I lift air vertically I shall find vigorous resilience, I shall find no resilience in air moving along a surface of equal potential temperature whether the motion be up gradient or down gradient, up hill or down hill Along an isentropic surface up hill coincides with up gradient above 9 km, but with down gradient below that level Consequently, I have no difficulty in visualising an automatic flow of air up hill or up gradient provided the isentropic surface shows the way That is a kind of flow which is almost unthinkable at the earth's surface but possible in the free air, and may bring the high correlations within the sphere of recognised probability

I may take the opportunity to remark upon the great change of mental attitude towards the general atmospheric problem that is natural to the contemplation of the conditions of the free air Any time within the past fifty years, judging by what happens at the surface and in the laboratory, I should have had no objection to offer to the suggestion that pressure gradient means potential energy, which might be sacrificed to produce velocity of air or natural wind, and now, if I think of pressure-gradient as the deformation of an isobaric surface from the horizontal by the shifting of air mass, as it must be, I find that the energy obtainable by the levelling of a hump must be spent in filling up a hollow, and apart from difference of entropy there is nothing available to produce kinetic energy

In the upper air, pressure gradient and wind-velocity automatically increase and decrease together So pressure gradient comes to be the mere index of the response of an air current to the 'centrifugal force' of the earth's rotation, aided or counteracted by any local curvature of the air's path

In this way, centres of local circulation, whether of low pressure or of high pressure, take quite a different place in the hierarchy of atmospheric influences from that which in the past century they have been supposed to occupy The real dynamical agents of the free air are the currents which find their cartographical expression as the straight isobars running between high pressure and low pressure, riding 'side saddle' on the gradient The high and the low are mere incidents of the relative motion of air currents of different directions In the northern hemisphere wherever the passing currents keep the English rule of the road, with opposing traffic on the right, high pressure (and generally fine weather) between them is the inevitable consequence, but wherever the atmosphere adopts the continental rule of keeping the opposing traffic on the left, there a 'low' between them is equally inevitable

The concentration of attention upon centres of high or low pressure, which are practically points of no motion, instead of upon the air currents which cause them, is a curious aberration of dynamics It is to some extent like concentrating attention on the point of contact of a wheel with the rail as the important point of influence in a dynamical system of that character

There would be little to choose between the importance of the effects on either side of a travelling current if the air kept 'dry', the real trouble begins when the juxtaposition of the currents from different directions brings the temperature of air below its point of saturation—then an enormous release of energy from its store in the water vapour of the air with little sacrifice of temperature, and in consequence all the dynamical and physical features of the cyclone and the depression

These conclusions follow from the assumption of an automatic balance between wind velocity and gradient, under the influence of the earth's rotation, which is not likely to be appreciated by those who fix their attention on the behaviour of air at the surface, but which deserves consideration when the causes of the high correlations of the upper air are being sought

From this point of view the interactions of air-masses within the regions of cyclonic depressions which the Norwegian school of meteorologists has turned to such profitable use within the past twelve years are the by-play and 'asides' of the main atmospheric drama under the influence of the surface friction They are complicated by the release of the energy stored in water vapour wherever condensation is set up

Calculation of the Latent Heat of Fusion of Camphor from Vapour Pressure–Temperature Data

IT was recently pointed out [1] that of the two available values, namely, 400 and 498, for the molecular depression of freezing point (K) of camphor, the larger figure seemed the more correct, because it had been subjected to an *a posteriori* verification by its discoverer Jouniaux,[2,3] and, secondly, because the smaller value had been drawn from a fusion point diagram [4] of doubtful accuracy [5]

Briefly, Jouniaux's proof consisted in deducing the latent heat of fusion of camphor (L_f) from his own value for K and comparing the result with the figure obtained by calculation from quite different physical measurements recorded in the literature by other workers This he accomplished as follows, using the equation $L_f = \frac{T_f}{E}(v_l - v_s)\frac{dP}{dT}$, where p is vapour pressure, v_l and v_s are specific volumes of liquid and of solid, E is the mechanical equivalent of heat, and T is the absolute temperature

The quantity v_l was obtained from Kuhara's measurements [6] of the density of liquid camphor at 205° From three vapour pressure temperature measurements for camphor selected from the data published by Ramsay and Young,[7] Allen,[8] and Vanstone,[9] the constants m, n, and z in the Kirchhoff Dupré Rankine [10,11,12] equation $\log_e p = \frac{m}{T} + n \log_e T + z$ were evaluated as $m = -2108\ 72$, $n = 10\ 1142$, and $z = -51\ 1692$ Putting $T = 451\ 6°$ (melting point of camphor) in this equation, the value of p at the melting point of camphor was found to be 398 7 mm, also $\frac{dp}{dT} = (nT - m)\frac{p}{T^2}$, whence, by substitution in Clapeyron's equation,

$$L_f = \frac{p(v_l - v_s)(nT_f - m)}{ET_f} = 8\ 23 \text{ cal}$$

Now taking his previously determined value for K, Jouniaux showed that van 't Hoff's expression $K = 0\ 02T^2/L_f$ yielded a value for L_f equal to 8 24 cal, and thus afforded an elegant check on the correctness of his experimental observations.

Having recently found that the molecular depression constant for camphor lies in the neighbourhood of 395 rather than 498, we have examined more closely the above "vérification *a posteriori*" (*sic*), with the following results

Jouniaux's calculation contains several arithmetical errors Using the data chosen by him in this connexion, the values for m, n, and z should be − 362 8, 14 23, and − 80 20 respectively, and not those given above L_f, therefore, on revision becomes 6 33 cal, neither corresponding with the figure $K_{\text{camphor}} = 495$ nor 400, for which L_f should have been 8 24 and 10 2 respectively

The reasons underlying these disagreements would appear to be plain The vapour pressure-temperature measurements utilised by Jouniaux are evidently inaccurate, for, although the Kirchhoff Dupré-Rankine equation is known to apply, with possible errors of about 3 per cent (Juliusburger [13]), to many organic substances, it becomes apparent by taking other sets of vapour pressure-temperature values from the records referred to by Jouniaux that widely different figures for m, n, and z result The following two examples illustrate this

$$(1)\left\{\begin{array}{l} T_1=273^\circ,\ p_1=0\ 06\ \text{mm} \\ T_2=313^\circ,\ p_2=0\ 60\ \text{mm} \\ T_3=353^\circ,\ p_3=9\ 15\ \text{mm} \end{array}\right\} \quad \begin{array}{ccc} m & n & z \\ -3026 & 64\ 85 & -355\ 62 \end{array}$$

$$(2)\left\{\begin{array}{l} T_1=351^\circ,\ p_1=6\ 4\ \text{mm} \\ T_2=404\ 1,\ p_2=75\ 37\ \text{mm} \\ T_3=430,\ p_3=181\ 5\ \text{mm} \end{array}\right\} \quad \begin{array}{ccc} m & n & z \\ -11{,}950 & -14\ 31 & 119\ 78 \end{array}$$

(1) From paper of Allen (loc cit)
(2) From paper of Vanstone (loc cit)

It is therefore obvious that these measurements are not nearly sufficiently reliable to bear the mathematical treatment that Jouniaux attempted to give them In addition, the value he used for the density of liquid camphor was determined many years ago (Kuhara [6]) and relates not to the melting point (178°) but to 205° The density for solid camphor at the melting point is quoted as 0 980 without references, Beilstein gives D_0^0 1 000 D_5^5 0 9998, D_9^9 0 992

In conclusion, it is evident that neither as a verification of his own work nor as a means of discrimination between two values of K_{camphor} so widely different as 400 and 498 are such applications of thermodynamic formulæ of much practical use

Prof Otto Wallach

As a former student of Prof Otto Wallach, I would suggest that the obituary notice in NATURE of April 18 scarcely does justice to the immense services which this distinguished investigator rendered to organic chemistry

Prior to 1880 the utmost confusion existed with regard to the nature of most of the substances contained in essential oils, considerable doubt existed as to the homogeneity of these 'compounds', and very few determinations of structure or synthesis had been carried out Wallach's pioneer work, commenced in 1884, quickly produced important results, and in a few years the original chaos gave place to an orderly and greatly simplified arrangement The distinguishing characteristics of pinene, camphene, limonene, terpinolene, terpinene, and phellandrene were clearly established, and gradually a light was thrown on the inter-relations of most terpene derivatives

Although other workers, notably Armstrong, von Baeyer, Perkin, Semmler, Tiemann, Tilden, and Wagner have made many noteworthy contributions to this branch of chemistry, its present condition must be regarded as largely due to Wallach It is interesting, however, that in the first few pages of his book, "Terpene und Campher", he refers to the valuable work of many of these chemists, including that of Armstrong

It is gratifying to remember that in 1909 Wallach was awarded the honorary doctorate of science of the University of Manchester At that time W H Perkin, junr, was himself directing a flourishing school of terpene research there, and it is probably not inaccurate to regard Wallach's doctorate as a personal compliment paid by one distinguished chemist to another Some years later an important communication on stereochemistry was published simultaneously in *Liebig's Annalen* and the *Journal of the Chemical Society* under the joint names of Perkin, Pope, and Wallach A survey of Wallach's work may, however, be left to the memorial lecture shortly to be delivered before the Chemical Society, and to the exhaustive review of the man and his work which will doubtless be published in the *Berichte* by his German colleagues

Wallach's students will recall the rather short, spare figure of the Herr Geheimrath, his thin grey hair and beard, his keen eyes and intent look as he passed down the centre of the laboratory to his private room, holding with almost painful care some specimen just obtained from one of his students They will remember his optimistic "Geht sehr gut", even when they themselves were by no means satisfied with the progress of the 'Arbeit', or—when a viscous oil persistently refused to solidify—"Immer noch nicht fest? Ruhig bis morgen stehen lassen"

The Geheimrath was always pleased when English students came to work with him, he greatly valued his honorary fellowship of the Chemical Society, and he was frankly pleased at his re-election about two years ago Throughout his tenure of the chair of chemistry in Göttingen, Wallach lived in the old house adjoining the laboratory in Hospitalstrasse with the name 'Friedrich Wohler' in letters of gold over the door He did not understand how a professor could wish to live further from his work than this There in the large room upstairs was kept his fine collection of water colours in which he greatly delighted In 1924 it was my privilege to call upon Wallach, then in the eighth year of his retirement (he retained a room in the laboratory by the courtesy of Prof Windaus, and long after his eightieth birthday he continued to work there) That was the first visit he had received from an English chemist since 1914, and he did not attempt to disguise the pleasure it gave him, and I am happy to think that several letters have passed between us in the last years of his life

Wallach was almost the last of the line of great German chemists—Hofmann, Kekule, Victor Meyer, von Baeyer, Fischer, Wislicenus, Hantzsch—who through rigorous discipline and with infinite patience and diligence built up the structure of modern organic chemistry, and his passing marks the close of a romantic chapter of chemical history

Many chemists in Great Britain who worked with one or other of these giants will remember them with gratitude and admiration They will recall what they owe to their fellow students, to the many admirable features of German university life, and to the knowledge gained and the friendships formed in the mountains and forests of the Harz or Thuringen or South Germany

Pliny's Water-Mill

IN connexion with the letter on "Pliny's Water Mill" in NATURE of June 13, the accompanying photograph (Fig 1), taken by me at Ching chong-do, in Korea, in September 1899, may possibly be of interest It represents a water actuated 'pestle and mortar' commonly used at that time in the hill country of Korea for hulling rice

The apparatus consists of a beam, generally the rough trunk of a tree, about fourteen feet long, to one end of which is attached a wooden box capable of holding water, and to the other end a piece of tree trunk about two to three feet long, fixed at right angles to the beam This last forms the 'pestle' The rice to be treated is in a wooden or stone 'mortar' beneath it

FIG 1—Water actuated pestle for hulling rice at Ching-chong do Korea The bucket is shown in the act of spilling its water

The main beam with its appurtenances is balanced on a trestle so that it is free to move up or down like a 'see saw'

When the box has filled itself with water from the continuous supply furnished through the wooden trough shown above it in the photograph, the pestle at the other end rises above the mortar, and immediately the tipped box empties its water, causing the pestle to drop with a powerful blow on the rice in the mortar The box automatically rises to the filling position again, and the sequence is repeated indefinitely The photograph shows the box in the act of tipping and spilling its water

The straw covered hut in the left background of the photograph contains most of the beam, with the pestle and mortar Its interior was too dark to photograph

H GLENDINNING

Glenalmond,
St Albans, Herts,
June 15

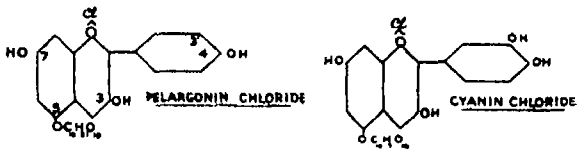
MR H P VOWLES's account in NATURE of June 13, p 889, of the Kashgar water mill is a great help towards the understanding of a hard passage, the difficulty of which is much increased by corruption of Pliny's text ?—For one false reading Mr Vowles's *undershot* water wheel suggests at once the necessary emendation, Rotis etiam quas aqua verset *obiter* et molat ; for *obiter*, hitherto unintelligible, read *subter* I suggest also that in the preceding phrase *rudo pilo* does not at all mean a *roughened* pestle, but is equivalent to *ruente pilo*, and means a *falling* pestle, or drop hammer—precisely what the sense requires We may then translate "In Italy, falling pestles, or drop hammers, are mostly used, and the grinding is moreover carried on by means of wheels, turned by a stream *flowing underneath*" *Pilum Graecum*, which occurs in a Plautine fragment, "quasi tolleno aut pilum Græcum reciproces", seems to have been the technical name for the pair of alternate hammers, working precisely as in the Kashgar mill

A more curious error lurks in the preceding clause The pestle, Pliny tells us, is armed with teeth so that unless the miller keeps a sharp look out while he is grinding (*nisi intenti pisant*), the grain will be cut or chipped (*concidantur grana*), and the iron-work smashed to bits (*ferrumque frangatur*)! It would surely need rough handling to do so Now the grain in question was *far*, or spelt, and we know that our miller was not grinding it to flour or meal, but merely cleaning or husking it for groats, and he had to work carefully and use a light hand lest the grain be chipped or broken, and—*ne farreum frangatur*—lest his *groats* be spoiled

D W T

The Chemical Effect of a Mendelian Factor for Flower Colour

IN 1914, Willstätter isolated the anthocyanin pelargonin from the flowers of the scarlet *Pelargonium zonale*, and stated that a certain violet-red variety contained cyanin, with a trace of pelargonin Recently, Robinson and his collaborators have shown that in both these diglucosidal pigments the sugar residue is probably attached at position 5 on the anthocyanidin molecule If this is so, the only structural difference between these two pigments is the extra hydroxyl group possessed by cyanin at position 3′



These anthocyanins can easily be distinguished by means of the distinct colour reactions given by their crude dilute hydrochloric acid extracts on addition of excess sodium carbonate solution Scarlet red solutions of pelargonin should give an intense violet-red, whilst the cherry red ones of cyanin turn a pure blue Extracts containing both pigments give intermediate colours With the pale coloured flowers, owing to a higher proportion of flavone pigment in the crude extracts, a green colour may be obtained which masks the true reaction and necessitates a preliminary purification The presence of even small amounts of pelargonin can also be detected by the characteristic fluorescence given by this pigment when in acid alcoholic solution

The genetical basis of the formation of these two pigments is being investigated The rose pink variety 'Constance', on selfing by Miss Cranfield, of the John Innes Horticultural Institution, gave seventeen plants resembling the parent and three salmon-pinks, the latter colour being clearly recessive

On testing, the rose-pink flowers were found to contain cyanin, a slight trace of pelargonin, and an appreciable amount of flavone, while the salmon-pinks contained only pelargonin with a trace of flavone

The effect of the factor which converts salmon into rose is, therefore, to substitute cyanin almost

completely for pelargonin, the difference being that of a single oxygen atom

In certain cases in animals a dominant colour factor has been shown to cause the production of a definite oxidising enzyme, and in this case it is not inconceivable that the factor with which we are dealing is in some way concerned in the oxidative processes of the plant

The close connexion between these two anthocyanins in the *Pelargonium* species is further demonstrated by cases of sporting from one pigment to the other

It is interesting to note that these pigments are also found side by side in certain varieties of *Dahlia variabilis*, and that the purple red aster contains both callistephin and asterin, the 3-monoglucosides of pelargonidin and cyanidin respectively

No Mendelian factor has yet come to light which effects a change in the identity of the anthocyanin pigment by means of an alteration in the nature or position of the glucosidal residue, instead of in the superficial structure of the aglucone, and it is the purpose of this note to invite further evidence as to whether this latter alternative may be the general rule

Diamagnetism of Liquid Mixtures

TREW and Spencer [1] have recently reported some very surprising results regarding the magnetic susceptibilities of organic liquid mixtures They find large deviations from the additive law for many pairs of liquids, and in some cases, for example, mixtures of acetone and chloroform, they even claim to find the mixtures to be paramagnetic over a certain range of composition

During the past year I have been engaged in the investigation of magnetic susceptibilities of liquid mixtures, and have developed for the purpose a modification of the Quincke method of capillary ascension which has proved very convenient and accurate in practice Using dark ground illumination, the alterations produced by a strong magnetic field in the level of the liquids contained in two tubes placed side by side between the poles of an electro magnet are photographed under high magnification on the same plate One of the tubes contains benzene, which serves as a standard of comparison, and the other contains the liquid mixture under investigation The plates when measured give results which are reproducible to within one part in a thousand

The results obtained by me do not confirm the work of Trew and Spencer For example, with mixtures of benzene and carbon tetrachloride, for which they report large deviations from the additive relation, I find that the graph connecting susceptibility with composition is a perfect straight line. In the case of mixtures of acetone and chloroform, I find that there is a definite departure from the additive law, which is most pronounced at the concentration at which the density of the mixture shows the largest abnormality But the deviation is very small, being nowhere greater than three per cent of the observed value, and is incomparably smaller than that reported by Trew and Spencer.

From a theoretical point of view, there is reason to expect that molecular association in liquids may influence diamagnetic behaviour to a slight extent, but the results of Trew and Spencer seem wholly outside the range of theoretical possibility It will be noticed that the susceptibilities as measured by them for the pure liquids show large deviations from the accepted values

A Simplified Lecture Demonstration of the Thomson Effect

ELEMENTARY theory represents the Thomson effect as an absorption of heat by a current traversing a temperature gradient in one direction, and an evolution of heat in the other direction In other words, when a current passes over a temperature peak, the originally symmetrical temperature distribution becomes asymmetrical, one side becoming steeper than the other

The converse effect, the production of a potential difference by an asymmetrical temperature distribution, is easily demonstrable Connect a piece of steel wire across the terminals of a sensitive galvanometer and heat to redness any part of the wire by means of a bunsen flame So long as the flame is kept steady there is nothing unusual, but move the flame slowly in one direction along the wire, and the galvanometer gives a decided deflection, which is reversed on reversing the direction of motion of the flame The order of the effect is several microvolts, and can also be shown on a potentiometer Nickel wires also give good results, though copper, of course, conducts too highly

Apparently the motion of the flame produces an asymmetry of the temperature in the wire, a steep gradient where the flame approaches, and a slow gradient behind the flame According to modern statistical theory,[1] the Thomson potential is produced by a temperature gradient, not by a temperature difference, thus, although in this circuit the temperature differences may balance out, there is a greater gradient on one side than the other, and on the balance a potential difference remains

The phenomenon is very much more convenient for demonstration in a lecture than is the more usual method, where the heat absorbed by passing a current along a steep temperature gradient is detected In fact, the whole thing is so simple that I doubt very much whether it has not been noticed before, even though there seems nothing about it in the literature of the subject

Plankton Changes on the Coast of Ecuador

MR G SHEPHERD directs attention in NATURE of April 25 to the masses of yellowish brown plankton matter seen off the coast of Ecuador Some years ago the Chilian coast experienced a similar visitation, with much resulting trouble to locomotive boilers and condensing plant I had some of the water with the brown contents sent home and forwarded for examination to the Marine Biological Laboratory at Plymouth, where it was investigated and the results were kindly communicated to me

A diatom *Grammatophora* (probably *Maina*) was superabundant and was the chief cause of the trouble Other diatoms, *Lyomphora* (sp) and *Thalassiosira* (sp), were also common *Infusorians, Ceratium, Peridinium*, and *Pyzophacus* were frequent

DAVID WILSON-BARKER

Some Notable Women of Science.

By Eng Capt Edgar C Smith, O B E, R N

A CENTURY ago, on June 27, 1831, the eminent French woman mathematician, Sophie Germain, died in Paris at the age of fifty five years, and a few days later was buried in the Père Lachaise cemetery Her great women contemporaries were Mary Somerville (1780–1872) and Caroline Herschel (1750–1848), to whose names might be added, perhaps, that of Mrs Marcet (1769–1858), whose "Conversations on Chemistry" was the means of awaking the interest of Faraday in science Of the careers of Caroline Herschel, the devoted assistant of Sir William Herschel, and of Mrs Somerville, whose "Mechanism of the Heavens" and "The Connexion of the Physical Sciences" gave her a world wide reputation, everyone has heard, but Sophie Germain's story is little known Yet she and Mrs Somerville had much in common, and their minds were cast in the same mould When Mary Somerville, amidst the duties of her London home, was finding time to study the works of Lacroix, Biot, Euler, and Laplace, Sophie Germain was corresponding with Lagrange and Gauss, investigating the motion of the sand on Chladni's vibrating plates, and writing memoirs which gained for her the respect and admiration of both mathematicians and physicists Her place in history is that of the foremost of all French women of science

Mary Somerville, Caroline Herschel, and Sophie Germain were not, however, the first women in modern times to devote themselves to scientific studies Even in the seventeenth century, and amidst the disasters and miseries of the Thirty Years' War, we hear of the German astronomer Maria Cunitz, with the assistance of her husband, compiling new astronomical tables, which, after much delay, were published at Frankfort in 1654. Maria Cunitz died in 1664 To the seventeenth century also belongs the work of Jeanne Dumée, the French authoress of an unpublished memoir on the views of Copernicus, and of Elizabeth Koopmann, the wife of Hevelius, the celebrated astronomer of Dantzig Hevelius died in 1687, but for ten years his wife had been his ablest assistant, and after his death she published the two works, "Prodomus astronomiæ" and "Uranographia, seu firmamentum Sobescianum" Another German astronomer of the seventeenth century, George Eimmart, found in his daughter, Marie Claire, a valuable co-worker, and for him she made some hundreds of drawings of sunspots, comets, and eclipses

Among the women of science of the eighteenth century, one name, that of the Italian mathematician, Maria Gaetana Agnesi (1718–1799), stands out clearly When only eleven years of age she knew eight languages, and in her twentieth year she published a collection of ninety-one theses she had previously defended Her "Instituzioni Analitiche", published in 1748, long continued a valued text-book on the calculus, and is regarded as the first important mathematical work by a woman This work had been preceded in 1740 by the "Institutions de physique" of the remarkable Frenchwoman, Gabrielle-Émilie Chastelet (1706–1749), the friend of Voltaire, and to her we also owe a translation into French of the "Principia" of Newton This was not published until after her death While the names of these two distinguished women belong to the history of mathematics, those of Margarete Winckelmann (1670–1720), the wife of Gottfried Kirch, and of Nicole-Reine Étable de la Brière (1723–1788), the wife of Jean André Lepaute, belong to astronomy Madame Kirch, the wife of one astronomer and the mother of another, while at Berlin discovered a comet and made observations on the Aurora Borealis, and, after she became a widow, she published in 1712 a paper on the approaching conjunction of Jupiter and Saturn Madame Lepaute from an early age had displayed a taste for science, and when at the age of twenty-five years she married the celebrated horologist she at once became his collaborator She was also the friend of Clairaut and Lalande, and assisted them in the calculations on Halley's comet Her own observations are contained in the "Connaissance des temps", 1759–1774 The last years of her life were devoted to her husband, who was struck down with sickness, and she died at Saint Cloud a few months before him. Another woman of science of the eighteenth century was Dorothea Erxleben (1715–1762), who in 1742 published a work on the cultivation of science by women, and in 1754 was made a doctor by the University of Halle

Though to-day women are found working at every branch of science, it has been mainly in the realm of astronomy they have hitherto done their most notable work Following in the footsteps of Mary Somerville and Caroline Herschel, during the nineteenth century a succession of women made their mark either as observers or as writers on astronomy Maria Mitchell (1818–1889) was long the professor of astronomy and director of the observatory at Vassar College in the United States She was provided by the women of America with a large equatorial, and the observatory at Nantucket, now under the direction of Miss Margaret Harwood, was erected in her honour. Two other American women, Anna Winlock, who died in 1904 and Mrs Williamina Fleming (1857–1911), were connected with Harvard University Especially important were the writings of Miss Agnes Mary Clerke, who was born in County Cork in 1842 and died in London in 1907 Her sound judgment and her wide acquaintance with astronomical literature made her "History of Astronomy during the 19th Century" a most valuable book of reference This work first appeared in 1885, and was followed by her "System of the Stars", 1890, and "Problems in Astrophysics", 1903 Her most eminent woman contemporary in England was Margaret Murray, who in 1875 married Sir William

Huggins Like Caroline Herschel, Mary Somerville, Anne Sheepshanks, Miss Clerke, and Mrs Fleming, Lady Huggins enjoyed the distinction of being elected an honorary member of the Royal Astronomical Society

In other branches of science, mention may be made of the Russian mathematician, Sophie Kovalevsky (1850–1891), who studied under Weierstrass at Berlin, and in 1884 was made professor of higher mathematics in the University of Stockholm, Mrs Ayrton, the first woman member of the Institution of Electrical Engineers, and who was proposed for admission into the Royal Society, Marie Sklodowska, better known as Madame Curie, famous for all time as the discoverer of radium; and Dorothea Klumpke, who in 1893 was the first woman to obtain the doctor's degree in the mathematical sciences at the Sorbonne Her thesis was a study of the rings of Saturn It was when granting her the degree that M Darboux said that her work gave her a place beside Maria Agnesi, Sophie Kovalevsky, and Sophie Germain To this short sketch of some women of science other names might be added, but from what has been said it will be seen that France, England, Switzerland, Russia, Italy, Germany, and America are all represented, showing that the women of science, like science itself, have been confined to no one country or age

Diet and the Teeth *

AS a result of numerous experiments, Mrs Mellanby has shown that there is an intimate relationship between the structure of the teeth in dogs and the composition of the diet, more especially its vitamin D content (see NATURE, vol 125, p 604, 1930) In further work she has now demonstrated a relation between diet and the structure of the teeth in rabbits and rats, as well as one between diet and certain forms of dental disease in dogs and other animals

Defects of structure similar to those observed in the teeth of imperfectly fed dogs are common in other animals and have been found in horses, monkeys, rabbits, and ferrets A common defect is the presence of interglobular spaces in the dentine in fact, these spaces are so common that it is only their absence from teeth with smooth white enamel and their presence in large numbers in obviously imperfectly calcified teeth that has enabled one to say that they are abnormal structures and that their presence in a tooth otherwise well calcified indicates a certain degree of imperfect development or hypoplasia

The dentition of rabbits and rats differs considerably from that of the dog in the former, the permanent dentition shows continuous growth throughout life, in the latter, there is no temporary dentition, and the incisors grow from persistent pulps as in the rabbit, but the molars cease growing after eruption, as in dogs Young rabbits, about eight weeks old, were used for the experiments they were placed on a diet containing four parts of oats to one part of bran with 1 5 per cent calcium carbonate, 6 c c decitrated lemon juice were also given daily Without the latter, the animals developed scurvy, and without the calcium carbonate, good growth and health were not maintained The condition of the teeth on this basal diet was worse than when the calcium carbonate was omitted, since growth was better Except when vegetables were included, it was necessary to supply water also

The defects produced by this diet were as follows the enamel was thin and irregular and stained deeply with carmine, the dentine was thin and easily stained and contained many interglobular spaces, the odontogenetic zone was wide and irregular the jawbone was poorly calcified, consisting largely of osteoid tissue or osteoporotic bone

The addition to the diet of materials rich in vitamin D, such as cod liver oil, egg yolk, and irradiated ergosterol, induced good calcification of the teeth the two former, however, were not well-borne, death following after 7-8 weeks Smaller doses of cod liver oil, for example, 0 5 c c instead of 1-2 c c daily, with a supplement of 20 gm or more of cabbage, markedly improved general health and growth, and calcification was excellent Vegetables alone exerted only a small calcifying effect, although improving general health dandelion and clover were fairly effective, cabbage had little influence unless fed in large quantities, the allowance of oats and bran being at the same time reduced summer but not winter grass, was comparable to cabbage Swede-turnip, carrot, potato, and white turnip had little or no calcifying power As might be expected, irradiation of the animals with the mercury vapour lamp also improved the structure of the teeth

The amount of calcium and phosphorus in the diet and the calcium/phosphorus ratio are only of importance when the vitamin D intake is low In the basal diet, the ratio is 1 0 81 and the actual percentages of these elements relatively high It is of interest to note that rats fed on similar quantities of calcium and phosphorus have normally calcified bones When the calcium carbonate was replaced by phosphate the rabbits grew as well, but the calcification was much improved

The experiments on rats indicated that the defects of structure caused by a deficient intake of vitamin D were very similar to those found in rabbits, and that supplying this factor in the diet resulted in the development of perfect teeth

Although it has not been found possible to produce caries satisfactorily in the teeth of experimental animals, it has been shown that the development of the periodontal tissues in dogs and their subsequent liability to disease can be controlled by the diet. On a perfect diet the gingival region of the jaw is comparatively thin the subgingival epithelium is

* Medical Research Council Special Report Series, No 153 Diet and the Teeth an Experimental Study Part 2 A Diet and Dental Disease, B, Diet and Dental Structure in Mammals other than the Dog By May Mellanby Pp 94+28 plates (London H M Stationery Office, 1931) 2s 6d net

thin and regular and the corium is composed of connective tissue only The alveolar bone is compact On a diet deficient in vitamins A and D the gingival region is thick, the epithelium is hypertrophied and finger-like processes extend down into the corium, in which varying degrees of cell infiltration are present the alveolar bone is poorly calcified and consists in part of osteoid tissue Experiments proved conclusively that, whereas vitamin D controls the calcification of the jawbone, vitamin A is responsible for the perfect development of the soft tissues The gingival epithelium is thus comparable to epithelia in other regions which are abnormally developed in the absence of vitamin A The distinction between the effects of the two vitamins was clearly seen when vitamin A was supplied to one animal as mammalian liver oil (which contains no vitamin D) and vitamin D to its litter mate as irradiated ergosterol

Periodontal disease does not develop when the animals are fed on a diet containing abundant fat soluble vitamins, even though it is soft and pappy throughout life For prevention it is essential that the puppy be fed on a good diet for the first months after weaning if the intake of vitamins A and D is low at this period, a certain amount of disease almost invariably develops even although the diet is good for the rest of life When the tissues are properly developed owing to an adequate vitamin intake, very considerable resistance to disease is shown in later life even though the diet is incomplete for long periods After the disease has once appeared, further progress can be arrested by administration of large amounts of vitamins A and D, but a complete cure was not observed It may be concluded that diet acts primarily by controlling the developmental structure of the periodontal tissues and not by any direct or indirect effects concerned with bacterial decomposition in the mouth Prevention appears to be all-important once the tissues have developed abnormally, prevention of disease becomes extremely difficult

Caries has been observed only occasionally in the teeth of dogs, rabbits, rats, and monkeys, and attempts at its experimental production have usually failed Even when micro-organisms were fed for a long period, they were rarely found in the teeth In rabbits, however, softening of the exposed dentine on the occlusional surface of the molars was fairly frequent, especially when the animal had been fed on a defective diet, and organisms were found in the dentinal tubules in the majority of such teeth

When an erupted tooth is attacked by disease or suffers injury, it reacts by the production of secondary dentine Mrs Mellanby has shown that the structure of this new dentine, both in dogs and rats, depends on the amount of vitamin D in the diet, in the same way as that of the primary dentine The reaction only occurs in a living tooth As secondary dentine was not always found when the teeth were worn down by natural attrition, its production was stimulated artificially by filing the teeth and extracting them after this treatment had been carried out for six weeks It was found that perfect dentine was laid down when there was abundant vitamin D in the diet, that oatmeal interfered with the action of the vitamin, and that when the diet contained little, little or no secondary dentine, or dentine with many inter globular spaces, was produced

This experimental study has indicated certain lines of investigation in the problem of the arrest and prevention of caries in human beings, the conclusions reached will be described in Part 3 of this series

---

Magnetographs obtained by Amundsen, 1903–1906 *

WHEN Captain Roald Amundsen started his voyage in the *Gjoa* through the North-west Passage in 1903, his first aim was the accomplishment of this great feat of exploration, and his second was the investigation of the magnetic conditions at and near the magnetic pole After his return from these successful enterprises, he published an account of his voyage, "The North-west Passage", in 1907, but his scientific material for a long time lay stored in the Historical Museum, pending its publication by a board of editors State grants were made at various intervals between 1908 and 1923 towards the preparation and publication of the results, and the preparation of the terrestrial magnetic data was finished in 1923, at that time further funds for the publication became difficult to obtain, but by restricting the scale of the work the funds were finally obtained for publication by the Geophysical Commission of the Norwegian Academy of Science at Oslo in its regular volumes. Part 1 is to deal with astronomy and meteorology, and Parts 2 and 3 with terrestrial magnetism The first to appear is Part 3, which consists of a repro duction of all the magnetographs obtained by the expedition, with only sufficient text (17 pages) to explain their nature It is "assumed that in some way or another funds will be obtained for the publication of Parts 1 and 2"—an assumption which geophysicists will earnestly hope to see confirmed

Amundsen occupied Gjoahavn on King William's Land (68° 37′ N, 95° 53′ W) from Sept 12, 1903, to Aug 13, 1905, and King Point on the coast of Alaska (69° 6′ N, 138° 8′ W) from Sept 3, 1905, to July 11, 1906 At Gjoahavn the variometer house was constructed out of the packing-cases of the expedition (specially prepared free from iron for this purpose) and the instruments were set up by Oct 31, 1903, and continued working until June 1, 1905, at King Point the dates were Oct 17, 1905, to Mar 31, 1906, the variometer house there being constructed of drift timber. The houses at both places were partly dug into the ground, and covered over with sand; even so, the temperature inside them underwent great changes, at Gjoahavn from

* Geofysiske Publikasjoner, vol 8, pp 17+191 plates (Oslo, 1930.) 20 00 kr.

5° C in summer to −26° C in winter, with a daily range of about 1° C, at King Point they were still greater, the daily range being 6° or 7° C. Unfortunately, the registering instruments were not well compensated for temperature.

The data have been prepared under the editorship of Nils Russeltvedt and Aage Graarud, and the difficulty of their task must have been very considerable, in inferring temperature coefficients, base line values (frequently altered), and scale values. In stating the latter, they do not indicate in what unit the ordinates are measured, but it appears to be 1 mm. The scale values (per mm.) of the three instruments, which were of Eschenhagen pattern, all registering on one drum, were for declination (in force units) 17γ, in horizontal force 12γ, and for vertical force 5γ until about September 1904, and thereafter 22γ; at King Point the corresponding values were about 20γ, 12γ, and 23γ. In the vertical force record, 1° change of temperature made an apparent change of 140γ in the force. The normal time scale was 20 mm. per hour; in quick runs it was twelve times as great.

The magnetographs show records and base lines for the three magnetic elements and for the temperature. Before reproduction the times were marked on the hour lines automatically registered across the sheets, the date was written on, and the various traces were indicated by letters at one end. It is to be regretted that on sheets which show disturbance, when some of the traces often crossed one another, the letters were not added elsewhere also; in the reproductions it is often not easy to be sure of the identity of each trace on such days, while on the originals the difficulty is likely to have been much less.

The sheets are reduced on reproduction in the ratio 3·46 to 1, so that four can be got on to a quarto page; the reproduction is very good, and the collection should be of great value to those who wish to make intercomparisons between the changes of the earth's field near the auroral zone and elsewhere. The curves indicate the presence from time to time, in the neighbourhood of these stations, of intense overhead currents, usually somewhat to the south, and sometimes flowing eastwards, at others westwards. This would suggest that both stations are within the auroral zones, and it will be of interest to learn later, from Part 1 or 2, whether auroræ usually appeared to the south.

The magnetic results of the Amundsen expedition would have been of still greater value had they coincided in time with Birkeland's magnetic and auroral expeditions of 1902–3, the results of which were published by him in 1908 and 1913. Though this was unfortunately not so, their value will enhance, and be enhanced by, Birkeland's data, and they will form an important link in the chain of evidence which will lead to the elucidation of the very difficult problems presented by magnetic disturbance.

Obituary.

MR. C. T. HEYCOCK, F.R.S.

THE death of Mr. Charles Thomas Heycock, on June 3, removes from among us one who had gained the affection of generations of Cambridge men and who was a pioneer in an important branch of inorganic chemistry. Heycock was the younger son of Frederick Heycock of Braunstone, Oakham, and was born on August 21, 1858; he received his early education at the Grammar Schools of Bedford and Oakham, and entered King's College, Cambridge, as an exhibitioner in 1877, taking the Natural Sciences Tripos in 1880. For many years he taught chemistry, physics, and mineralogy for the Cambridge examinations, and in 1895 he was elected to a fellowship at King's College, becoming a college lecturer and natural sciences tutor in the following year. He was elected a fellow of the Royal Society in 1895, and was awarded the Davy Medal in 1920 for his work on alloys. His original work on the metals attracted the attention of the Goldsmiths' Company, who endowed a readership in metallurgy at Cambridge; he was appointed to this office in 1908 and held it until his retirement in 1928. He was admitted to the Livery of the Goldsmiths' Company in 1909 and to the Court in 1913; he acted as Prime Warden during the year 1922–1923, and took a keen interest in the work of the Company's Assay Office.

Notwithstanding the exacting character of his work as a Cambridge coach, Heycock joined with his lifelong friend, F. H. Neville, in a comprehensive study of the metals and their alloys; this partnership, which was only dissolved by the death of Neville in 1915, led to a remarkable series of papers in which novel directions of investigation were mapped out and developed. The first of these joint papers was published in 1889 and dealt with the depression of the freezing points of metals brought about by others dissolved therein; in this and later papers it was shown that the addition of small amounts of a second metal depresses the freezing point of the first to an extent (1) directly proportionate to the weight of metal added and (2) inversely proportionate to the atomic or molecular weight of the added metal. Raoult's law for ordinary solutions was thus extended to alloys, and a method indicated for calculating the latent heat of fusion of a metal by the application to the freezing point depressions of the now well-known van't Hoff equation. At the outset, mercury thermometers were used in the temperature measurements and only alloys of low melting points could be studied; the introduction by H. L. Callendar of the platinum resistance pyrometer made it possible to extend the scope of the investigation to metals of high melting point. This was done with the assistance of Dr. E. H. Griffiths. During the carrying out of the programme thus extended, the melting points of many of the metals in the pure state were determined; later observers have confirmed the

substantial accuracy of most of the melting points given by Heycock and Neville

The study of the melting points of dilute solutions of one metal in another led naturally to the determination of the melting points of mixtures of metals in all proportions, a technique was developed by which the results, interpreted by means of the phase rules of Willard Gibbs and Roozeboom, were supplemented by the microscopic examination and photography of polished and etched sections of the solidified alloys The most detailed piece of work done on these lines was that on the copper-tin alloys, which formed the subject of the Bakerian Lecture before the Royal Society in 1903, the two collaborators also made a minute study of many other binary and ternary alloys They had already shown in 1897 that X ray photographs of thin sections of alloys could provide valuable information as to the physical state of the component metals

The major part of Heycock and Neville's experimental work was carried out in a small laboratory in Sidney Sussex College and, owing to the many other duties which fell upon the two partners, much of it had to be done late at night and in the early hours of the morning It may seem surprising that such a quantity of data of enduring value could be collected under such conditions but both men were enthusiasts, both possessed an exquisite sense of technique, and both were meticulous in their striving after accuracy

Heycock was an excellent lecturer, his whimsical mode of addressing a class sustained an interest in inorganic chemistry during a period when that subject seemed in danger of eclipse by the rapid advance of organic chemistry He had few equals as a teacher in the laboratory, his deliberate method of working and his sarcastic denunciation of slovenliness inspired respect and awakened the spirit of emulation Much of the work of organising and planning the numerous extensions of the University chemical laboratories during the last twenty-five years fell upon him, and he carried it out with characteristic care and thoroughness His physical vigour found further expression in his devotion to the Volunteer movement from quite early days, and during the War he was appointed Lieutenant-Colonel of the Cambridgeshire Regiment

In his domestic life, Heycock was thoroughly happy, his house was the meeting place of undergraduates and seniors alike, and its cheerful hospitality is a delightful remembrance to vast numbers With his death we have lost a scientific man of the old type who would spare no pains or time in eliminating error from an experimental observation, many of us have also lost a shrewd and wise counsellor and one of the most staunch and loyal of friends W J POPE

DR A T MACCONKEY

DR ALFRED THEODORE MACCONKEY who died on May 17 at the age of seventy years, was known to bacteriologists in all parts of the world as the originator of the medium which bears his name After taking his medical degrees in 1889, he settled in practice for some years, but relinquished it in consequence of an illness, and decided to devote himself to research work in bacteriology

MacConkey was associated for a time with Washbourn and Eyre in the laboratories of Guy's Hospital, his old school, and afterwards with Boyce in the Thompson-Yates laboratories in Liverpool His appointment about this time as assistant bacteriologist to the Royal Commission on Sewage Disposal, the working headquarters of which were at Leeds, determined the trend of his researches during the early years of the century The problems that called for solution fascinated him, and his interests were soon deeply engaged in the technical part of the work. During the period 1900–9, he published a number of papers, which embody his pioneer studies upon the classification of the lactose-fermenting bacteria of intestinal origin, and upon the differential criteria of this group and their significance as contaminants of water, milk, and foodstuffs

The introduction of MacConkey's bile-salt medium put into the hands of bacteriologists a simple and effective tool for the separation of the typhoid-dysentery group of bacilli Bile-salts had been added to media so early as 1889, and MacConkey's first experiments with them were made in 1897, in 1900 he was using bile-salt lactose agar for the purpose of isolating *B typhosus* and *B coli communis* In 1902, Grünbaum and Hume suggested the addition of neutral red as a colour indicator for colonies that either do or do not ferment lactose, and MacConkey adopted this improvement in the method He was one of the first to appreciate the importance of noting and comparing the biochemical activities of the intestinal group of bacilli with the object of defining their specific characters and their relationships Thus, he based a useful classification of the coliform group upon the ability of its members to ferment saccharose and dulcitol

In November 1901, MacConkey joined the staff of the Lister Institute, London, as an assistant in the bacteriological department His transference soon afterwards to the serum department of the Institute at Elstree, then under the charge of the late Prof George Dean, directed his energies to the solution of the problems which surround the preparation of toxins and antitoxins In April 1906, he became the head of the department, and he remained at Elstree until his retirement in April 1926, at the age of sixty-five years He continued the early work of his colleague, Dr J C G Ledingham, on serum concentration, and developed the technical processes for refining and concentrating antitoxic sera There are workers in many countries who owe their practical knowledge of the subject to the information which MacConkey freely put at their disposal In 1912 he contributed to the reports of the Plague Research Commission in India an interesting paper on the production and titration of anti-plague serum, in which he showed that the specific antitoxin can be concentrated by the usual methods, and that it is associated with the

pseudo-globulin fraction of the serum proteins He had previously made a comparative study of the antigenic relationships of the plague bacillus and the pseudo-tubercle bacillus and was able to confirm the close kinship of these bacteria, as judged by the results of precipitin and immunity tests

In 1912, MacConkey published a remarkable paper which indicated a seasonal change in the potency of diphtheria toxin when produced in regular weekly batches His curves certainly seem to show a significant increase of toxicity during the winter months as compared with the level attained in the summer Moreover, he directed attention to the close correspondence of the toxin curve with that of the prevalence of diphtheria in London and elsewhere These observations are unique, and the present writer is disposed to believe that they are related to variations in the health and susceptibility to infection of the stock of guinea-pigs from which the test animals were drawn

During the years of the War, MacConkey put his energies without stint into the task of enlarging and organising his department to meet the increasing demands made upon it by the army authorities for tetanus antitoxin, antidysentery serum, and antimeningococcus serum He took a keen interest in the prophylaxis and treatment of tetanus by means of antitoxin, and he published several papers on the subject , in some of them he reviewed the observations of workers in many countries, and in others he gave an account of experimental work carried out by himself and his colleagues He served as a member of the War Office Committee for the investigation of tetanus In his published articles he put forward a strong plea for devoting special attention to the early signs and symptoms of tetanus, on the ground that the antitoxin is likely to influence the disease only when administered as soon as the symptoms are recognisable The limited response to his appeal and the scanty information which came to hand disappointed him, but it is probable that he had not sufficiently appreciated the difficulty of discriminating between the premonitory subjective symptoms of tetanus and those which were attributable to sepsis and to the nervous strain from which the patients were suffering

MacConkey, as the writer has good reason to know, was essentially a man of a kindly disposition His sense of duty was so strong that, during the trying years of the War, he suffered from the strain to an extent which weakened his resistance and laid the foundation of a cardiac disability from which he never really recovered G F P

MR E TORDAY

THE death, at the age of fifty-six years, of Emil Torday, which occurred on May 9, at his London home, removes one of the most distinguished of African ethnologists A Hungarian, his adventurous spirit led him to the heart of the Dark Continent some thirty years ago He there acquired a great affection for its savage native inhabitants, and by his personality inspired in them an equal affection for himself

Deeply interested in native manners and customs, Torday made these his life's study To this end his wonderful linguistic talents helped very considerably He spoke seven European languages and eight of the tongues of Central Africa His works on the ethnography of the Negro, written in collaboration with Capt T A Joyce of the British Museum and published by the Belgian Government in French, " Les Bushongo " and " Peuplades de la forêt et Peuplades des prairies ", are surely models to be followed by future students of native life In lighter vein, but scarcely less informative to the general reader, is his " Causeries congolaises ", published in Brussels in 1925 In English he published " On the Trail of the Bushongo " and " Camp and Tramp in African Wilds ", besides contributing numerous articles and reviews on African ethnology to the *Journal of the Royal Anthropological Institute*, *Man*, and *Africa* Only just before his death he had completed his monumental volume on " African Races " for the series of works upon descriptive sociology founded by Herbert Spencer, which was reviewed in NATURE of May 2, p 655

Of Torday's personal courage a word must be said Upon one occasion he stepped in between a party of defenceless children and the warriors of a hostile tribe who had their bows already drawn to annihilate the children of their national enemies Torday, unarmed, stepped in between the warriors and their victims, and, by his utter disregard of personal safety, saved the lives of innocents and the commencement of an inter-tribal feud which would probably have lasted to this day

The loss of Torday, could it be made known to them, would most certainly be regretted by many tribes in Central Africa It will as certainly be regretted by scientific workers in Europe One who was privileged to accompany him for two years upon his last great Central African journey mourns his loss not least of all

M W HILTON SIMPSON

MR TORDAY'S contribution to the science of African ethnology was twofold His publications have already been mentioned , they constitute a record of the highest importance But he was also distinguished as a practical field worker , and the ethnographical collections from the Belgian Congo, all carefully documented, with which he enriched the British Museum between 1907 and 1910, are of outstanding excellence Both in quantity and quality they are unrivalled among our African collections and it is not too much to say that the study of them is essential for anyone who would understand the high level of refinement in decorative and textile arts of which the Bantu are capable In performing this signal service to the nation, Torday has incidentally achieved a fitting memorial to himself and his labours, which will increase in value with the passage of time He worked for some years in an unofficial capacity at the British

Museum, arranging and labelling his own and other collections, and his deep knowledge of African matters was always placed freely at the disposal of the staff

Mr Torday was also one of the most active members of the Royal Anthropological Institute, attending its Council meetings regularly, helping in the improvement of the library, reading papers, and rendering invaluable and unselfish service in a variety of ways In 1929 the Institute awarded him the Rivers Memorial Medal for anthropological work in the field Torday was also a Chevalier of the Order of the Crown of Belgium, and by his own country he was awarded the Great Gold Medal for Literature and Science, a rare distinction

By his death African ethnology loses one of its most brilliant, sincere, and devoted students, and his friends the privilege of a delightful and stimulating personality H J Braunholtz

News and Views.

It was a remark of Lord Oxford's, that the business of biography is the vivid delineation of a person, and that for its success one of its obvious conditions is that the person delineated should have the power of permanently interesting his fellow men Of all men of science, Faraday assuredly was such a person, his rare mental qualities, combined with a singularly refined moral nature, making him as worthy a subject for the biographer as a Pasteur or a Lister Some of the characteristics of Faraday were admirably brought out by Dr R L Mond, who on June 11 delivered the Second Spiers Memorial Lecture to the Faraday Society Referring to the approaching celebrations of the centenary "of one of the most fruitful conceptions of the human mind", Faraday's discovery of electro magnetic induction, he said many, well qualified, will comment on the origin of this conception, its development and application, but there is one aspect of this triumph of the human mind which deserves special consideration, namely, the study of the conditions and of their influence on the individuality which makes the conception a possibility This naturally led Dr Mond to refer to Faraday's early environment One dominating influence was his association with the Sandemanian form of belief, which combines (like that of the Quakers and Unitarians) a great simplicity of mind with exemplary conduct and love and esteem for your fellow members Next came the influence of books, the writings of Bacon, of Dr Watts, of articles in the Encyclopædia Britannica, and of Mrs Marcet's book on chemistry Faraday also found both assistance and inspiration by his association with the ardent spirits of the City Philosophical Society, and then came the turning point in his career when he was engaged by Davy, a step which in turn led to his memorable tour on the Continent, "a high school of incomparable value"

"But", said Dr Mond, "what can we learn from Faraday's career, that we can usefully apply both to the search for new knowledge, the Perfection of what we all possess, and the Perfectibility of those who are devoting themselves to this research?" This question led to the examination of Faraday's views on education Giving evidence before the Public School Commission in 1862, Faraday said, "I do think that the study of natural science is so glorious a school for the mind that, with the laws impressed on all these things by the Creator, and the wonderful unity and stability of matter, and the forces of matter, there cannot be a better school for the education of the mind" Reverence for the beauties of Nature and the laws which control them, in Faraday was combined with a reverence for great thinkers and the truths they were unfolding One of the problems of to day is how to guide the footsteps of those whom we hope will emulate our great prototype, and the task often is "how to bring the great pupil to the great teacher" Modern civilisation has evolved an intellectual machine which, from heterogeneous raw materials, attempts to produce a uniform product, but we shall have to provide opportunities where the young mind can develop, untrammelled by any hard and fast system, under the ægis of a wise and kind direction, and where every suitable aid to self development and facilities for scientific research are amply provided

The English Channel was crossed for the first time by a British built glider with a British pilot, Mr Lissant Beardmore, on June 19 The pilot, having been towed by an aeroplane to a height of about 14,000 ft above Lympne, at 4 30 p m released his machine and glided in a continuously falling path, landing at St Inglevert aerodrome just after 6 p m It is unfortunate that he will not be officially recognised as being the first person to glide the Channel, since he was prevented from applying to the British Gliding Association for the proper observation of his performance by the anomaly that he did not hold the most advanced of the certificates awarded to glider pilots, and was therefore not judged competent to undertake the feat Herr Kronfeld, on a German-built machine, accomplished the same flight, in a similar manner, under official observation, on June 20 He flew from France to England, and thus becomes the holder of the official distinction He afterwards made a return glide from Dover to St Inglevert, being again raised to the required height by an aeroplane that had accompanied him, and qualified for the *Daily Mail* prize for the first glide across the Channel in both directions on the same day

The executive committee of the Committee on Intellectual Co operation of the League of Nations at its April meeting considered a request from the Chinese Government for co operation with the League organisations in the intellectual and scientific field The principal suggestion related to the exchange of university professors The Chinese Government proposed to send to Europe students, writers, philosophers, historians, and archæologists, and invited the League to organise tours in China for specialists in medical,

political and natural science, and legal questions A request was also made for professors of geography and geology for the University of Nanking, particularly of English, Austrian, Scandinavian, or Swiss nationality, who could give instruction in English A further request for co operation considered at the same executive committee meeting related to the better utilisation of leisure—a problem which is assuming ever greater importance as a result both of the reduction in hours of work and of the tendency to mechanisation and specialisation of labour The request was received from the International Labour Office, and the Committee authorised the director of the Institute to accept the offer of the International Labour Office and assist in the study of the conditions of popular arts and public libraries in various countries, their resources, and accessibility to the workers, by collecting complete information on these subjects in relation to the problem of workers' leisure as a basis for comparison, conclusions, and appropriate action

SINCE the old days of driving sheep from the Argentine to the southern sheep stations of Patagonia, no drive can compare, for duration and extent, with the reindeer movement now in progress in Canada In 1929, 3000 reindeer were purchased in Alaska by the Canadian Department of the Interior, and in December of that year the work of herding the animals from the west coast of Alaska to the eastern side of the Mackenzie River was begun In the spring of 1930, the herd had reached the Hunt River in the Kotzebue Sound area, where a halt was made for the fawning season During the summer the herd, with its 2000 fawns, remained in this region, until the second stage of the drive began late in 1930 The movement was then continued in a north easterly direction toward the pass leading to the Colville River It was reckoned that the second fawning season on this long trek would be passed in the delta of that river, so that probably only about 400 miles now separate the herd from its new range to the east of the Mackenzie delta Here it is expected to arrive during the winter of 1931–32

THE *Quarterly Bulletin* of the Imperial Bureau of Animal Genetics, vol 2, No 2, just issued, contains a useful summary of recent developments in fur production and reindeer breeding Since the first fox farms were established in Prince Edward Island, this industry has grown largely in Canada, and attempts, not very successful, have been made to domesticate other species Questions of fur production from many animals are discussed, and it is pointed out that the most important fur bearer in the world is the rabbit, because it breeds rapidly and well in captivity and can be produced genetically in a great variety of colours The reports of the Porsild brothers on the possibilities of reindeer breeding in Arctic Canada and the problems of reindeer husbandry are considered at some length The Mackenzie delta and Great Bear Lake regions are found to be capable of supporting large herds, hence the reindeer movement Experiments are already being made in crossing the reindeer with the large woodland caribou of Newfoundland Other items in this bulletin are a list of literature on reindeer, reviews of books on fur farming and rabbit breeding, and notes on the domestication of mink A bibliography on fur breeding will shortly be ready and obtainable from the Bureau in Edinburgh for 1*s* One on the biology of the fleece has already been published at 2*s* 6*d*, and another on the genetics of the rabbit is in preparation

GERMAN oilfield developments have been prominent in the press lately, consequent on the Royal Dutch Shell Company's active interest in the operations, of which a report appeared in the *Times* of May 22 For some time past, both German and American companies have been engaged on exploratory work, but the results have scarcely justified the claims originally made as to resources, though there would seem to be evidence of petroleum occurrence over a wide area in the north-west From a technical point of view, one of the best recent accounts of the fields is given by Von E Krenkel in the April number of *Die Naturwissenschaften* For all practical purposes, the chief developments have been in the Hanover region within a radius of some fifty kilometres from that city, and the features of geologic interest are the Zechstein salt bodies This region includes the Oelheim, Hänigsen and Wietze fields among others, from which there has been a steady though not spectacular production, the prospective total for this year for the region as a whole is estimated at 200,000 tons Unproved areas lie to the north (Oldenburg) and elsewhere in the Hanover province, already noted for the famous Limmer and Vorwohle rock asphalt deposits It is clear that although comparable salt structures with those of certain other oilfields are known in this part of Germany, they are not, in the present state of our knowledge, significant of the existence of oilpools of magnitude

A LARGE proportion of the current issue of *Africa* (vol 4, pt 2) is devoted to the consideration of matters of practical import Instructions for missionaries who have opportunities for extended ethnographical observation, which have been prepared by Dr Westermann, and suggestions for the teaching of hygiene to women, by Miss Mary Blacklock, have a grasp of the problems in their respective fields which gives them a claim to careful consideration There are, however, two other communications which call for more than passing mention, as illustrating the principles, recently discussed by Prof Malinowski and others in the pages of *Africa*, which bear on the value of scientific study of native institutions in relation to practical problems It was urged that in a changing Africa neither an academic nor an antiquarian interpretation of the field of inquiry is likely to have any practical effect, but that what is needed is a study of the functioning of existing institutions as integral parts of a culture considered as a whole

IN the first of the two communications to which we refer, Mrs A W Hoernle, in considering the native conception of education in Africa, points out the

significance of age and sex in determining occupation, the function of the family as a social unit, and the place of initiation in ensuring tribal continuity of tradition through the instruction given in the initiation schools, and discusses the bearing of these factors upon the problem of educating the native in present conditions Mr D S Knak, in his study of the influence of European civilisation on African family life, deals with native marriage on similar lines, referring particularly to native as opposed to European forms in marriage and the difficult problem of polygamy The two papers may be commended to the attention of those who are prepared to consider impartially the respective claims of the scientific student and of the 'man on the spot' with practical experience but unbacked by specialist knowledge, to speak with authority on native problems which call for solution both now and in the immediate future

IN his presidential address to the Devonshire Association on June 23, the Bishop of Plymouth gave an admirable, but necessarily brief, survey of the history of religious houses in Devonshire Unfortunately, Devonshire had no chronicler in its monasteries to emulate, even *longo intervallo*, Jocelin of Brakelond, and, as Dr Masterman was constrained to admit, the actual history of most Devonshire religious houses has passed into oblivion Yet for five centuries they played a large part in the religious and social world of Devonshire, if we may judge from the contemporary evidence of a writer whom the Bishop quoted, even though he dealt with another county It would appear that the monks dealt paternally with their tenants, if less efficiently than the landlords who succeeded them, and it is significant that among the demands of the Cornish and Devon rebels of 1549 one was that two of the chief abbeys in each county should be re established At the time of their abolition, the number of religious houses in Devonshire ranked sixth among the English counties, ten being included among the greater monasteries, that is, monasteries of which the income exceeded £200 (about £3000 in modern currency) The suppression seems to have been carried out by peaceful negotiation In nearly every case the abbot and his brethren received pensions Of Devonian monasticism one relic remains in 'the Abbot's Way', the rough track across Dartmoor which once linked Buckfast and Plympton with Buckland and Tavistock, marked by broken crosses set up to guard the traveller from the pixies that haunt the moor

THE advantage of short over long wave transmission for broadcasting is that it is much less affected by atmospherics and fading In some parts of the world, for example, in Central and South America, these causes prevent reception of long wave stations sometimes for months at a time This probably accounts for the great popularity of short wave broadcasting in America At present, according to *World Radio* for June 12, there are thirty-seven firms engaged in the manufacture of short wave receivers. These receivers range from the one valve to the thirteen valve set Home-built sets are almost a thing of the past, manufacturers are now competing with one another and the prices are very reasonable Combination receivers which allow the listener to tune in at all wave lengths between 14 and 550, the latter being the upper limit of the American broadcast band, are the most popular At present there are twelve operating short wave broadcasting stations in the United States and a few in Canada and Mexico All relay musical programmes and can be heard in the United States Distant reception is also to be had from all parts of the world The Rome station on 25 4 metres is heard best in the eastern portion of the country, and the station at Saigon, in French Indo China, in the western section It is noticed that the Rome station does not fade so early in the evening as stations farther north Many new stations are being built, broadcasting on short wave lengths only

IT is interesting to notice that when the London United Tramways were faced with the necessity of a heavy expenditure in connexion with their tram track and vehicles, for about seventeen miles of their tramway system in Surrey they decided to adopt trolley bus working The first trolley bus service in London started on May 16 and has given satisfaction This type of transport is common in many towns both in Great Britain and abroad, and the number of trolley buses in operation is increasing very rapidly In the *English Electric Journal* for June an account is given of various types of 'English Electric' trolley buses They run smoothly and quietly, and are capable of rapid acceleration and powerful braking When fully loaded they are capable of a speed of about thirty miles per hour on the level and eighteen miles per hour on a five per cent gradient The maximum operating acceleration is three feet per second per second, which allows twenty miles per hour to be attained in ten seconds, in a distance of about sixty yards In the Twickenham Teddington route the vehicles are double decked 56-seaters They are fitted with an 80 horse-power 500 volt motor, and the speed control is effected by a pedal which actuates an electric controller Three braking systems are provided, hand, rheostatic, and vacuum, the two latter being operated in succession from one pedal Retardation can be effected at eight feet per second per second for ordinary stops, and at twelve feet per second per second for emergency stops, these rates being uniformly maintained until the vehicle comes to rest Thus in an emergency a bus that is running at thirty miles an hour can be brought to a standstill in about eighty feet

WHEN the last estimate for the Reichskuratorium fur Wirtschaftlichkeit was passed by the Reichstag, a recommendation was put forward that in all investigations on rationalisation carried out at the public expense the human factor should receive special study An official conference to discuss rationalisation and the human factor was held in Berlin on Feb 27 and 28, the conference being opened by the president of the Board of Trade and a representative of the Ministry of Labour The programme was divided

into two sections, the first, on the optimum organisation of labour, being opened by papers on recent discoveries in the field of labour psychology (Dr Lipmann), practical investigations to ascertain the optimum organisation of labour (Dr Ascher), and measures taken by employers to introduce the optimum organisation of labour The discussion was unusually animated, and was guided by the Reichskuratorium by means of statements, opposing statements, and syntheses of the communal and individual points of view The second section was concerned with vocational selection and training The discussion in both sections indicated the divergent views held on rationalisation, and also the ease with which the gap could be bridged by eliminating misunderstandings due to differences of language and definition, and by concentrating on views common to all parties The Reichskuratorium is following up the conference by a closer study of the special fields, and their investigation by the central organ of the German rationalisation movement should ensure that they are studied less from the personal than from an unbiased scientific point of view

IN his address on "Industrial Administration" before the Association of Technical Institutions, Mr A S Comyns Carr referred to the scant attention which industrial administration had received from the majority of those engaged in industry, in spite of its necessity in every industrial enterprise This want the Institute of Industrial Administration is endeavouring to supply Regarding industrial administration as the co ordination and control of all the activities of an industrial enterprise, from the purchase of the raw material to delivery of the finished product, the Institute seeks to provide the industrial administrator or general manager with sound information on the principles which his experts should follow The effort to establish industrial administration among the recognised professions is already leading to the recognition that management occupies a unique position in industry That position involves responsibility not merely to the proprietors of the business but to those employed by it, and also towards the public

THE Institute of Industrial Administration sets as its first aim the establishment of industrial management as a responsible profession The promotion of research into the principles of management is a further main line of advance, particularly in Great Britain, where the spirit of secrecy has greatly hindered the interchange of information on management methods and principles, which is a first step towards raising the general standard of administration Referring to the educational work of the Institute, Mr Comyns Carr asserted the importance of teaching the principles of administration Once these are understood, the appropriate system for meeting with a given set of conditions will easily be developed In discussions on the need of first class administrators for industry loose references to the importance of personality tend to obscure the need for training Personality is not a substitute for training, and the Institute of Industrial Administration insists that management requires real qualifications and not the accidents of financial interests or family relationships

IN view of the great development of the work of the Long Ashton Research Station of the University of Bristol, the governing body of the Station has recently formulated a new scheme of membership of the Station This scheme provides for three classes of members, on a basis of varying rates of annual subscription to the Station, the privileges of the members in the three classes being graded according to these rates Class A, on a subscription of £1 1*s*, allows the member to consult the staff without fee, to purchase at preferential rates any material of the nature of buds, grafts, cuttings, or plants of any varieties of fruit, to submit, without charge for examination, not more than six samples of cider and perry annually, and to have priority over non subscribers in respect of any advisory services Class B, entailing a subscription of £2 2*s*, includes all the privileges of Class A, also to receive one copy of reprints of papers published by the staff, and to participate in the seedling distribution scheme, which has been adopted after consultation with the Ministry of Agriculture and Fisheries and the Horticultural Trades Association Class C for which the subscription is £5 5*s*, differs from Class B only in the seedling distribution scheme

THE original air maps of the United States, which were first published a few years ago, were known as strip maps, because, individually or in series they covered strips of territory 80 miles wide between one airport and another Of the 42 sheets planned, 22 are now completed and 7 are in hand The Annual Report of the United States Coast and Geodetic Survey for the year ending June 30 1930, announces a new project in air maps Since 80 per cent of flying is now over routes which do not follow the airways provided with strip maps, it has become necessary to have a map covering the whole country This will be provided in 92 sheets excluding Alaska It will be based on the United States topographic map, which, however, is available for only about 40 per cent of the country The Report announces also that financial resources have now been provided for the completion of the topographic map in some twelve years time This will allow the air map to follow rapidly

AT a meeting of the Royal Society of Arts on May 6, the Earl of Crawford and Balcarres made a strong plea for the retention of the natural and artificial beauties of England, in an address upon 'The Preservation of the Country side The appositeness of the speaker's remarks and the need for his criticism of many tendencies of present day development were emphasised by a series of lantern pictures of England spoilt and unspoilt The text of the address was "orderliness, tidiness, and discipline", and the illustrations showed how much could be accomplished by the application of these qualities, none of which was incompatible with the picturesque and the inspiring Amongst the special points dealt with were the litter nuisance, the choice of building materials, ribbon

development of building (a serious and very important issue), and the value of trees. The address and the comments made upon it by various speakers, including Mr. Cass Gilbert, the architect of the Woolworth Building in New York, appear in the *Journal* of the Society for June 5.

As announced in NATURE for March 7, the 'Dechema' (Deutsche Gesellschaft fur chemisches Apparatewesen) held its general meeting in Vienna on May 28 and 29 at the same time as did the Verein deutscher Chemiker. The scientific proceedings were well attended, and the papers which were communicated on 'The Separation of Liquids and Solids" aroused wide interest. In all, twelve papers were communicated dealing with filtration in the laboratory and on the technical scale, the latter being naturally in the majority. We are informed that this interesting series of lectures will shortly be published in volume form of the 'Dechema' Monographs. On May 30 those taking part in the general meeting were able to visit the almost completed new Institute of Chemical Technology of Inorganic Compounds, a part of the Vienna Technical High School. This Institute provides an almost ideal solution of the problem of enabling the students to work with apparatus which corresponds to factory scale conditions.

IN connexion with the International Illumination Congress which is being held in Great Britain next September, the General Council of the Congress has issued a booklet on the origin, organisation, and work of the International Commission on Illumination, under the auspices of which the Congress is being held (International Illumination Congress, 1931, 32 Victoria Street, London, S.W.1). Its object is the provision of an international forum for all matters relating to the science and art of illumination, and the International Commission at the present time has national committees in Austria, Belgium, Czechoslovakia, France, Germany, Great Britain, Holland, Hungary, Italy, Japan, Sweden, Switzerland, and the United States. Meetings of the Commission are held every three years, the last being held in the United States in 1928. This meeting was attended by 71 delegates from nine countries, while the Congress held just previously was attended by 514 delegates. Among the more important work of the future is that of securing international agreement on the fundamental bases of illumination, the standardisation of illumination materials, and international agreement on illumination legislation. Added to this, is the necessity for research and the education of public opinion to the value of good lighting. The booklet includes an article on "The International Commission on Photometry", the names of the officers of the Commission, and lists of the papers read in 1921, 1924, 1927, and 1928.

THE Report on the work of the Department of Petroleum Technology of the Sir John Cass Technical Institute for the session 1930–1931 is to hand, and, as in the past, shows a creditable record of progress. This constitutes the tenth session during which provision has been made for instruction in petroleum technology, and it is significant of the farsightedness of the sponsors of the courses involved that little material departure from original schedule has been found necessary during that time. Students are drawn principally from the clerical, distributive, and technical branches of the industry, and the average number per session, taken over the whole decade, who have profited by the teaching at the Institute, is one hundred. During last session, courses were provided on general technology of petroleum, on internal combustion engines and lubrication, on chemical and physical properties of petroleum and its examination, on the applications of engineering to industry, and on construction of works. The past session was also marked by a striking increase of the number of student hours, from 2876 previously to 4144, a testimony to the keenness of the members of these classes and a source of gratification to the teaching staff.

AN important congress of naval architects will be held in Paris on June 29–July 4 at which papers will be read dealing with shipbuilding, marine engineering, and civil aviation. The meeting will be confined to members of the Institution of Naval Architects (London) and members of the Association Technique Maritime et Aeronautique.

THE United States Government sets a good example in the matter of industrial statistics. Much of interest can be culled from even the dry bones of such documents as "The Coke and By Product Tables for 1929", compiled by the U.S. Bureau of Mines, Coal Division (Washington, D.C.). It throws interesting light on the immense American carbonising industry. In 1929, nearly sixty million tons of coke were produced – an increase of 50 per cent on the figures of 1915, but the proportion made in by product ovens had grown in that period from one third to 90 per cent of the total. The coke is mainly used as metallurgical fuel, but an increasing proportion is going into the domestic 'furnace'. The immense quantities of tar cannot be absorbed for manufacturing purposes, and more than one-half is consumed as fuel, mainly in the steel works, the average price being 5 cents a gallon. The surplus gas is used mainly as industrial fuel and commands an average price of 16 cents a thousand cub. ft., but up to 29 cents for use as town's gas. These figures are instructive in indicating the limits set by economic circumstances to the extension of coal carbonisation.

THE observatory of De Bilt lies about 40 miles east of the Hague. The seismological section, founded in 1904, possesses a pair of Galitzin's horizontal seismographs and his vertical seismograph with the usual magnetic damping and galvanometric registration, one of Wiechert's astatic horizontal pendulums, and a pair of Bosch horizontal pendulums. The first number of the *Seismische Registrierungen* contains the records for part of 1904 and for the interval April 1908–1913. Since then, the numbers have been published annually. We have recently received the sixteenth number, that for the year 1928, compiled by Dr. G. van Dijk, the director of the seismological section. It contains the records of

433 earthquakes, giving, as usual, the epoch, period, and amplitude of the various phases, and, with very few exceptions, the approximate position of the origin

APPLICATIONS are invited for the following appointments, on or before the dates mentioned —Two chief assistants in the department of psychological medicine of St Thomas's Hospital—The Secretary and Clerk to the Governors, St Thomas's Hospital, S E 1 (June 30) A labour superintendent at the ordnance factories of the Royal Arsenal, Woolwich, with workshop training in an engineering establishment—The Under Secretary of State (C 5), War Office, S W 1 (July 3) A Sir Ernest Cassel reader in commerce at the London School of Economics—The Academic Registrar, University of London, S W 7 (July 6) A lecturer in agriculture under the Hertfordshire County Council—The Clerk of the Hertfordshire County Council, 28 Castle Street, Hertford (July 7) A head of the engineering department, a lecturer in mechanical engineering and drawing and a graduate lecturer in electrical engineering (with physics and mathematics as subsidiary subjects) in the engineering department of the Merchant Venturers' Technical College, Bristol, also a head of the building department, a lecturer in building construction and building subjects, and a graduate lecturer in chemistry and physics (with mathematics as subsidiary subject) in the building department of the Merchant Venturers' Technical College, Bristol—The Superintendent, Merchant Venturers' Technical College, Bristol (July 7) A full time lecturer to take charge of the electrical engineering department of the Chesterfield Technical College—The Principal, Technical College, Chesterfield (July 11) A pathologist at the National Hospital for Diseases of the Heart—The Secretary, National Hospital for Diseases of the Heart, Westmoreland Street, W 1 (July 11) An assistant master, to teach mainly science subjects in the junior technical school and engineering departments of the Bolton Municipal Technical College—The Director of Education, Education Offices, Nelson Square, Bolton (July 11) A lecturer in chemistry at the Technical College, Sunderland—The Chief Education Officer, 15 John Street, Sunderland (July 11) An assistant lecturer in physics in the University College of Wales, Aberystwyth—The Secretary, University College of Wales, Aberystwyth (July 11) A lecturer in philosophy at Jesus College, Oxford—The Principal, Jesus College, Oxford (July 11) A lecturer in physics at the Northampton Polytechnic Institute—The Principal Northampton Polytechnic Institute, St John Street, E C 1 (July 13) An assistant lecturer in physics at University College, London—The Secretary, University College, Gower Street, W C 1 (July 13) An assistant lecturer in chemistry in the University of Sheffield—The Registrar, University, Sheffield (July 13) A demonstrator in civil engineering and surveying at the City and Guilds (Engineering) College—The Secretary to the Delegacy, City and Guilds (Engineering) College, Exhibition Road, S W 7 (July 15) A woman professor of mathematics at the Huguenot University College, Wellington South Africa—The Secretary, Office of the High Commissioner for the Union of South Africa, 73 Strand, W C 2 (July 31) A Savilian professor of astronomy in the University of Oxford—The Registrar, Old Clarendon Buildings, Oxford (Oct 10) A director of research of the British Launderers' Research Association—The Secretary, British Launderers' Research Association, 17 Lancaster Gate, W 2

Our Astronomical Column

Tempel's Comet 1866 I —This is the comet associated with the November meteors, it has a period of about 33 years, but was not recovered at its return in 1899 In the hope of facilitating its recovery at the forthcoming return, the computing section of the British Astronomical Association undertook the computation of the perturbations from 1366 (when a comet, believed to be the same, was observed) to 1866 and onward to 1933, the results are published in the April number of the *Journal* of the Association, and were supplemented by a further statement at the meeting on May 27 The deduced orbit for the next return is found to be nearer the earth's orbit by half a million miles than it was in 1899, which gives hopes of a better display of meteors The most hopeful dates for meteors are 1932 Nov 16 5 and 1933 Dec 16 8, but search should also be made on 1931 Nov 17 3

The first rough date announced for the comet's perihelion passage was 1933 May 4, but revision of the work has made this some three months earlier, or the end of January, in 1866 perihelion was on Jan 11, so if the date is only slightly later than this, there will be good hope of observing the comet There is still uncertainty of a month or more either way in the predicted date, but before the investigation the uncertainty was quite two years, so that it has been notably reduced The recovery of the comet is highly desirable, it would make possible the accurate study of its motion in the past, and would verify, or otherwise, the conjecture of Le Verrier that the comet and meteors owed their introduction into their present orbit to the action of Uranus in A D 126 Some textbooks refer to this conjecture as an established fact, but it is not so, however, the near approach of the comet's orbit to that of Uranus makes it likely that there was a close appulse of the two bodies at some epoch

The Distance of the Galactic Centre —*Astr Jour*, No 957, contains articles by P van de Kamp on the distance of the galactic centre and the thickness of the galactic absorbing layer He notes that the existence of this layer, first announced by Trumpler, has been further confirmed by Schalen, Ohman, Miss Slocum, and himself Hubble's work on the spiral nebulæ gives further support, as he finds an irregular zone of avoidance of such nebulæ along the Milky Way, while their distribution elsewhere is fairly uniform The thickness of the layer is given as 210 parsecs, with a probable error of 40

The distance of the centre of the galaxy is found from (1) the centre of the system of globular clusters, (2) from a study of cluster type variables in a Milky Way field, (3) from the constants of galactic rotation The extreme values of the distance of the centre in parsecs are 16,700 and 7000 He suggests 12,000 as a mean (say 40,000 light years) This implies an absorption intermediate between Trumpler's value and that of Bottlinger and Schneller, it would be somewhat over a magnitude at 1000 parsecs

Research Items.

An Aboriginal Tasmanian Skeleton.—In *Man* for June, Mr. Gilbert Rigg describes human bones forming part of a skeleton, which was found in a shelter at the head of the Mersey river. The skull lacks the lower jaw and the incisors and canines of the upper. The bones show considerable weathering and are stained a light to dark brown. The specimen is a male, judging from the pelvis; and the teeth are greatly worn on the crowns, so that it would appear that he was not a young man. The sutures of the skull are unclosed. He was, therefore, probably under middle age. The teeth show no sign of caries, but an abscess has corroded the roots of the first and second molars on the right and has eaten well into the jaw. The wear of the teeth is partly due to the nature of the food, which included a large proportion of shell fish. Sand doubtless found its way into the food. The principal measurements of the skull are: *Max. length*, glabella to occiput, 185.5 mm.; *Width*, across parietal bones, 135 mm.; across temporal lines, 97.5 mm.; *Max. zygomatic width*, 134 mm.; *Height*, above earholes, 116 mm.; *Cephalic Index* 72.8; *Cranial capacity* (Pearson and Lee's formula), 1368 c.c.; (shot) 1340 c.c.; *Palatal width*, across the outer borders of the second molars, 69.8 mm.; length (by estimate) 63.3 mm. The measurements bring out the great size of the teeth, a characteristic of Tasmanian aboriginals. Among the other bones the atlas is present and six dorsal and lumbar vertebræ. One scapula only is present, the left, and only the right humerus. The left half of the pelvis is missing. Both femora are present, but only one tibia.

The Hares of Japan.—Yoshio Abe has followed up his researches upon the seasonal changes of colour in the variable hare of Japan by making a systematic study of the species. He regards it as differing from any of the northern varying hares and designates it a new variety, *Lepus brachyurus etigo* (*Jour. Sci. Hiroshima University*, Ser. B, Zoology, March 1931). The mixture of elements which make up the present fauna of Japan, derived partly from Saghalien in the north and partly from Japanese-Corean forms and more southern forms, travellers across former land bridges, makes the resolution of the hare species no easy matter, and Abe is inclined to differ on several points from previous workers. He recognises nine Japanese species and races, and in addition to the Etigo hare mentioned above, describes as a new race of the variable hare, the Saghalien hare *Lepus timidus saghaliensis*.

Ancestral Peculiarities in Lower Jaw of Elephant.—In the course of a detailed examination of the anatomy of three fœtal elephants, Dr. Nellie B. Eales has found, in the form and set of the mandible, traces of an ancestral character (*Proc. Zoo. Soc. Lond.*, April 1931). In an adult elephant, the mandible is deflected and the pre-alveolar border is useless, a unique condition. In the fœtal specimen examined, however, the deflection was greater than in adults, and the mandibles were of longirostrine type, in this respect suggesting some of the extinct forms of proboscidians. During early post-natal development, the jaws shorten, and gradually become like those of their parents. Dr. Eales looks upon the modification as an embryonic repetition of the phylogeny of the race.

Birds of Hispaniola.—In an account of the "Birds of Haiti and the Dominican Republic", Alexander Wetmore and Bradshaw H. Swales discuss the most interesting avifauna in the West Indies; for the island of Hispaniola, so named by Columbus on its discovery, has preserved in its high mountainous tracks remnants of an ancient fauna which has elsewhere disappeared in the archipelago (*U.S. Nat. Museum Bull.* 155, 1931). Though the island has from time to time yielded many peculiar forms, it is only within recent years that the significance of the fauna as a key to the problems of distribution in the Antilles has been understood. The resident forms fall into two principal groups, one of species found on the coastal plain or foot hills of the interior, and the other a much smaller body confined to the high mountains of the interior. The former series contains members which range at large over the entire main island and may extend even through the adjacent Greater Antillean islands. It has a few peculiar species, elsewhere unknown, like the flat-billed vireo (*Lawrencia nana*) and the palm chat (*Dulus dominicus*). The high mountain series, including such as the cross-bill (*Loxia megaplaga*), several thrushes, a warbler, and others, are highly peculiar in occurrence and seem to represent remnants of an ancient fauna of general distribution, which has since disappeared except on the mountain ranges of the island, the most extensive area of elevated land in the West Indies.

Kidney Worm of Pigs.—I. Clunies Ross (*Jour. Council Sci. Ind. Res. Commonwealth Australia*, vol. 4, No. 1) records observations on *Stephanurus dentatus*, the kidney worm of pigs, which is found when mature in small fibrous capsules opening into the pelvis of the kidney, while larval stages and immature adults are found also in the liver, lungs, thoracic cavity and sub-lumbar muscles. This parasite is firmly established in the north-east coastal region of Australia but is scarce south of Sydney. The eggs of the worm pass out with the urine and hatch in a minimum period of 16 to 24 hours. The microscopic larvæ develop in mud, and in about five days, having undergone two ecdyses, are able to infest pigs. They may survive for five months under suitable conditions of heat and moisture. The larvæ may be swallowed by the pig or may enter through its skin (this is confirmed by Dr. Kauzal), and in either case reach the liver, where they grow rapidly while wandering in the liver tissue and causing great destruction thereof. Only after five or six months' development do the worms, now adult but immature, take up their final position in the vicinity of the kidney or ureter, where their presence gives rise to the formation of the fibrous sacs in which the male and female worms are found. The author points out that in well-drained and clean sites or in sanitary yards it is possible to decrease the danger of infestation and even to effect complete eradication of the worm.

Notes on Ostracods.—Mr. A. G. Lowndes, in his paper "Some Rare and Little Known British Freshwater Ostracods", published in the last Report of the Marlborough College Natural History Society (No. 79), records a number of species of ostracods, mostly from the Marlborough district, two of which are new to the British Isles. Detailed descriptions are given, and the paper is illustrated by microphotographs and by line drawings. In a second paper by the same author, "On Entomostraca from the New Hebrides collected by Dr. J. R. Baker", (*Proceedings* of the Zoological Society of London, 1930, published January 1931), some interesting observations are made, especially on the ostracod *Stenocypris malcomsoni* Brady, well known from tropical countries. The material is from a large lake on the island of

Gaua, two samples of dried mud also being collected, from one of which, taken in shallow water, a good culture of *Stenocypris* was obtained. The male is unknown and all the culture specimens obtained were from parthenogenetic females. A good deal of variation is found among the individuals in a culture, especially in the armature of the caudal furca, and good figures are given showing the differences.

Eradication of Prickly Pear in South Africa.—Although not yet such serious pests as they have proved in Australia, various species of *Opuntia*, indigenous to America and possibly introduced in the first place in cultivation, are now spreading in South Africa. C. R. van der Merwe, in *Science Bulletin* No. 93, issued by the Department of South Africa, gives some account of the spread of these species in the Cape Province particularly, and discusses possible methods of eradication, in the light of the extensive Australian experiments in this direction at the Dulacca Prickly Pear Experiment Station and of recent South African experiments at Uitenhage, which have been designed to test Australian methods under South African conditions and against the species particularly rampant in South Africa. These, which are described, are given as *O. monacantha*, *O. maxima*, *O. megacantha*, and *O. aurantiaca*. Where dense stands of prickly pear are encountered, it is concluded that the methods of eradication which seem most effective require a combination of spraying and injection with soluble arsenical compounds.

Electricity in Horticulture.—Electricity is at present little used in horticulture, but since market gardening is usually carried out on intensive lines and in concentrated areas, there seem better prospects of its proving an asset in this industry than in farming. In a recent article (*Jour. Min. Agric.*, 38, p. 132), C. A. Cameron Brown shows that a considerable amount of experimental work on this question is being undertaken, some of which seems suitable for development on a large scale. Electricity as a source of bottom heat appears to be particularly promising. Electric hot beds are already employed successfully on the Continent, and it is not improbable that an extension of this system would lead eventually to some replacement of the usual manure hot bed with its obvious disadvantages. The investigations regarding the use of power for cultivation, and electric light for increasing plant growth are less far advanced. Various cultivation implements have been designed, notably in France, but their cost of production is at present too high to merit their use on a commercial scale. Extension of the length of day by artificial lighting has been definitely shown to improve the growth of plants, but more experiments are required before it is certain that such treatment can be considered an economic proposition.

New Zealand Glaciation.—A report on evidences of past glaciation in New Zealand and Australia by Dr. P. Marshall is given in the *Report* of the twentieth meeting of the Australian and New Zealand Association for the Advancement of Science (Brisbane, 1931). The work was the result of a research committee appointed at the previous meeting. There is held to be no evidence of Silurian or of any other glaciation previous to the considerable extension of the present glaciers in late Pleistocene to recent times. Even that extension would appear to be of much smaller extent than was previously supposed. Large accumulations of gravels in several areas in Central Otago are now ascribed to fluviatile origin previous to the development of glaciation. In the North Island there seems to have been no glacial development on the high volcanoes or on the central mountains from Cape Runaway to Cook Strait. The report also summarises the evidence for glaciation in Cretaceous times in New South Wales and in Permo-Carboniferous times in Western Australia and Victoria.

The Structure of Incandescent Carbon.—In a recent *Scientific Paper* (No. 299) from the Tokyo Institute of Physical and Chemical Research, M. Hirata has given an account of an X-ray study of carbon. The specimens were mounted as poles of an arc, and the X-ray diffraction patterns produced by them photographed both with no current passing and with the carbons kept incandescent by having the arc burning. The main object was to find if the surface of either pole became liquid at the high temperatures reached (4000° C.), but although part of the pattern due to the position pole could be accounted for in this way, the results were inconclusive. From the change in *spacing of the diffraction rings between room temperature* and incandescence, it has been shown that the expansion of the graphite occurs almost completely in a direction perpendicular to the most closely packed plane, the average value of the expansion coefficient being $4 \cdot 10^{-5}$ per degree, which is much larger than the expansion coefficient at lower temperatures.

The Electrical Failure of Crystals.—It is known that if potential surges of short duration are applied to crystals discharge tracks appear in the solid which are not unlike Lichtenberg figures in form, and follow definite crystal axes. The extension of these observations to the practical case of failure of crystals under prolonged electric stress is described by J. Lasz in the *Zeitschrift für Physik* for May 12. Asymmetrical fields were applied between point and plane electrodes in rock salt, fluorspar, gypsum, and calcspar. When the temperature was not too high the channel formed by the spark followed directions defined by the crystal axes, being usually built up of a number of straight sections, and not following the shortest line from point to plane; when a track forked, each branch made its own channel on similar lines. The effect of the spark appeared to consist in a plastic deformation of its immediate neighbourhood, followed later by local shattering and fusion. At higher temperature the directing effect of the crystal axes disappeared and the spark passed in the region of greatest field strength. It is remarkable that the average field needed for the disruptive discharge is much smaller than has been calculated theoretically by Rogowski.

Rare Earth Metal Amalgams.—Of the sixteen rare earth metals, only six have been obtained in the free state (Y, Ce, La, Nd, Sm, Eu), and only two (Ce, La) in a high state of purity. Audrieth, Jukkola, and Meints, working in collaboration with Prof. Hopkins, of Illinois, describe some interesting experiments in the May number of the *Journal of the American Chemical Society* which show that it is possible to prepare rare earth amalgams electrolytically not only from aqueous but also from absolute alcoholic solutions. The paper deals with the amalgams of lanthanum and neodymium; work on other amalgams, and the separation of the metals from them, is contemplated. The amalgams are extremely reactive and undergo ready decomposition. By heating the neodymium amalgam in vacuo much of the mercury was removed, but some remained even at the temperature at which pyrex glass begins to melt. The product thus obtained was a black powder which readily takes fire in air. By heating this powder in a tungsten boat in a high vacuum furnace the remaining mercury was eliminated, and the neodymium metal could even be volatilised with the deposition of an extremely reactive film of the element.

Canadian Coal

By a Canadian Correspondent *

AMONG the most abundant of Canada's natural resources, coal is near the head of the list A comparatively recent estimate placed the coal reserves of the Dominion at more than 1,234,000,000,000 metric tons, or about 16 per cent of the world's coal reserves

The principal coalfields of Canada are in Nova Scotia, Alberta, and British Columbia, while the chief centres of industry and population are in Ontario and Quebec 2000 miles to the east and 1000 miles to the west The great coalfields of the eastern United States lie only 300 500 miles to the south of the southern boundaries of Ontario and Quebec, and from those fields these two provinces import most of their coal, because it is more economical to do so For the past thirty years Canada has imported from 50 to 60 per cent of its total coal requirements from the United States

Ever since Confederation in 1867, it has been the aim of every government to make it possible for Canadian mines to obtain a larger proportion of the total coal business Until recently, efforts in this direction have been confined to the imposition of protective tariffs, but lately this has been supplemented by more direct forms of assistance, such as by the Dominion Government paying a share of the freight rates on coal from western and eastern mines in Canada to points in Ontario, Quebec, and Manitoba, also by extending some monetary aid under the Domestic Fuel Act of 1927 to by product coking plants

Nine years ago, an organisation known as the Dominion Fuel Board came into being by government regulation It was formed to make a thorough study of the underlying causes of recurring coal shortages and of the methods by which they might be counteracted Since then the Board has been largely instrumental in stimulating the provision of fuels alternative to American coal for Ontario and Quebec, and is chiefly responsible for the greatly increased importations of British anthracite in the last three years

Of the Canadian coal production in 1930, amounting to 14,799,000 tons, less than 750,000 tons was exported, and it does not appear that there is much likelihood of the export market being increased The possibility of extending the home market by supplanting American coal with the Canadian product has been engaging the attention of the Fuel Board To the end of 1930, government assistance in the form of subventions and the operation of the Dominion Fuel Act have resulted in the placing of 900,000 tons of Canadian coal and coke in markets previously held by foreign coal

The character of the mining problems presented in the coalfields of the maritime Provinces indicates that the present production of between six and seven million tons cannot be increased more than perhaps 50 per cent above present figures If this were accomplished, the total production of these fields would still fall short of supplying the present requirements of Canada, east of Ottawa and Kingston, by from one to two million tons per annum

At the present time, maritime coals supply approximately seven million tons out of a total consumption of eleven and a half million tons It is evident, therefore, that eastern Canada must look to other countries for a considerable part of its needs

In the west, the capacity of existing mines is far in excess of present needs Total requirements of the western provinces are about ten and a quarter million tons About half a million tons are imported from the United States, chiefly to Manitoba British Columbia in past times had a good export market to California, but this has diminished greatly. Total exports of Canadian coal from the western fields are now only about 400,000 tons

The lack of coal resources in Ontario and Quebec has been compensated to a large degree by the development of the abundant water powers of these provinces There is now approximately six million horse power developed In terms of coal, this is the equivalent of eighteen million tons, an amount more than the total Canadian coal production

The use of fuel oil is increasing rapidly In 1929 the latest year for which complete figures are as yet available, the total consumption of fuel oil in the Dominion outside the refineries was more than 413,000,000 gallons—an 18 per cent increase over 1928 The consumption of fuel oil in 1930 is expected to show a small increase The coal equivalent of the present consumption is approximately three million tons The competition of fuel oil is being particularly keenly felt in British Columbia coal mines Cheap oils from California and Peru have replaced nearly one million tons of coal in British Columbia The bulk of this oil is used by the railways

In 1930, Canada imported 17,728,991 tons of coal, of which 13,463,601 were bituminous and 4,265,390 anthracite Of the total imports of bituminous coal, 13,217,369 tons were from the United States and 146,232 tons from Great Britain Of the anthracite imported, 2,965,254 tons were from the United States, 996,127 from Great Britain, 292,529 from Russia, and 11,480 from Germany

Last year, Canada consumed 31,870 tons of coal and 3,385,000 tons of coke—a decrease of 3,000,000 tons from the average consumption of the previous two years Central Ontario consumed approximately thirteen million tons, Quebec five millions, Alberta four and a half millions, and Nova Scotia three and three quarter millions

Of the total Canadian coal production last year, the mines in Nova Scotia accounted for 6,247,761 tons, New Brunswick, 208,405, Saskatchewan, 571,632, Alberta, 5,682,487, and British Columbia, 2,089,052, a total of 14,799,337 tons valued at £10,600,000 The coal mining industry in Canada represented at the end of 1929 a capital investment of £28,400,000 There were at that time 29,739 employés in the industry, whose salaries and wages bill totalled for the year £8,475,000, or about £285 per employé

As a step towards the more economical utilisation of domestic fuel supplies, pamphlets have been published dealing with the advantages to be gained through proper insulation of houses and factories, and the maintenance of adequate humidity in them The question of proper humidity in houses subject to a Canadian winter climate is one which closely affects standards of health as well as fuel economy, and investigations on these subjects are being continued

Canadians are fully aware of the advantages to be gained through the development of a national fuel policy, which will assure to them the fullest possible use of their own fuel resources consistent with reasonable economy in the distribution of them Where factors of transportation prohibit the realisation of this aim, effort is concentrated in finding a source of supply within the British Empire That these aims have met with a measure of success is evidenced by the increasing imports from Great Britain

* This article is based upon information derived from various official documents and the records of the Department of Mines, Ottawa

Annual Assembly at Rothamsted Experimental Station.

THE annual assembly of subscribers to the Rothamsted Experimental Station took place on June 18, when demonstrations of the field experiments and of the work going on in the various laboratories were given As the time available for the inspection of the fields was short, only a limited number of the trials were inspected, these included the classical experiments on the Park Grass begun in 1856, and the one on the famous Broadbalk wheat field started in 1843 The first was designed to show the effect of different fertiliser treatments on the yield and character of the herbage, and to-day it forms a very striking illustration of the way in which the farmer can affect the nature of his pasture by varying the plant nutrients supplied The second experiment was originally intended to show the effect of nitrogen, potash, and phosphorus on the growth of the wheat plant, the action of these three substances is now well known, but the experiment is still yielding valuable information for example, a few years ago a study of the yields from the various plots, with the weather records, enabled the statistical department of the station to deduce valuable correlations between rainfall at different seasons of the year and the yield More recently, by studying the average yield of the plots, the physics department has been led to the study of certain soil characteristics

The average yield of the plot receiving a full annual dressing of artificial manure has been very close to that of the plot receiving farmyard manure, but the economic value of the two crops has not been equal, since the dunged plot has yielded relatively more in unfavourable seasons, when prices were higher It is a matter of great importance to discover why the yields on the dunged plot have been less at the mercy of the vagaries of our climate The increased microbiological activity induced by the addition of organic matter is undoubtedly the primary reason, and it influences the yield partly by the production of soluble chemical nutrients and partly through the formation of humus, which gives a more open structure to the soil and, incidentally, gives it the black colour characteristic of a 'rich' soil The problem of ascertaining just how the presence of humic matter affects yields is bound up with the wider question of how the nature of the soil and the cultivation treatment it receives influences the growth of the crop and its response to manuring Work, therefore, on the stability of soil crumbs formed in the field under different systems of cultivation, and by sheep treading, is being followed up in the laboratory, where an attempt is being made to discover the nature of the forces which bind soil particles together The prosecution of this inquiry has involved excursions into pure science, particularly colloid physics and physical chemistry

These problems are part of the general one of land utilisation In many soil surveys only qualitative tests have been applied, owing to the large amount of time and money needed in using the existing laboratory methods Several new ways of determining the physical properties of a soil have been worked out at Rothamsted These are quantitative and, at the same time, very rapid In their development the needs of those responsible for irrigation projects in salty areas have been particularly kept in view

In addition, however, to the old classical experiments, more modern ones, designed to meet the needs of modern agricultural conditions, have been devised As an example, the six course rotation in Long Hoos field and the forage crop in Little Hoos may be cited

The main object of the six-course rotation is to obtain data by means of which the influence of climatic conditions in different seasons on the response of crop yield to artificial fertilisers may be studied The rotation is barley, clover, hay, wheat, potatoes, a forage mixture (rye, beans, and vetches) and sugar beet, and each crop is grown every year Sulphate of ammonia, superphosphate, and muriate of potash are used, and there is a range of five intensities of manuring for each fertiliser

The nature of the problems to be investigated in these experiments necessitates continuance over a long period of years, but the immediate results will be of interest A feature of the experiment is that the number of years required for a cycle of crops differs from the number required for a cycle of manurial treatments, so that the defect from which older rotation experiments suffered, that the same crop constantly recurred with the same manurial treatment on the same plot throughout the period of experiment, is avoided It is thus possible to eliminate the effects of permanent differences in fertility between the plots

The large experiment of 144 plots, arranged as a Latin square, in Little Hoos field is designed to investigate the effect of different fertilisers on the yield and chemical composition of forage crops consisting of mixtures of cereals and legumes The manuring of such crops presents difficulties which are not encountered when a single crop is grown, since the ability of one constituent to compete with the others in the mixture may be altered by manuring, and the composition and nutritive value of the produce so changed The main problem is to discover by what system of treatment with artificial fertilisers the yield of protein per acre may be increased Four different mixtures are used, consisting of winter oats, vetches, beans, wheat, vetches, beans, winter oats, peas, beans, and wheat, peas, beans The twelve fertiliser treatments include sulphate of ammonia, nitrate of soda, potassium chloride, and superphosphate, separately and in combination

Chemical investigations are being carried out on these crops, which should yield interesting information In 1930 ammonium sulphate increased the amount of cereal straw and depressed that of leguminous plants in mixed forage crops to such an extent that the large increase in total yield was not accompanied by any increase in the yield of protein per acre Calcium cyanamide generally gives similar results to ammonium sulphate, but under less favourable soil conditions it interferes with the normal nitrification process

In the afternoon the laboratories were inspected In the bacteriology department, the investigations made on the nitrogen fixing bacteria forming nodules on lucerne were explained In the past this work has led to a large increase in the area of ground on which lucerne can be grown, and special attention is being paid to the reaction of the organism to the host plant This is usually one of mutual benefit, the plant supplying the bacteria with carbohydrates, and receiving in return a supply of nitrogen compounds If the supply of carbohydrates to the nodule is checked, as by growing the plant in the dark, the bacteria become actively parasitic and destroy the cells of the host

The entry of the bacteria into the root is in some way assisted by root secretions of the host plant, although the manner in which these act is still uncertain

In the chemistry department, the barley crop is studied in great detail, because its value varies more strikingly than that of any other farm crop with the

conditions of growth The amounts of the principal nitrogenous constituents are closely related to the nitrogen contents for a given variety of barley, irrespective of the soil, season, and manuring Further, many of the properties recognised as important in brewing may be deduced from simple analyses on the original barley, and it should therefore soon become possible to place the valuation of barleys on a more rigid and objective basis In the course of the work, a successful laboratory technique for small-scale brewings has been developed

Interesting exhibits were shown by the department of mycology, illustrating racial differentiation and behaviour in fungal species, 'immune' potato varieties infected with wart disease, and the relation of fungal and host nutrition to potato diseases There were also demonstrations of the structure and life history of *Bacterium malvaccarum* and cotton plants growing in chambers under controlled environmental conditions In the Empire Marketing Board virus glass houses, plants were exhibited showing different types of virus diseases, and the physiological, cytological, and entomological aspects of virus research were shown

In the entomology department, the exhibits illustrated the means of control of Cecidomyidæ (gall midges) affecting osier willows, clover, wheat, and other plants, and experiments dealing with the chemotrophic responses of these insects and the extent to which they govern the selection of the host plants The field trials and laboratory observations designed to determine the amount of natural destruction exercised by parasites upon the frit fly and other agricultural pests were also demonstrated

The demonstrations gave the visitors some idea of the scope of the work carried on at Rothamsted, although the time at their disposal precluded an exhaustive tour of the fields and the laboratories

University and Educational Intelligence

BELFAST - The Senate has appointed Dr T Thomson Flynn to the chair of zoology from Oct 1, 1931 Dr Flynn is at present Ralston professor of biology in the University of Tasmania

CAMBRIDGE - The Vice Chancellor gives notice that the Quick professorship of biology will become vacant on Nov 1 by the retirement of Dr Nuttall A meeting of the electors will be held on July 17 The regulations provide *inter alia* that it shall be the duty of the Professor to devote himself to the study of the biology of the cell and generally to promote that branch of science by research and by the superintendence of a laboratory and otherwise Candidates are requested to send in their applications to the Vice Chancellor on or before July 10

The Council of the Senate has put forward recommendations for the three John Humphrey Plummer professorships The chairs are those of mathematical physics, inorganic chemistry, and colloid science

In the case of the chair of mathematical physics, it is recommended that it shall be the duty of the professor to promote the study of theoretical physics in connexion with the Department of Physics and the Faculty of Mathematics, with special responsibilities towards research students in the Department of Physics At the first election, preference shall be given to candidates whose work is connected with atomic physics Before each election to the professorship after the first, the General Board shall consult the Council of the School of the Physical Sciences as to the needs of teaching and research in theoretical physics, particularly in connexion with the Department of Physics, and, if the Board think fit, it shall be specified in the notice to candidates that preference will be given to those whose work is connected with some particular branch or branches of theoretical physics

Mr W H Mills, Jesus College, has been elected reader in stereo chemistry

GLASGOW —The honorary degree of LL D. was conferred on Sir F G Hopkins, president of the Royal Society, and on Prof. C U Ariëns Kappers, professor at the Central Institute for Brain Research, Amsterdam, at the graduation ceremony held on June 17 At the same graduation, the degree of D Sc was conferred on Dr G W Tyrrell for a thesis entitled "The Geology of Arran"

LONDON —Prof W W Jameson, professor of public health in the London School of Hygiene and Tropical Medicine, has been appointed dean of the School, in succession to the late director, Sir Andrew Balfour

The following appointments to University Chairs have been made by the Senate Philosophy (King's College), Dr H F Hallett, since 1919 lecturer in philosophy in the University of Leeds, Medical Industrial Psychology (London School of Hygiene and Tropical Medicine), Dr Millais Culpin

The title of Reader has been conferred upon Mr Sydney Barratt, physical chemistry, University College, Dr L F Bates, physics, University College, and Dr E A Spaul, zoology, Birkbeck College

University postgraduate travelling studentships of the value of £275 for one year have been awarded to John Stuart Anderson and Eric Gwynne Jones Mr Anderson proposes to continue research in the chemistry of the metal carbonyl compounds and related substances at Heidelberg Mr Jones proposes to carry on spectroscopic research at the astrophysical observatory at Potsdam

OXFORD —Applications are invited from members of Magdalen College for the Edward Chapman research prize value £20, for a published piece of original research in physics or chemistry, including the sciences of astronomy, meteorology, mineralogy and geology, zoology and botany, treated from the morphological, palæontological, physiological, or pathological point of view Further particulars are obtainable from Prof H L Bowman, Magdalen College Competing essays must be received by, at latest, Oct 10

THE Foreign Work Committee of Leplay House announces that during the coming August vacation there will be a visit to Poland, including a fortnight in the Carpathians and a few days in Poznan, Cracow, and Warsaw, for historical, geographical, and sociological studies The studies will be under the direction of Mr R E Dickenson A meeting will also be held in the Cantal, with Rocamadour and Le Lioran as the centres, under the direction of Mr D L Linton A students' camp will be held in Yugoslavia Full particulars may be obtained from Miss Margaret Tatton, Leplay House, 65 Belgrave Road, Westminster, S W 1

THE tenth Unity History School will be held this year in Stockholm, under the direction of Mr F S Marvin The general subject will be "The World at Peace A Survey of Post-War Developments" Both English and Swedish lecturers will be taking part, among them being Prof Herbert Dingle, of the Imperial College of Science, who will trace recent progress in the physical sciences; Mr. Hartley Withers, who will deal with financial and economic problems, Mr Unden, rector of Uppsala and ex-Minister of Foreign Affairs, on international law, and Archbishop Söderblom, to whom the Nobel

Peace Prize was recently awarded The date of departure from London is Aug 5 Full particulars can be obtained from the Hon Secretary, Mrs Innes, 29 High Oaks Road, Welwyn Garden City

Birthdays and Research Centres

June 29, 1868 —Dr G E HALE, For Mem R S, honorary director of the Mount Wilson Observatory, Pasadena, California

The spectrohelioscope, spectroheliograph, and spectrograph of my solar laboratory are being used in several combinations for visual and photographic observations of the atmosphere and magnetic fields of the sun A standard form of spectrohelioscope will soon be in operation at twenty five or more observatories distributed around the earth A plan of co-operative research will deal primarily with the question whether auroræ, magnetic storms, and other geophysical phenomena are caused by solar eruptions, as certain observations and theories suggest

The Astrophysical Observatory and Laboratory of the California Institute, conducted in close co operation with the Mount Wilson Observatory, are in process of development Experiments in manufacturing large mirror discs for the 200 inch telescope are under way, with good prospects of ultimate success New auxiliary instruments, including correcting lenses, spectrograph objectives, and radiometers, when tested with the 60 inch and 100-inch reflectors on Mount Wilson, have greatly increased the efficiency and range of these telescopes

June 29, 1885 —Prof W C MCCULLAGH LEWIS, F R S, professor of physical chemistry in the University of Liverpool

The work which has been carried out for some years now in this laboratory belongs, in the main, to the field of bio colloid chemistry, a branch of chemistry which is receiving considerable attention in various research centres So far as our own programme is concerned, it may be said to include four lines of investigation (1) The kinetics and energetics of coagulation or aggregation of typical colloid and other finely dispersed systems, (2) the physico-chemical aspects of denaturation of proteins, (3) the capillary behaviour of finely dispersed systems of biochemical importance, for example, the lipoids and proteins, (4) the kinetics and energetics of enzyme processes In addition to the bio-colloid work, research in photo chemistry and electro chemistry is likewise being carried out by members of the staff

July 2, 1862 —SIR WILLIAM BRAGG, O M, K B E, F.R S, director of the Royal Institution of Great Britain

The determination of the crystal structure of organic substances is the chief object of research of my colleagues and myself in the Davy Faraday Laboratory Our particular object for the moment is the improvement of the apparatus and of the interpretation of the results It seems that advance in the future will depend on observations of the relative intensities of the pencils of X rays diffracted by a crystal. The crystals to be examined are generally very small, weighing only a fraction of a milligram We have therefore been constructing powerful X-ray tubes which should give results plainly, accurately, and quickly

At the same time various interesting crystals are under examination, and, in particular, the long chain compounds. The new X-ray tubes make it easy to observe certain remarkable effects as the substances are heated until they melt

Societies and Academies.

LONDON

Royal Meteorological Society, June 17 —**S Chapman** A theory of upper atmospheric ozone The paper consists of a discussion of the daily and annual variations of the ozone content of the atmosphere in any latitude up to about 50° The ozone is treated as if it were uniformly spread through a layer of air 10 km thick, having the same density as the air at the level of maximum ozone density Convection and diffusion of ozone are neglected The thermal decomposition of ozone ($2O_3 = 3O_2$) is discussed, and estimated to be negligible, except possibly in connexion with an eleven year (sunspot) variation of ozone —**C K M Douglas** On the relation between temperature and pressure in the troposphere It is shown that the high correlation coefficients between pressure and temperature high up in the troposphere are closely related to the constancy of the lapse rate of temperature The correlations between the mean temperature of the column up to 9 km and the temperatures at 3 and 6 km are very high Some factors tending to produce a constant lapse rate are discussed Groups of extreme cases show that when the barometer at sea level is very low or very high the troposphere contributes about half the deviation from the mean Both cyclones and anticyclones can be grouped into systems largely confined to the troposphere, and systems extending to the stratosphere The argument in favour of an advectional theory is developed

PARIS

Academy of Sciences, May 4 — **A Cotton** The optical properties of a liquid placed in a magnetic field and traversed by a beam polarised in any direction Remarks concerning the work of G Dupouy and M Schérer, with special reference to the installation —**Charles Nicolle** Distemper in dogs can be experimentally transmitted to man without apparent symptoms Although man can act as a carrier of the distemper virus, no reaction of temperature or otherwise could be detected —**A Fraenkel** An essential alternation of the axiom of choice —**W Tartakowsky** The totality of numbers representable by a general quadratic or cubic indefinite form —**Mandelbrojt** Functions, holomorph and limited in a semi plane —**Henri Cartan** A remarkable class of domains —**M Pichot** and **P Dupin** The distribution of the velocities of colloidal solutions presenting anomalies of viscosity The flow of water and of a 0 7 per cent gelatine solution between parallel planes has been studied by the Camichel chronophotographic method, and curves are given showing the velocity as a function of the distance from the walls for each of these liquids These curves prove the existence of a central portion flowing *en bloc* in the case of the gelatine solution —**Henri Mineur** Remarks on the mechanics of variable masses —**E Huguenard** A method of mechanical inscription applicable to the recording and reproduction of sounds —**M Pauthenier** and **Mme M Moreau Hanot**: The cylindrical ionised field and the duration of the path of the ions —**V Dolejšek** The ultra-soft X-rays A modification of Osgood's method was used The most intense line obtained was a doublet with an approximate wavelength of 480° A —**G Dupouy** and **M Schérer** The combination of the simultaneous optical effects of magnetic rotary polarisation and magnetic double refraction in a liquid —**Jean Becquerel** and **Louis Matout** The combined effects of the internal electric field of a uniaxial crystal and of a magnetic field normal to the optic axis Variations of the

components of the absorption bands of the ordinary spectrum according to the relative orientations of the incident vibration, of the binary axes, and of the magnetic field Circular polarisation and magneto electric rotary power —**R Gibrat** The optics of uniaxial heterogeneous structures —**Guichard, Clausmann, Billon, and Lanthony** New data relating to the independence of the hardness and hydrogen content of electrolytic metals Reply to criticisms by L Guillet and J Cournot Fresh experimental evidence is given in support of the authors' views —**Augustin Boutaric and Maurice Doladilhe** The adsorption of colouring matters by the granules of a hydrosol —**Georges Fournier and Marcel Guillot** The absorption of the β rays by matter —**Mme Irène Curie** The complexity of the a radiation of radioactinium —**F Joliot** The phenomenon of recoil and the conservation of the quantity of motion The author has repeated Akiyama's experiment and has obtained similar phenomena, but considers unnecessary the hypothesis of an emission of a γ radiation of very great energy – **L Bert and R Annequin** The action of phosphorus pentachloride upon ω chlorallyl benzene derivatives The action of phosphorus pentachloride upon compounds of the type R C_6H_4 CH_2 CH CHCl furnishes a good method for obtaining C_6H_5 CH_2 CHCl $CHCl_2$ and its homologues —**Sébastien Tabetay** On ω ω' dichloroparaxylene, *p* diethylolbenzene, and *p* divinylbenzene —**Mlle M Montagne** The action of organomagnesium compounds on N diethylacetamide —**C Gaudefroy** The orientation of crystals, and of quartz in particular, with the aid of corrosion figures —**F Holweck and P Lejay** Improvements in a transportable instrument for the rapid measurement of gravity The portable type of instrument described and illustrated is an improved form of one described in an earlier communication After being carried 2000 kilometres in a motor car, without special precautions, its accuracy was unaffected —**Ladislas Gorczynski** Some measurements of the diffused solar radiation obtained with solarimeters in the Maritime Alps —**Chung-Hwang Chow** The development of the carpophore in *Coprinus tormentosus* —**M Bridel and R Lavieille** The sweet principle of the leaves of Kaá hê é (*Stevia Rebaudiana*) The dry leaves contain 6 per cent of the glucoside, stevioside This is very sweet, about 300 times as sweet as cane sugar It is not hydrolysed by emulsin, rhamnodiastase, yeast or by powdered *Aspergillus niger*, but 5 per cent sulphuric acid acting for three hours at 100° C gives a glucose and a substance, steviol —**F Fouraire** A new myxosporidium of the genus *Chloromyxum* observed in the carp —**P Lépine** The separation of the antagonistic sexual hormones in extracts of the anterior lobe of the hypophysis —**A. Leulier and B Drevon** The action of the blood serum on morphine chlorhydrate in the presence of hydrogen peroxide Oxydimorphine has been proved to be formed under these conditions – **Ch Dhéré and M Fontaine** The fluorescence spectra of the phycochromoproteids studied in solution and in a living alga —**J Magrou, Mme M Magrou, and E Roubaud** The stimulating action at a distance exercised by certain bacterial suspensions, through quartz, on the eclosion of the mosquito of yellow fever —**J Parrod** The formation of a-arabinotetroxybutyl 4-imidazol at a low temperature, starting with glucose and with levulose in a solution of ammoniacal cupric hydroxide —**Armand Dehorne** New observations on the generalised plasmodium and the merozoite cysts of *Sabellaria spinulosa* —**Ugo Lumbroso and Mlle. H. Van Sant** New strains of bacteria isolated from north African cases of trachoma following Noguchi's technique Three strains of bacteria have been isolated, A, B, and C. Of these, type A differ essentially from the *B granulosum* of Noguchi in the appearance of the colonies, their consistence, their golden yellow pigment, and the absence of fermenting power towards certain sugars attacked by *B granulosum* Type B, and especially type C, show still greater differences —**C Levaditi, J Bardet, A Tchakirian, and A Vaisman** *Gallium*, its therapeutic properties in syphilis and the experimental trypanosomiases *Gallium* has a marked preventive and curative action in syphilis and certain trypanosomiases

CAPE TOWN

Royal Society of South Africa, Mar 18 —**R A. Dart and Nino del Grande** The ancient iron smelting cavern at Mumbwa —**R S Adamson** On a new species of *Aristea* —**H Zwarenstein and I Schrire** The effect of castration upon protein metabolism Total castration of male rabbits leads to an increase in weight and to a 25 40 per cent increase in creatinine excretion 3 months after operation Grafting of testes caused a return to normal within a fortnight. The creatinine excretion of a female rabbit showed a 20 per cent decrease 3 months after removal of the ovaries —**M Fortes** Perceptual tests of general intelligence for international use —**Sir Thomas Muir** (*a*) Note on equalities connecting two sums of squares (*b*) Note on a special alternant of three variables —**J F V Phillips** A sketch of the floral regions of Tanganyika Territory

LENINGRAD

Academy of Sciences (*Comptes rendus*, No 18, 1930) — **N Zelinsky and M Rakuzin** A new simplified procedure for the manufacture of sulphuric acid from plaster of Paris Calcium sulphate can be converted, by boiling with ammonium carbonate, into ammonium sulphate and the latter electrolysed to produce sulphuric acid —**A Arkhangelskii and E Salmanson** : A note on the diagenesis of the marine argillaceous deposits The chemical side of the processes connected with the interaction of particles of soil and the sea water is discussed —**L Broude and V Gulevitch** The use of Buchner's press for the studie of animal extractive substances The press can be applied successfully in qualitative studies on extractive substances from muscles, but the amount of the extract is never complete and the method cannot be recommended for quantitative studies —**V Nikolaev and S Kosmann** On the boracic acid of the Tchokrak salt lake Analyses of the lake water —**N Achyeser** . (1) On certain polynoms of minimum deviation. (2) On the extremal proprieties of certain fractional functions

SYDNEY

Linnean Society of New South Wales, Mar 25 —**Germaine A Joplin** Petrology of the Hartley District. (1) The plutonic and associated rocks The plutonic rocks at Hartley occur as a portion of a large bathylith, and in two stocks, each of which is about one mile in diameter Hypabyssal rocks occur in the form of dykes and apophyses associated with the bathylith A number of different types, ranging from ultra-acid to ultra-basic, have been described, and mineralogical and chemical evidence points to consanguinity among them The complex forms a typical calcic, or sub-alkaline suite, and is comparable to one of similar age at Moruya It is probable th[illegible] the various types have been developed as a result fractional crystallisation in an intercrustal reserv[illegible] followed by separate injections of the fractio[illegible] differentiation *in situ* The plutonic rocks [illegible] trusive into Upper Devonian sediments, and a[illegible] lain by Permo-Carboniferous Upper Marine bed

I.I.H.R. Bangalore Centre:-

The centre is entrusted to work on Solanum Viarum Periwinkle, Rose geranium and Patchouli crops. The centre has also initiated studies on Jasminium grandiflorum exploration and domestication studies. It has developed a culture in Solanum viarrium (IIHH 24-II) under release for high density planting.

Extension Work:

Extension booklet and Phamphlets, on cultivation practices on Opium Poppy Palmarosa. Lemagran, Vetiver have been brought out . The centres have participated in Kisan Melas. Seed and planting material are also being distributed to farmers and enterprenure from all the centres . The scientists in co-ordination unit and at the Project station have given T.V. and Radio talks on cultivation and primary processing of these crops important out extention articles in popular Agriculture Journals during the year.
